Summary

Einstein has shown that the matter curves the space-time. In its model, the space-time is a mathematical conceptualization unifying the space and the time that accounts for measured physical phenomena (delay of the perihelion of Mercury, deviation, curvature of light by a large mass, relativity of length and time, propagation of gravitational waves, caused in particular by coalescence of black holes, which materialize by infinitesimal deformations $\Delta L / L$ of space-time ($10^{-21}$)), etc. The question that then comes to mind is whether the mathematical conceptualization of space-time has a physical reality? In this case, what is the material of the fabric of the space-time that undulates or bends under gigantic masses in motion? Where, from a mechanical point of view, can we find an equivalent Young’s modulus $E$ to the fabric of the space-time? A first clue is the Casimir’s force, which tells us that the vacuum of space is not empty ... From recent publications on the subject and simple analogies based on the strength of materials, we will show that if the E-module of space-time exists, it seems incommensurably large whatever the approach considered (elastic plates in 2 dimensions, plates analyzed by a tensor calculation in 4 dimensions, strings, Casimir force). In any case, only a measure of the latter would make it possible to decide definitively.
1) Determination of the Young modulus of the fabric of the space time by analogy with the classical mechanic then with a tensorial calculation in 4 dimensions

1.1) Determination of the base equations

We have shown in previous publications that the relation between the curvature and the energy can be written in 2 dimensions (plate theory) and in 4 dimensions (General relativity theory) [23].

We have so:

- In plate theory in two dimensions:

\[
\Delta U = \frac{D}{2} \left[ \frac{\partial^2 w(x,y)}{\partial x^2} \right]^2 + 2v \frac{\partial^2 w(x,y)}{\partial x \partial y} + 2(1-v) \left( \frac{\partial^2 w(x,y)}{\partial x \partial y} \right)^2 + \left( \frac{\partial^2 w(x,y)}{\partial y^2} \right)^2 \Delta x \Delta y (1)
\]

Or again, if we put following a more clearly way the curvature in one side and the energy on the other side of the equation, we obtain:

\[
\left[ \frac{1}{R_x} \right]^2 + \left[ \frac{1}{R_y} \right]^2 + 2(1-v) \left[ \frac{1}{R_{xy}} \right]^2 + 2v \left( \frac{1}{R_x} \frac{1}{R_y} \right) = \frac{24(1-v^2)}{Eh^3 \times \Delta x \Delta y} \Delta U (2)
\]

- Following the general relativity, if we put following a more clearly way the curvature of the space time in one side and the stress energy tensor on the other side of the equation, we obtain:

\[
R_{\mu\nu} - \frac{1}{2} g_{\mu\nu} R + \Lambda g_{\mu\nu} = \frac{8\pi G}{c^4} T_{\mu\nu} (3)
\]

With for memory for the stress energy tensor:

\[
T_{\mu\nu} = \begin{bmatrix}
mc^2 & \rho cv_x & \rho cv_y & \rho cv_z \\
\rho cv_x & \sigma_{xx} & \tau_{xy} & \tau_{xz} \\
\rho cv_y & \tau_{xy} & \sigma_{yy} & \tau_{yz} \\
\rho cv_z & \tau_{xz} & \tau_{yz} & \sigma_{zz}
\end{bmatrix} (4)
\]

If we suppose that the space-time fabric is a superposition of thin sheets of thickness \(L_p\) (with \(L_p\) the length of Planck), we obtain a multi sandwich universe.

It is then possible by analogy between the two models (Einstein’s general relativity and the plate theory in strength of materials) to find an evaluation of the Young’s modulus \(E\) of the space-time \(E\) (N / m²).

To do this, it is sufficient, to compare the curvature of the two equations (2) and (3). We obtain then:

\[
\frac{24(1-v^2)}{Eh^3 \times \Delta x \Delta y} \approx \frac{8\pi G}{c^4} \times \frac{U}{V} (5)
\]

By simplifying by \(U / V\) on each side of the equation, we obtain:

\[
\frac{8\pi G}{c^4} \approx \frac{24(1-v^2)}{Eh^2} (6)
\]

The dimensional equation allows us to verify that this equivalence is reasonable:

\[
\frac{L^3}{MT^2 L^4} = \frac{1}{M} \frac{L^3}{T^2} \frac{1}{L^2 T^2} L^2 = \frac{1}{M} \frac{L^3}{T^2} = \frac{s^2}{kgm} (7)
\]
We can extract from the equation (6) an estimation of the Young's modulus $E$ of the space-time fabric.

$$E_{\text{fabric of the space time}} = \frac{24(1 - v^2)c^4}{h^28\pi G} \quad (8)$$

By introducing $\kappa = \frac{8\pi G}{c^4}$ (9)

We obtain the Young modulus $E$ of the space-time fabric by analogy with a thin sheet of thickness $h$ of the space-time in bending:

$$E_{\text{fabric of the space time}} = \frac{24(1 - v^2)h^2}{\kappa} \quad (10)$$

$v$ is the Poisson’s ratio of the space-time.

If we assume that the thickness of the thin sheet is equal to the length of Planck $L_p$ (smaller than it is possible to reach), we obtain:

$$E_{\text{fabric of the space time}} = \frac{24(1 - v^2)}{L_p^2\kappa} \quad (11) \text{ with } L_p = \sqrt{\frac{hG}{c^3}} \quad (12) \text{ and } \kappa = \frac{8\pi G}{c^4}$$

It will be noted that this last expression associates the 3 fundamental constants of physics, $c$, $G$ and $\hbar$.

1.2) Numerical application

We apply the formula (11) from the following data:

$v = 0$ (hypothesis)

$G = 6.6726 \times 10^{-11} \text{ m}^3/\text{kg}/\text{s}^2$

$c = 299792458 \text{ m/s}$

$h = 6.62607004 \times 10^{-34} \text{ m}^2 \text{ kg/s}$

$\kappa = 2.07651 \times 10^{-43} \text{ s}^2/(\text{kg} \cdot \text{m})$

$L_p = 1.62 \times 10^{-35} \text{ m}$

This results for the Young's modulus $E$ is so:

$$E_{\text{space time fabric}} = 4.4247E^{+113} \text{ N/m}^2$$

We can see the extremely high value of this young modulus following this approach.
1.3) Comparison of the obtained results with the state of the art—tensorial calculation of a plate in 4 dimensions

In the publication [5]: “The Mechanics of Spacetime (A Solid Mechanics Perspective on the Theory of General Relativity)” T G Tenev and M F Horstemeyer” we have an expression of young modulus.

The same approach was developed, but this time considering a plate in 4 dimensions and performing the tensor calculations. The authors arrive at the following expression:

\[ Y = 2(1 + \nu)\mu \]

With \( \mu = \frac{12}{L_p^2\kappa} \) and with \( \kappa = \frac{8\pi G}{c^4} \) and \( L_p = \frac{hG}{\sqrt{c^3}} \) and \( \nu = 1 \)

See. Formula 3.12 or 4.45 following the date of publication [5] considered with \( \nu = 1 \):

\[ Y = E_{space\ time\ fabric} = \frac{48}{L_p^2\kappa} = \frac{24(1 + \nu)}{L_p^2\kappa} \] (14)

\[ E_{space\ time\ fabric\ (\nu=1)} = 8.8495E^{+113} \text{ N/m}^2 \]

By taking \( \nu = 0 \) (Poisson’s ratio) to compare with our results, we obtain:

\[ E_{space\ time\ fabric\ (\nu=0)} = \frac{24}{L_p^2\kappa} = \frac{24(1 + \nu)}{L_p^2\kappa} \] (15)

\[ E_{space\ time\ fabric\ (\nu=0)} = 4.43E^{+113} \text{ N/m}^2 \]

2) Determination of the Young modulus of the space time by an approach of wave transmit by the elastic material constituting the fabric of the universe

2.1) Determination of the base equations

We can consider the space-time fabric as an assembly of extremely fine and short strings (see Figure 1). We also consider that it is this fabric (invisible to our eyes since it is made up of elements of the size of Planck’s length) which transmits the gravitational waves and bends in the presence of matter.

![Figure 1 – Fabric of the space time made of an assembly of thin strings that have a young modulus E and a section S –](image)
By definition of a force we have:

$$F = my \quad (16)$$

By denoting by $S$ the section of the string and $\rho$ the density of the material constituting it, we denote by $u(x,t)$ the displacement of a point of a string:

$$\rho S \times \Delta x \times \frac{\partial^2 u(x,t)}{\partial t^2} = F(x + \Delta x) - F(x) \quad (17)$$

In addition:

$$F(x + \Delta x) = F(x) + \frac{\partial F(x)}{\partial x} \Delta x \quad (18)$$

By introducing the expression (18) into the expression (17) we obtain:

$$\rho S \times \frac{\partial^2 u(x,t)}{\partial t^2} = \frac{\partial F(x)}{\partial x} \quad (19)$$

In addition, the Hooke law allows to write:

$$F(x) = \sigma S = E \varepsilon S \quad (20)$$

By definition of a strain we have:

$$\varepsilon = \frac{\partial u(x)}{\partial x} \quad (21)$$

$$F(x) = \sigma S = E \varepsilon S = ES \frac{\partial u(x)}{\partial x} \quad (22)$$

So for a plane wave by introducing the equation (22) in the equation (19) we obtain:

$$\rho S \times \frac{\partial^2 u(x,t)}{\partial t^2} = ES \frac{\partial^2 u(x)}{\partial x^2} \quad (23)$$

We obtain the d’Alembert’s equation:

$$\frac{\rho}{E} \times \frac{\partial^2 u(x,t)}{\partial t^2} = \frac{\partial^2 u(x)}{\partial x^2} \quad (24)$$

By definition of a strain, we obtain for a plane wave:

$$\frac{\partial u(x,t)}{\partial x} = \varepsilon(x,t) = -\frac{a}{c} f'(t - \frac{x}{c}) \quad (25)$$

And by the Hook law we obtain also:

$$F(x) = \sigma S = E \varepsilon S$$

$$\sigma(x,t) = -\frac{aE}{c} f'(t - \frac{x}{c}) \quad (26)$$

$$\frac{\partial^2 u(x,t)}{\partial x^2} = \frac{a}{c^2} f''(t - \frac{x}{c}) \quad (27)$$

In addition we have:
\[ \frac{\partial u(x, t)}{\partial t} = a \times f'(t - \frac{x}{c}) \]  \hspace{1cm} (28)

\[ \frac{\partial^2 u(x, t)}{\partial t^2} = a \times f''(t - \frac{x}{c}) \]  \hspace{1cm} (29)

If we introduce these two equations (27) and (29) in the d’Alembert’s formula we obtain:

\[ \frac{\partial}{E} a \times f''(t - \frac{x}{c}) = \frac{a}{c^2} f''(t - \frac{x}{c}) \]  \hspace{1cm} (30)

And finally we obtain:

\[ \frac{\rho}{E} = \frac{1}{c^2} \]  \hspace{1cm} (31)

We can so deduce from the expression (31) the equivalent young modulus of the fibers that constitute the fabric of the space time.

\[ \frac{\rho}{E} = \frac{1}{c^2} \Rightarrow E = \rho c^2 \]  \hspace{1cm} (32)

If we consider that the space-time fabric consists of an infinity of these fibers / cords and that the gravitational waves propagate at the speed of light, we can evaluate the Young-E modulus of the space-time.

2.2) Numerical application (cf. [30])

We envisage two hypotheses, because the state of the art of current physics gives two values of the energy density of the vacuum.

a) **Hypothesis n°1 : the vacuum energy comes of the cosmologic constant**

The vacuum energy density: \( \rho_{\text{cosmologic}} \) is \( 1 \times 10^{-9} \text{ J/m}^3 \)

The vacuum density from \( E_v = mc^2 \Rightarrow E_v/c^2 = m \) that imply \( \rho_{\text{cosmologic}} = 1.11 \times 10^{-26} \text{ kg/m}^3 \) or \( 10^{-29} \text{ g/cm}^3 \)

The equivalent Young modulus E is so \( 1.11 \times 10^{-26} \times 299792458^2 = 1 \times 10^{-9} \text{ N/m}^2 \)

\( E_{\text{fabric of the space time}} = 1 \times 10^{-9} \text{ N/m}^2 \)

b) **Hypothesis n°2 : the vacuum energy comes of the quantum mechanics (field theory)**

The vacuum energy density: \( \rho_{\text{quantique}} \) is \( 1 \times 10^{113} \text{ J/m}^3 \)

The vacuum density from \( E_v = mc^2 \Rightarrow E_v/c^2 = m \) that imply \( \rho_{\text{quantique}} = 1.11 \times 10^{106} \text{ kg/m}^3 \)

The equivalent Young modulus E is so \( 1.11 \times 10^{96} \times 299792458^2 = 1 \times 10^{113} \text{ N/m}^2 \)

\( E_{\text{fabric of the space time}} = 1 \times 10^{113} \text{ N/m}^2 \)

The hypothesis of the quantum mechanics seems more realistic than the cosmologic approach by comparison with the previous results obtained.
3) Determination of the young modulus of the space time by a quantic approach—field theory and Casimir force

3.1) Determination of the base equations

The principle of the Casimir force is given figure 2 below. The vacuum energy of each side of the two plates create a force F which brings them closer together:

![Figure 2 – Definition of the Casimir force confirmed experimentally –](image)

In the case of an approach in one dimension, the energy due to the Casimir force takes the following expression (see [25] and [29]):

\[ U = \frac{\pi \hbar \epsilon}{24L} \] (33)

To obtain the associated force, we use the fact that a force derives of a potential:

\[ F = \text{grad} (U) \] (34)

We obtain by deriving the energy by L:

\[ F = -\frac{\pi \hbar \epsilon}{24L^2} \] (35)

Moreover, we can assimilate the displacement of the two plates due to the Casimir force F to an application of Hooke's law to the space-time fabric located between these two plates (see Figure 3).

In this case, it is possible to consider, between the two surface plates S of a length L, an elastic material of Young's modulus E.

![Figure 3 – Equivalent material (fabric of the space time) located between the two plates loaded by the Casimir Force F–](image)
The strain energy of this type of system loaded with a normal effort \( F \) supposed constant for \( L \) fixed is the following:

\[
U_{\text{elastic strain}} = \frac{1}{2} \int_0^L \left( \frac{N(x)}{ES} \right)^2 dx = \frac{1}{2} \times \frac{F^2 L}{ES} \quad (36)
\]

Assuming that \( U = U_{\text{strain energy}} \) and considering the force \( F \) of Casimir we obtain for the elastic deformation energy of the fabric of the space time located between the two plates:

\[
U_{\text{elastic strain}} = U_{\text{cas}} = \frac{h c \pi}{24L} = \frac{1}{2} \times \left[ \frac{\hbar c \pi}{24L^2} \right]^2 L \quad (37)
\]

So:

\[
\frac{hc \pi}{24L} = \frac{1}{2} \times \frac{h^2 c^2 \pi^2 L}{24^2 ESL^4} \quad (38)
\]

Or again:

\[
\frac{hc \pi}{24L} = \frac{1}{ES} \times \frac{h \ c \pi}{24L} \times \frac{1}{2L^2} \quad (39)
\]

After simplification we obtain:

\[
\frac{1}{L} = \frac{1}{ES} \times \frac{h \ c \pi}{24L} \times \frac{1}{2L^2} \quad (39)
\]

With:

\[
U = \frac{\pi hc}{24L} \quad (40)
\]

So we obtain:

\[
\frac{1}{L} = \frac{1}{2} \times \frac{1}{ES} \times \frac{U}{L^2} \quad (41)
\]

The dimensional equation of \( 1/ES \) is:

\[
\frac{1}{ES} \rightarrow 1 \quad \text{MPa.m}^2 = \frac{1}{MN} m^2 = \frac{1}{kg} m^2 = \frac{s^2}{kgm} = \frac{T^2}{ML} \quad (42)
\]

From the expression (39), we can extract the equivalent Young’s modulus \( E \) from the space-time fabric, which is also here that of the energy of the vacuum created by the disintegrating creations of the particles continuously and instantaneously (see quantum field theory).

\[
E = \frac{h \ c \pi}{48SL^2} \quad (43)
\]

\[
E = \frac{N \ m \times s \times m}{s \times m^2 \times m^2} = \frac{N}{m^2} \quad (44)
\]
3.2) Numerical application:

By hypothesis we consider for \( L \) the Planck distance \( L_p \) in view to have the possibility to compare the results with the previous results obtained \((S = L^2 = L_p^2)\).

\[
\begin{align*}
\hbar &= 1.05457 \times 10^{-34} \text{ J.s} \\
L_p &= 1.616252 \times 10^{-35} \text{ m} \\
c &= 299792458 \text{ m/s}
\end{align*}
\]

\[
E_{\text{tissu de l'espace-temps}} = 3.03 \times 10^{112} \text{ N/m}^2
\]

The results obtained is completely in connection with the previous results obtained.

4) Conclusions

The results are therefore similar regardless of the simplified approaches envisaged (see Table 1 below). The Young-E modulus of space-time fabric therefore seems extremely large. \( E \) seems to be of the order \( 1 \times 10^{113} \text{ N/m}^2 \). This remains to be confirmed by experience and measurement.
