Abstract : This work uses a combinatorial identity involving Stirling’s numbers of the second kind to prove and generalize Wilson’s theorem in an original manner. Then, again using this relation, we show new characterizations of Carmichael’s numbers.

Keywords : Stirling Numbers, Carmichael Numbers, Wilson’s Theorem.
AMC Classification : 11B73, 05A18.

3 Characterizations of Carmichael’s numbers
4 Conclusion

1 New proof of the Wilson’s theorem

Here, we will show the Wilson’s theorem in a combinatorial way, i.e. without going through the traditional classes of congruences met in the literature. We will use the identity \( \Phi \) below - a subtraction between two known combinatorial relations - to make emerge congruences properties
in a visible way.

*Wilson’s theorem*: if $n + 1$ prime, then $n! + 1 \equiv 0 \pmod{n + 1}$

**Proof**:

$\forall n \geq 1$, we have :

$$\sum_{i=0}^{n} (-1)^i C_n^i (X + i)^n = (-1)^n n! \quad (*)$$

This classical identity is obtained from the $n$-th finite difference of the polynomial $X^n$ [5]. One starts then from the relation obtained by setting : $X = 0$ in $(*)$, that is to say :

$$\sum_{i=0}^{n} (-1)^i C_n^i i^n = (-1)^n n! \quad (**)$$

Then, by deriving $k$ times $(*)$ for $k > 1$, we get :

$$\sum_{i=0}^{n} (-1)^i C_n^i (X + i)^n = 0$$

Hence, setting $X = 0$ :

$$\sum_{i=0}^{n} (-1)^i C_n^i i^n = 0$$

In other words, $\forall \alpha$ integer, $\alpha < n$ :

$$\sum_{i=0}^{n} (-1)^i C_n^i i^{\alpha} = 0 \quad (\Delta)$$

Now, let us cut off to $(**)$, member with member, the arithmetic equation :

$$\sum_{i=0}^{n} (-1)^i C_n^i = 0$$

obtained by posing $\alpha = 0$ in $(\Delta)$.

Hence, for $n + 1$ an odd prime number $\geq 3$ (thus $n$ even) :

$$\sum_{i=1}^{n} (-1)^i C_n^i (i^n - 1) = n! + 1 \quad (\Phi)$$

Using the little Fermat’s theorem, one sees that :

$\forall i = 1...n,$
\[ i^n - 1 \equiv 0 \mod{n + 1} \]

From which:

\[ n! + 1 \equiv 0 \mod{n + 1} \]

Q.E.D.

Always thanks to Φ, we note that if \( n + 1 \) divides the terms \( i^n - 1 \), \( \forall i \) varying from 1 to \( n \), then it divides \( n! + 1 \). Thus, according to the equivalence of the Wilson’s theorem, \( n + 1 \) is prime - this result can also be found by using the theorem of Bézout.

We discovered later another proof of the Wilson’s theorem starting from (**) [2]. But this proof differs from ours in that it uses initially the formula:

\[ C_{n+1}^i = C_n^i + C_n^{i-1} \]

and the following result: for all prime number \( n + 1 \) and \( i = 1...n \),

\[ C_{n+1}^i \equiv 0 \mod{n + 1} \]

Then:

\[ C_n^i + C_n^{i-1} \equiv 0 \mod{n + 1} \]
\[ C_n^i \equiv -C_n^{i-1} \mod{n + 1} \]
\[ C_n^i \equiv (-1)^{i-1}C_n^i \equiv (-1)^i \mod{n + 1} \]

From which:

\[ C_n^i \equiv (-1)^i \mod{n + 1} \]
\[ (-1)^iC_n^i i^n \equiv (-1)^i(-1)^i i^n \equiv i^n \mod{n + 1} \]
\[ \sum_{i=0}^{n} (-1)^iC_n^i i^n \equiv \sum_{i=1}^{n} i^n \equiv (-1)^n n! = n! \mod{n + 1} \]

Then, the little Fermat’s theorem is applied: \( \forall i = 1...n \),

\[ i^n \equiv 1 \mod{n + 1} \]

Finally:

\[ \sum_{i=1}^{n} i^n \equiv n \equiv n! \equiv -1 \mod{n + 1} \]
This proof involves two different types of congruences, whereas we only use that of Fermat. Our method directly makes rise the result in a visual way while revealing the numbers of the form $k^n - k$ for all $k = 1 \ldots n$, and it is systematically as we will proceed thereafter to deduce new results of congruence.

2 Generalizations of Wilson’s theorem

We have the following result using the Stirling numbers of the second kind.

**Theorem S :**

Let $m + 1$ be a prime. Then, $\forall n \leq m$,

$$(-1)^n n! \left\{ \begin{array}{c} m \\ n \end{array} \right\} + 1 \equiv 0 \pmod{m + 1}$$

where the $\left\{ \begin{array}{c} m \\ n \end{array} \right\}$ are the Stirling’s numbers of second kind, giving the number of $n$-partitions of a set of $m$ elements.

**Proof :**

The Stirling numbers of the second kind $\left\{ \begin{array}{c} m \\ n \end{array} \right\}$ verify the following classical relation [1] :

$$\sum_{i=0}^{n} (-1)^i C_n^i i^m = (-1)^n n! \left\{ \begin{array}{c} m \\ n \end{array} \right\}$$  \hspace{1cm} (1)

Applying the same method as in our proof of Wilson’s theorem, (1) can be rewritten for all $m + 1$ prime and $n \leq m$ :

$$\sum_{i=1}^{n} (-1)^i C_n^i i^m - 1 = (-1)^n n! \left\{ \begin{array}{c} m \\ n \end{array} \right\} + 1$$  \hspace{1cm} (2)

As again, $\forall i = 1 \ldots n$, $i^m - 1 \equiv 0 \pmod{m + 1}$.

Then,

$$(-1)^n n! \left\{ \begin{array}{c} m \\ n \end{array} \right\} + 1 \equiv 0 \pmod{m + 1}$$

Q.E.D.

One can still push our generalization further using the classical Euler’s totient function $\varphi(n)$ which, to each integer $n$, associates the number of integers lower than $n$ and prime with it.

**Theorem E :**
Let $p, n$ be two integers such that $p > n$ and $\forall i \leq n, \ i \wedge p = 1$.

We have then:

$$(-1)^nn!\left\{\frac{\varphi(p)}{n}\right\} + 1 \equiv 0 \ [p]$$

**Proof:**

Let’s make out first that if $\forall i \leq n, i \wedge p = 1$, we will have, by definition of $\varphi : \varphi(p) \geq n$, then \{ $\varphi(p)$ \} is well-defined.

Besides, we know that the Euler’s totient function allows us to generalize the little Fermat’s theorem in the following way [4]:

$$\forall i, p \text{ with } i \wedge p = 1$$

$$i^{\varphi(p)} - 1 \equiv 0 \ [p]$$

Let then $p$ be an integer such that : $\forall i \leq n, i \wedge p = 1$.

By setting $m = \varphi(p)$ in (2), we obtain:

$$\sum_{i=0}^{n}(-1)^iC_n^i(i^{\varphi(p)} - 1) = (-1)^nn!\left\{\frac{\varphi(p)}{n}\right\} + 1$$

Yet, by hypothesis : $\forall i \leq n, i \wedge p = 1$

then :

$$\forall i \leq n, \ i^{\varphi(p)} - 1 \equiv 0 \ [p]$$

$$\Rightarrow (-1)^nn!\left\{\frac{\varphi(p)}{n}\right\} + 1 \equiv 0 \ [p]$$

*Q.E.D.*

**Note :** One finds the generalized theorem $S$, by setting $p = m + 1$ with $m + 1$ prime, which implies that : $\varphi(p) = m$.

Thus, the generalizations of the theorems of Wilson and Fermat are directly united in one and the same relation using the Stirling numbers of the second kind. Let us now turn to the characterization of the Carmichael numbers, on the basis of the same combinatorial relations again.
3 Characterizations of Carmichael’s numbers

Definition:

We call Carmichael number every composed and non-negative integer \( \kappa \) verifying the following property:

\[ \forall a \text{ integer}, \quad a^\kappa \equiv a \pmod{\kappa} \]

The Carmichael numbers are also called absolutely pseudo-prime or "Fermat liars" because of their behaviour analogy with prime numbers, so much so that they defeat the Fermat primality test \([3]\). We will prove here a new very simple criterion for characterizing these numbers.

Criterion \( C_1 \):

A composite integer \( \kappa \) is said of Carmichael if and only if:

\[ \forall n \leq \kappa - 1, \quad n! \binom{\kappa}{n} \equiv 0 \pmod{\kappa} \]

Proof:

Let’s proceed in two steps.

Step 1

Let’s prove first that a composite integer \( \kappa \) is of Carmichael if and only if: \( \forall n, \)

\[ n! \binom{\kappa}{n} \equiv 0 \pmod{\kappa} \]

Let us start from the relation (1) already mentioned at any \( n \):

\[ \sum_{i=0}^{n} (-1)^i C_n^i m^i = (-1)^n n! \binom{m}{n} \]

to which we subtract the relation:

\[ \sum_{i=0}^{n} (-1)^i C_n^i \alpha = 0 \]

which is simply proved by setting \( \alpha = 1 \) in the \( \Delta \) formula demonstrated at the beginning of our work.
One gets:

\[
\sum_{i=0}^{n} (-1)^i C_n^i (i^m - i) = (-1)^n n! \left\{ \begin{array}{c} m \\ n \end{array} \right\} \quad (1')
\]

sense \(\Rightarrow\):

Let \(\kappa\) be an integer of Carmichael. It verifies by definition: \(\forall i,\)

\[i^\kappa - i \equiv 0 \quad [\kappa]\]

Yet, for \(m = \kappa\), \((1')\) becomes:

\[
\sum_{i=0}^{n} (-1)^i C_n^i (i^\kappa - i) = (-1)^n n! \left\{ \begin{array}{c} \kappa \\ n \end{array} \right\}
\]

Hence, by linearity of congruence:

\[(-1)^n n! \left\{ \begin{array}{c} \kappa \\ n \end{array} \right\} \equiv 0 \quad [\kappa]\]

That is to say:

\[n! \left\{ \begin{array}{c} \kappa \\ n \end{array} \right\} \equiv 0 \quad [\kappa]\]

sense \(\Leftarrow\):

Let now be a composed integer \(\kappa\) and let’s suppose that: \(\forall n,\)

\[n! \left\{ \begin{array}{c} \kappa \\ n \end{array} \right\} \equiv 0 \quad [\kappa]\]

Let us show by recurrence on \(n\) that: \(\forall n,\)

\[n^\kappa - n \equiv 0 \quad [\kappa]\]

– This is verified for \(n = 0.\)
– Let’s suppose the hypothesis is true for \(n - 1.\)
– We demonstrate it for \(n.\)

From:

\[
\sum_{i=0}^{n} (-1)^i C_n^i (i^\kappa - i) = (-1)^n n! \left\{ \begin{array}{c} \kappa \\ n \end{array} \right\}
\]

We deduce:

\[(-1)^n (n^\kappa - n) + \sum_{i=0}^{n-1} (-1)^i C_n^i (i^\kappa - i) = (-1)^n n! \left\{ \begin{array}{c} \kappa \\ n \end{array} \right\}\]
Then, according to our hypothesis:

$$\forall i \leq n - 1, \ i^\kappa - i \equiv 0 \ [\kappa]$$

we get:

$$\sum_{i=0}^{n-1} (-1)^i C_n^i (i^\kappa - i) \equiv 0 \ [\kappa]$$

and:

$$n!\{\kappa\}_n \equiv 0 \ [\kappa]$$

Hence:

$$n^\kappa - n \equiv 0 \ [\kappa]$$

The step 1 is completed. The obtained criterion can yet be simplified as follows.

**Step 2**

Let us prove that: \(\kappa\) is of Carmichael if and only if: \(\forall n \leq \kappa - 1, \ n!\{\kappa\}_n \equiv 0 \ [\kappa]\)

By definition of \(\kappa\), the sense \(\Rightarrow\) is immediate. As for the sense \(\Leftarrow\), let us suppose that:

$$\forall n \leq \kappa - 1, \ n!\{\kappa\}_n \equiv 0 \ [\kappa]$$

We know that: \(\forall n \geq \kappa, \ n! \equiv 0 \ (\kappa)\).

Then:

$$\forall n \geq \kappa, \ n!\{\kappa\}_n \equiv 0 \ (\kappa)$$

$$\Rightarrow \forall n, \ n!\{\kappa\}_n \equiv 0 \ (\kappa)$$

So, by definition, \(\kappa\) is a Carmichael number.

**Q.E.D.**

In the general case, let us prove the following result:
Lemma $G$:

For all integers $n, m, p$,

\[(\forall k \in [0, n], \quad km - k \equiv 0 \quad [p]) \iff (\forall l \in [0, n], \quad ll! \binom{m}{l} \equiv 0 \quad [p])\]

Proof:

We start again from (1'):

\[\sum_{i=0}^{n} (-1)^i C^n_i (i^m - i) = (-1)^n n! \binom{m}{n}\]

Let's set integers $n, m, p$.

- sense $\Rightarrow$

We suppose that:

\[\forall k \in [0, n], \quad km - k \equiv 0 \quad [p]\]

Then, according to (1') and by linearity of the congruence:

\[\forall l \in [0, n], \quad \sum_{i=0}^{l} (-1)^i C^l_i (i^m - i) = (-1)^l l! \binom{m}{l} \equiv 0 \quad [p]\]

- sense $\Leftarrow$

Let us suppose:

\[\forall l \in [0, n], \quad ll! \binom{m}{l} \equiv 0 \quad [p]\]

Here, we remind the classical binomial inversion: given two sequences $u_n$ and $v_n$, we have

\[u_n = \sum_{i=0}^{n} C^n_i v_i \iff v_n = \sum_{i=0}^{n} (-1)^{n-i} C^n_i u_i\]

We can apply the binomial inversion to (1') to get:

\[\forall k, m, \quad \sum_{l=0}^{k} C^k_l l! \binom{m}{l} = km - k\]

Then, by hypothesis, $\forall k \in [0, n]$ we have:
Thus, by linearity of congruence:

\[ \forall l \in [0, k], \quad l! \binom{m}{l} \equiv 0 \quad [p] \]

Q.E.D.

This lemma G highlights that a transfer of arithmetic properties is possible in both directions between \( \{k^m - k\}_{k \in \mathbb{N}} \) numbers and Stirling numbers of the second kind. It allows us to prove in another manner this equivalent well-known definition of Carmichael numbers, which limits the number of congruences they must satisfy [3] :

A composite integer \( \kappa \) is a Carmichael number if and only if:

\[ \forall a \leq \kappa - 1, \quad a^\kappa - a \equiv 0 \quad [\kappa] \]

Proof:

We just apply lemma G to criterion \( C_1 \), with \( \kappa \) a Carmichael number and \( m = \kappa, n = \kappa - 1, p = \kappa. \) Q.E.D.

Yet, we have a stronger result:

Criterion \( C_2 \):

Let \( m \) be a composite square free integer whose largest prime factor is \( p \). Then, \( m \) is a Carmichael number if and only if:

\[ \forall a \leq p - 1, \quad a^m - a \equiv 0 \quad [m] \]

or equivalently,

\[ \forall a \leq p - 1, \quad a! \binom{m}{a} \equiv 0 \quad [m] \]

Proof:
At first, we note that this criterion is compatible with the properties of Carmichael numbers: we know that, according to the Korselt’s criterion [3], a Carmichael number is always square free. Besides, it has at least three prime factors.

Now, we have $\forall a \geq p, a! \equiv 0 \mod m$ : indeed, since by hypothesis $m$ is square free and its largest prime factor is $p$, all its prime factors are smaller than $a$ and of exponent 1. Thus, their product $m$ divides $a!$ and, a fortiori, $a!\{m\}_a$. So, thanks to criterion $C_2$, there is no need to use congruences:

$$a!\{m\}_a \equiv 0 \mod m$$

for all $a \geq p$.

According to lemma G, this result is equivalent to: $\forall a \leq p - 1$,

$$a^m - a \equiv 0 \mod m$$

At the end of the day, we can state an even stronger result.

**Criterion $C_3$ :**

Let $m$ be a composite square free integer such that:

$$m = p_1.p_2.p_3...p_k$$

Then, the following propositions are equivalent:

1. $m$ is a Carmichael number.

2. $\forall j \in [1,k], \forall a \leq p_j - 1$,

$$a^m - a \equiv 0 \mod p_j$$

3. $\forall j \in [1,k], \forall a \leq p_j - 1$,

$$a!\{m\}_a \equiv 0 \mod p_j$$

4. $\forall j \in [1,k], \forall a \leq p_j - 1$,

$$\{m\}_a \equiv 0 \mod p_j$$

**Proof :**

Again, it is easier to consider first the $a!\{m\}_a$ numbers because of the factorial’s properties. For each prime factor $p_j$ of $m$, we have indeed:
\[ \forall a \leq p_j - 1, \ a! \left\{ \frac{m}{a} \right\} \equiv 0 \ [p_j] \Leftrightarrow \forall a \in \mathbb{N}, \ a! \left\{ \frac{m}{a} \right\} \equiv 0 \ [p_j] \]

given that \( \forall a \geq p_j, \ a! \equiv 0 \ [p_j] \).

Besides :

\[ \forall j \in [1, k], \forall a \in \mathbb{N}, \ a! \left\{ \frac{m}{a} \right\} \equiv 0 \ [p_j] \Leftrightarrow \forall a \in \mathbb{N}, \ a! \left\{ \frac{m}{a} \right\} \equiv 0 \ [m] \]

since \( m \) is square free with : \( m = p_1 \cdot p_2 \cdot p_3 \ldots p_k \). According to criterion \( C_1 \), the last member of the equivalence above characterizes the Carmichael numbers.

Then, \( m \) is a Carmichael number if and only if \( \forall j \in [1, k] \), we have :

\[ \forall a \leq p_j - 1, \ a! \left\{ \frac{m}{a} \right\} \equiv 0 \ [p_j] \]

This proves \((1) \Leftrightarrow (3)\). Besides, according to lemma \( G \), proposition \( (3) \) is equivalent to \( (2) \).

At last, \( \forall j \in [1, k] \), \( p_j \) is a prime number then, if \( a < p_j \), \( a! \) and \( p_j \) are relatively prime, which implies that \( p_j \) divides \( a! \left\{ \frac{m}{a} \right\} \) if and only if \( p_j \) divides \( \left\{ \frac{m}{a} \right\} \) : we have proved that \( (3) \Leftrightarrow (4) \).

\( Q.E.D. \)

Applications :

- The smallest Carmichael number with seven prime factors is \( m = 5394826801 = 7 \times 13 \times 17 \times 23 \times 31 \times 67 \times 73 \). Then, according to criterion \( C_2 \), \( m \) is a Carmichael number if and only if \( m \) divides all the \( a^m - a \) for \( a = 1, \ldots, a = p \), where \( p = 73 \) is the largest prime factor of \( m \). No need in theory to check the congruences from \( a = 1 \) to \( a = 5394826801 \).

- In the same way, \( m = 1436697831295441 = 11 \times 13 \times 19 \times 29 \times 31 \times 37 \times 41 \times 43 \times 71 \times 127 \) is the smallest Carmichael number with ten prime factors. Then, congruence checks should be performed only up to \( a = 127 \) instead of \( a = 1436697831295441 \).

4 Conclusion

We started from the same combinatorial relation :

\[ \sum_{i=0}^{n} (-1)^i \binom{n}{i}^2 n! = (-1)^n n! \]

that we slightly transformed to prove directly and generalize the Wilson’s theorem, then to propose several simplified characterizations of the Carmichael numbers.
