EQUIVARIANT EXTENSIONS OF $\mathbb{G}_a$-TORSORS OVER PUNCTURED SURFACES

ADRIEN DUBOULOZ, ISAC HEDÉN, AND TAKASHI KISHIMOTO

Abstract. Motivated by the study of the structure of algebraic actions the additive group on affine threefolds $X$, we consider a special class of such varieties whose algebraic quotient morphisms $X \to X/\mathbb{G}_a$ restrict to principal homogeneous bundles over the complement of a smooth point of the quotient. We establish basic general properties of these varieties and construct families of examples illustrating their rich geometry. In particular, we give a complete classification of a natural subclass consisting of threefolds $X$ endowed with proper $\mathbb{G}_a$-actions, whose algebraic quotient morphisms $\pi : X \to X/\mathbb{G}_a$ are surjective with only isolated degenerate fibers, all isomorphic to the affine plane $\mathbb{A}^2$ when equipped with their reduced structures.

Introduction

Algebraic actions of the complex additive group $\mathbb{G}_a = \mathbb{G}_a, \mathbb{C}$ on normal complex affine surfaces $S$ are essentially fully understood: the ring of invariants $\mathcal{O}(S)^{\mathbb{G}_a, \mathbb{C}}$ is a finitely generated algebra whose spectrum is a smooth affine curve $C = S/\mathbb{G}_a$, and the inclusion $\mathcal{O}(S)^{\mathbb{G}_a, \mathbb{C}} \subset \mathcal{O}(S)$ defines a surjective morphism $\pi : S \to C$ whose general fibers coincide with general orbits of the action, hence are isomorphic to the affine line $\mathbb{A}^1$ on which $\mathbb{G}_a$ acts by translations. The degenerate fibers of such $\mathbb{A}^1$-fibrations are known to consist of finite disjoint unions of smooth affine curves isomorphic to $\mathbb{A}^1$ when equipped with their reduced structure. A complete description of isomorphism classes of germs of invariant open neighborhoods of irreducible components of such fibers was established by Fieseler [8].

In contrast, very little is known so far about the structure of $\mathbb{G}_a$-actions on complex normal affine threefolds. For such a threefold $X$, the ring of invariants $\mathcal{O}(X)^{\mathbb{G}_a}$ is again finitely generated [13] and the morphism $\pi : X \to S$ induced by the inclusion $\mathcal{O}(X)^{\mathbb{G}_a} \subset \mathcal{O}(X)$ is an $\mathbb{A}^1$-fibration over a normal affine surface $S$. But in general, $\pi$ is neither surjective nor equidimensional. Furthermore, it can have degenerate fibers over closed subsets of pure codimension 1 as well as of codimension 2. All of these possible degeneration are illustrated by the following example:

The restriction of the projection $pr_{x,y}$ to the smooth threefold $X = \{x^2(x-1)v + yu^2 - x = 0\}$ in $\mathbb{A}^4$ is an $\mathbb{A}^1$-fibration $\pi : X \to \mathbb{A}^2$ which coincides with the algebraic quotient morphism of the $\mathbb{G}_a$-action on $X$ associated to the locally nilpotent derivation $\partial = x^2(x-1)\partial_u - 2yu\partial_v$ of its coordinate ring. The restriction of $\pi$ over the principal open subset $x^2(x-1) \neq 0$ of $\mathbb{A}^2$ is a trivial principal $\mathbb{G}_a$-bundle, but the fibers of $\pi$ over the points $(1,0)$ and $(0,0)$ are respectively empty and isomorphic to $\mathbb{A}^2$. Furthermore, for every $y_0 \neq 0$, the inverse images under $\pi$ of the points $(0,y_0)$ and $(1,y_0)$ are respectively isomorphic to $\mathbb{A}^1$ but with multiplicity 2, and to the disjoint union of two reduced copies of $\mathbb{A}^1$.

Partial results concerning the structure of one-dimensional degenerate fibers of $\mathbb{G}_a$-quotient $\mathbb{A}^1$-fibrations were obtained by Gurjar-Masuda-Miyanishi [9]. In the present article, as a step towards the understanding of the structure of two-dimensional degenerate fibers, we consider a particular type of non equidimensional surjective $\mathbb{G}_a$-quotient $\mathbb{A}^1$-fibrations $\pi : X \to S$ which have the property that they restrict to $\mathbb{G}_a$-torsors over the complement of a finite set of smooth points in $S$. These are simpler than the general case illustrated in the previous example since they do not admit additional degeneration of their fibers over curves in $S$ passing through the given points. The local and global study of some classes of such fibrations was initiated by the second author [10]. He constructed in particular many examples of $\mathbb{G}_a$-quotient $\mathbb{A}^1$-fibrations on smooth affine threefolds $X$ with image $\mathbb{A}^2$ whose restrictions over the complement of the

\end{itemize}
origin are isomorphic to the geometric quotient $\text{SL}_2 \to \text{SL}_2/\mathbb{G}_a$ of $\text{SL}_2$ by the action of unitary upper triangular matrices.

One of the simplest examples of this type is the smooth threefold $X_0 \subset \mathbb{A}^5_{x,y,p,q,r}$ defined by the equations

$$
X_0 : \begin{cases}
x x - y q &= 0 \\
y p - x (q - 1) &= 0 \\
p r - q (q - 1) &= 0
\end{cases}
$$

and equipped with the $\mathbb{G}_a$-action associated to the locally nilpotent $\mathbb{C}[x, y]$-derivation $x^2 \partial_p + y x \partial_q + y^2 \partial_r$ of its coordinate ring. The equivariant open embedding $\text{SL}_2 = \{ x y = u v = 1 \} \to X_0$ is given by $(x, y, u, v) \mapsto (x, y, x u, x v, y v)$. The $\mathbb{G}_a$-quotient morphism coincides with the surjective $\mathbb{A}^1$-fibration $\pi_0 : \text{pr}_{x,y} : X_0 \to \mathbb{A}^2$. Its restriction over $\mathbb{A}^2 \setminus \{(0,0)\}$ is isomorphic to the quotient morphism $\text{SL}_2 \to \text{SL}_2/\mathbb{G}_a$, while its fiber over $(0,0)$ is the smooth quadric $\{ p r - q (q - 1) = 0 \} \subset \mathbb{A}^3_{p,q,r}$, isomorphic to the quotient $\text{SL}_2/\mathbb{G}_a$ of $\text{SL}_2$ by the action of its diagonal torus (see Example 2.1). A noteworthy property of this example is that the $\mathbb{G}_a$-quotient morphism $\pi : X_0 \to \mathbb{A}^2$ factors through a locally trivial $\mathbb{A}^1$-bundle $\rho : X_0 \to \mathbb{A}^2$ over the the blow-up $\tau : \mathbb{A}^2 \to \mathbb{A}^2$ of the origin.

It is a general fact that every irreducible component of a degenerate fiber of pure codimension one of a $\mathbb{G}_a$-quotient $\mathbb{A}^1$-fibration $\pi : X \to S$ on a smooth affine threefold is an $\mathbb{A}^1$-uniruled affine surface (see Proposition 1.3). We do not know whether every $\mathbb{A}^1$-uniruled surface can be realized as an irreducible component of the degenerate fiber of a $\mathbb{G}_a$-extension. But besides the smooth affine quadric $\text{SL}_2/\mathbb{G}_a$ appearing in the previous example, the following one confirms that the affine plane $\mathbb{A}^2$ can also be realized (see also Examples 1.4 and 1.5 for other types of surfaces that can be realized): Let $X_1 \subset \mathbb{A}^5_{x,y,z_1,z_2,w}$ be the smooth affine threefold defined by the equations

$$
X_1 : \begin{cases}
x w - y (z_1 + 1) &= 0 \\
x z_2 - z_1 (y z_1 + 1) &= 0 \\
z_1 w - y z_2 &= 0,
\end{cases}
$$

equipped with the $\mathbb{G}_a$-action associated to the locally nilpotent $\mathbb{C}[x, y]$-derivation $x \partial_{z_1} + (2 y z_1 + 1) \partial_{z_2} + y^2 \partial_w$ of its coordinate ring. The morphism $\text{SL}_2 \to X_1$ given by $(x, y, u, v) \mapsto (x, y, u, w, y v)$ is equivariant open embedding. The $\mathbb{G}_a$-quotient morphism coincides with the surjective $\mathbb{A}^1$-fibration $\pi_1 = \text{pr}_{x,y} : X_1 \to \mathbb{A}^2$, whose fiber over the origin is the affine plane $\mathbb{A}^2 = \text{Spec}(\mathbb{C}[z_2, w])$ and whose restriction over $\mathbb{A}^2 \setminus \{(0,0)\}$ is again isomorphic to the quotient morphism $\text{SL}_2 \to \text{SL}_2/\mathbb{G}_a$. A special additional feature is that the $\mathbb{G}_a$-action on $X_1$ extending that on $\text{SL}_2$ is not only fixed point free but actually proper: its geometric quotient $X_1/\mathbb{G}_a$ is separated. One can indeed check that $X_1/\mathbb{G}_a$ is isomorphic to the complement $\mathbb{A}^2 \setminus \{ o_1 \}$ of a point $o_1$ supported on the exceptional divisor $E$ of the blow-up $\tilde{\mathbb{A}}^2$ of $\mathbb{A}^2$ at the origin (see Example 3.2).

Relaxing the hypothesis that the $\mathbb{A}^1$-fibration $\pi : X \to S$ arises as the quotient of a $\mathbb{G}_a$-action on an affine threefold $X$ to consider the broader problem of describing the geometry of degeneration of $\mathbb{A}^1$-fibrations over irreducible closed subsets of pure codimension two of their base, we are led to the following more general notion:

**Definition.** Let $(S, o)$ be a pair consisting of a normal separated 2-dimensional scheme $S$ essentially of finite type over a field $k$ of characteristic zero and of a closed point $o$ contained in the smooth locus of $S$. A $\mathbb{G}_a$-extension of a $\mathbb{G}_a$-torsor $\rho : P \to S \setminus \{ o \}$ is a $\mathbb{G}_a$-equivariant open embedding $j : P \hookrightarrow X$ into an integral scheme $X$ equipped with a surjective morphism $\pi : X \to S$ of finite type and a $\mathbb{G}_a,S$-action, such that the commutative diagram

$$
\begin{array}{ccc}
P & \xmapsto{j} & X \\
\rho \downarrow & & \downarrow{\pi} \\
S \setminus \{ o \} & \longrightarrow & S
\end{array}
$$

is cartesian.

The examples $X_0$ and $X_1$ above provide motivation to study the following natural classes of $\mathbb{G}_a$-extensions $\pi : X \to S$ of a $\mathbb{G}_a$-torsor $\rho : P \to S \setminus \{ o \}$, which are arguably the simplest possible types of $\mathbb{G}_a$-extensions from the viewpoints of their global geometry and of the properties of their $\mathbb{G}_a$-actions:
- (Type I) Extensions for which $\pi$ factors through a locally trivial $\mathbb{A}^1$-bundle over the blow-up $\tau: \tilde{S} \to S$ of the point $o$, the fiber $\pi^{-1}(o)$ being then the total space of a locally trivial $\mathbb{A}^1$-bundle over the exceptional divisor of $\tau$.

- (Type II) Extensions for which $\pi^{-1}(o)_{\text{red}}$ is isomorphic to the affine plane $\mathbb{A}^2_o$ over the residue field $\kappa$ of $S$ at $o$, $X$ is smooth along $\pi^{-1}(o)$ and the $\mathbb{G}_a,S$-action on $X$ is proper.

The first main result of this article, Proposition 2.3 and Theorem 2.5, is a complete description of $\mathbb{G}_a$-extensions of Type I together with an effective characterization of which among them have the additional property that the morphism $\pi: X \to S$ is affine. Our second main result, Theorem 3.7, consists of a classification of $\mathbb{G}_a$-extensions of Type II, under the additional assumption that the morphism $\pi: X \to S$ is quasi-projective. More precisely, given a $\mathbb{G}_a$-torsor $\rho: P \to S \setminus \{o\}$ and a $\mathbb{G}_a$-extension $\pi: X \to S$ with proper $\mathbb{G}_a,S$-action and reduced fiber $\pi^{-1}(o)_{\text{red}}$ isomorphic to $\mathbb{A}^2_o$, we establish that the possible geometric quotients $S' = X/\mathbb{G}_a$ belong to a very special class of surfaces isomorphic to open subsets of blow-ups of $S$ with centers over $o$ which we fully describe in § 3.1. We show conversely that every such surface is indeed the geometric quotient of a $\mathbb{G}_a$-extension of $\rho: P \to S \setminus \{o\}$ with the desired properties.

In a second step, we tackle the question of existence of $\mathbb{G}_a$-extensions $\pi: X \to S$ of Type II for which the structure morphism $\pi$ is not only quasi-projective but affine. Our method to produce extensions with this property is inspired by the observation that the threefolds $X_0$ and $X_1$ above are not only birational to each other due to the property that they both contain $\text{SL}_2$ as open subset, but in fact that the birational morphism

$$\eta: X_1 \to X_0, \quad (x, y, z_1, z_2, w) \mapsto (x, y, p, q, r) = (x, y, xz_1, yz_1 + 1, w)$$

expresses $X_1$ as a $\mathbb{G}_a$-equivariant affine modification of $X_0$ in the sense of Kaliman and Zaidenberg [11]. This suggests that extensions of Type II for which $X$ is affine over $S$ could be obtained as equivariant affine modification in a suitable generalized sense from extensions of Type I with the same property. Using this technique, we are able to show in Theorem 3.8 that for each possible geometric quotient $S'$ above, there exist $\mathbb{G}_a$-extensions $\pi: X \to S$ of $\rho: P \to S \setminus \{o\}$ with geometric quotient $X/\mathbb{G}_a = S'$ such that $\pi$ is an affine morphism.

As an application towards the initial question of the structure $\mathbb{G}_a$-quotient $\mathbb{A}^1$-fibrations on affine threefolds, we in particular derive from this construction the existence of uncountably many pairwise non-isomorphic smooth affine threefolds $X$ endowed with proper $\mathbb{G}_a$-actions, containing $\text{SL}_2$ as an invariant open subset with complement $\mathbb{A}^2$, whose geometric quotients are smooth quasi-projective surfaces which are not quasi-affine, and whose algebraic quotients are all isomorphic to $\mathbb{A}^2$.

The scheme of the article is the following. The first section begins with a review of general properties of $\mathbb{G}_a$-extensions. We then set up the basic tools which will be used through all the article: locally trivial $\mathbb{A}^1$-bundles with additive group actions and equivariant affine birational morphisms between these. In section two, we study $\mathbb{G}_a$-extensions of Type I. The last section is devoted to the classification of quasi-projective $\mathbb{G}_a$-extensions of Type II.

1. Preliminaries

**Notation** 1.1. In the rest of the article, the term *surface* refers to a normal separated 2-dimensional scheme essentially of finite type over a field $k$ of characteristic zero. A *punctured surface* $S_* = S \setminus \{o\}$ is the complement of a closed point $o$ contained in the smooth locus of a surface $S$. We denote by $\kappa$ the residue field of $S$ at $o$.

**Remark** 1.2. We do not require that the residue field $\kappa$ of $S$ at $o$ is an algebraic extension of $k$. For instance, $S$ can very well be the spectrum of the local ring $\mathcal{O}_{X, Z}$ of an arbitrary smooth $k$-variety $X$ at an irreducible closed subvariety $Z$ of codimension two in $X$ and $o$ its unique closed point, in which case the residue field $\kappa$ is isomorphic to the field of rational functions on $Z$.

In this section, we first review basic geometric properties of equivariant extensions of $G_a$-torsors over punctured surfaces. We then collect various technical results on additive group actions on affine-linear bundles of rank one and their behavior under equivariant affine modifications.

**1.1. Equivariant extensions of $G_a$-torsors.** A $G_a$-torsor over punctured surface $S_* = S \setminus \{o\}$ is an $S_*$-scheme $\rho : P \to S_*$ equipped with a $G_a$-action $\mu : G_a \times S_* P \to P$ for which there exists a Zariski open cover $f : Y \to S_*$ of $S_*$ such that $P \times_{S_*} Y$ is equivariantly isomorphic to $G_a Y$ acting on itself by translations. In the present article, we primarily focus on $G_a$-torsors $\rho : P \to S_*$ whose restrictions $P \times_{S_*} U \to U \setminus \{o\}$ over every Zariski open neighborhood $U$ of $o$ in $S$ are nontrivial. Since in this case the total space of $P$ is affine over $S$ (see e.g. [4, Proposition 1.2] whose proof carries over verbatim to our more general situation), it follows that for every $G_a$-extension $j : P \to X$ the fiber $\pi^{-1}(o) \subset X$ of the surjective morphism $\pi : X \to S$ has pure codimension one in $X$. Two important families of examples of non trivial normal $G_a$-extensions $j : SL_2 \to X$ of the $G_a$-torsor $\rho : SL_2 \to SL_2/G_a \simeq \mathbb{A}^2 \setminus \{(0, 0)\}$, where $G_a$ acts on $SL_2$ via left multiplication by upper triangular unipotent matrices, were constructed in [10, Section 5 and 6]. Various other extensions were obtained from these by performing suitable equivariant affine modifications. One can observe that for all these extensions, the fiber $\pi^{-1}(\{(0, 0)\})$ is an $\mathbb{A}^1$-ruled surface, a property which is a consequence of the following more general fact:

**Proposition 1.3.** Let $\rho : P \to S_*$ be a non trivial $G_a$-torsor over the punctured spectrum $S \setminus \{o\}$ of a regular local ring of dimension 2 over an algebraically closed field $k$ and with residue field $k(o) = k$, and let $\pi : X \to S$ be a $G_a$-extension of $P$. If $X$ is smooth along $\pi^{-1}(o)$, then every irreducible component $F$ of $\pi^{-1}(o)_{\text{red}}$ is a uniruled surface. Furthermore, if $X$ is affine then $F$ is an $\mathbb{A}^1$-uniruled, hence $\mathbb{A}^1$-ruled when it is normal.

**Proof.** Since $\pi^{-1}(o)$ has pure codimension one in $X$ and is smooth along $\pi^{-1}(o)$, every irreducible component of $\pi^{-1}(o)$ is a $G_a$-invariant Cartier divisor on $X$. The complement $X'$ of $X$ in $X$ of all but one irreducible component of $\pi^{-1}(o)$ is thus again a $G_a$-extension of $P$, and we may therefore assume without loss of generality that $F = \pi^{-1}(o)_{\text{red}}$ is irreducible. Let $x \in F$ be a closed point in the regular locus of $F$. Since $F$ and $X$ are smooth at $x$ and $X$ is connected, there exists a curve $C \subset X$, smooth at $x$ and intersecting $F$ transversally at $x$. The image $\pi(C)$ of $C$ is a curve on $S$ passing through $o$, and the closure $B$ of $\pi^{-1}(\pi(C) \cap S_*)$ in $X$ is a surface containing $C$. Since $\rho : P \to S_*$ is a $G_a$-torsor, the restriction of $\pi$ to $B \cap P$ is a trivial $G_a$-torsor over the affine curve $\pi(C)$. So $\pi|_B : B \to \pi(C)$ is an $\mathbb{A}^1$-fibration.

Let $\nu : \tilde{C} \to \pi(C)$ be the normalization of $\pi(C)$. Then $\pi|_B$ lifts to an $\mathbb{A}^1$-fibration $\theta : \tilde{B} \to \tilde{C}$ on the normalization $\tilde{B}$ of $B$. The fiber of $\theta$ over every point in $\nu^{-1}(o)$ is a union of rational curves. Since the normalization morphism $\mu : \tilde{B} \to B$ is surjective, one of the irreducible components of $\nu^{-1}(o)$ is mapped by $\mu$ onto a rational curve in $F$ passing through $x$. This shows that for every smooth closed point $x$ of $F$, there exists a non constant rational map $h : \mathbb{P}^1 \dashrightarrow F$ such that $x \in h(\mathbb{P}^1)$. Thus $F$ is uniruled. If $X$ is in addition affine, then $B$ and $\tilde{B}$ are affine surfaces, and the fibers of the $\mathbb{A}^1$-fibration $\theta : B \to \tilde{C}$ consist of disjoint union of curves isomorphic to $\mathbb{A}^1$ when equipped with their reduced structure. This implies that $F$ is not only uniruled but actually $\mathbb{A}^1$-uniruled. □
Example 1.4. Let $X$ be the smooth affine threefold in $\mathbb{A}^2 \times \mathbb{A}^4 = \text{Spec}(k[x,y][c,d,e,f])$ defined by the equations

$$\begin{align*}
xd - y(c + 1) &= 0 \\
x^2 - y^2e &= 0 \\
yf - c(c + 1) &= 0 \\
x^2f - (c + 1)^2e &= 0 \\
de - cf &= 0
\end{align*}$$

equipped with the $G_a$-action induced by the locally nilpotent $k[x,y]$-derivation

$$xy\partial_y + y^2\partial_x + x(2c + 1)\partial_f + (2x^2f - 2xye)\partial_e$$

of its coordinate ring. The morphism $j : SL_2 = \{xv - yu = 1\} \to X$ defined by $(x,y,u,v) \mapsto (x,y,yu,yv,xu^2,xuv)$ is an open embedding of $SL_2$ in $X$ as the complement of the fiber over $o = (0,0)$ of the projection $\pi = pr_{x,y} : X \to \mathbb{A}^2$. So $j : SL_2 \to X$ is an affine $G_a$-extension of the $G_a$-torsor $\rho : SL_2 \to SL_2/G_a = \mathbb{A}^2 \setminus \{0\}$, for which $\pi^{-1}(0)$ consists of the disjoint union of two copies $D_1 = \{x = y = c = 0\} \simeq \text{Spec}(k[d,f])$ and $D_2 = \{x = y = c + 1 = 0\} \simeq \text{Spec}(k[d,e])$ of $\mathbb{A}^2$. Note that the induced $G_a$-action on each of these is the trivial one.

Example 1.5. Let $X$ be the affine $G_a$-extension constructed in the previous example and let $C \subset D_1$ be any smooth affine curve. Let $\tau : \hat{X} \to X$ be the blow-up of $X$ along $C$, let $i : X' \to \hat{X}$ be the open immersion of the complement of the proper transform of $D_1 \cup D_2$ in $\hat{X}$ and let $\pi' = \pi \circ \tau \circ i : X' \to \mathbb{A}^2$. Since $C$ and $D_1 \cup D_2$ are $G_a$-invariant, the $G_a$-action on $X$ lifts to a $G_a$-action on $X'$ which restricts in turn to $X'$. By construction, $\pi'$ is surjective, with fiber $\pi'^{-1}(0)$ isomorphic to $C \times \mathbb{A}^1$ and $\tau \circ i : X' \to X$ restricts to an equivariant isomorphism between $X' \setminus \pi'^{-1}(0)$ and $X \setminus \pi^{-1}(0) \simeq SL_2$. So $\pi' : X' \to \mathbb{A}^2$ is an $G_a$-extension of the $G_a$-torsor $\rho : SL_2 \to SL_2/G_a = \mathbb{A}^2 \setminus \{0\}$.

1.2. Recollection on affine-linear bundles. Affine-linear bundles of rank one over a scheme are natural generalizations of $G_a$-torsors. To fix the notation, we briefly recall their basic definitions and properties.

By a line bundle on a scheme $S$, we mean the relative spectrum $\rho : M = \text{Spec}(\text{Sym} \ M^\vee) \to S$ of the symmetric algebra of the dual of an invertible sheaf of $\mathcal{O}_S$-module $M$. Such a line bundle $M$ can be viewed as a locally constant group scheme over $S$ for the group law $m : M \times_S M \to M$ whose co-morphism

$$m^\sharp : \text{Sym} \ M^\vee \to \text{Sym} \ M^\vee \otimes \text{Sym} \ M^\vee \simeq \text{Sym} \ (M^\vee \otimes M^\vee)$$

is induced by the diagonal homomorphism $M^\vee \to M^\vee \otimes M^\vee$. An $M$-torsor is then an $S$-scheme $\theta : W \to S$ equipped with an action $\mu : M \times_S W \to W$ which is Zariski locally over $S$ isomorphic to $M$ acting on itself by translations.

This is the case precisely when there exists a Zariski open cover $f : Y \to S$ and an $\mathcal{O}_Y$-algebra isomorphism $\psi : f^* \mathcal{A} \to \text{Sym} f^* \mathcal{M}^\vee$ such that over $Y' = Y \times_S Y$ the automorphism $p_1^\sharp \psi \circ p_2^\sharp \psi^{-1} : \text{Sym} \ M_{Y'}^\vee \to \text{Sym} \ M_{Y'}^\vee$ of the symmetric algebra of $M_{Y'}^\vee = p_2^\sharp f^* \mathcal{M}^\vee = p_1^\sharp f^* \mathcal{M}^\vee$ is affine-linear, i.e. induced by an $\mathcal{O}_{Y'}$-module homomorphism $M_{Y'}^\vee \to \text{Sym} \ M_{Y'}^\vee$, of the form

$$\beta \oplus 1 : M_{Y'}^\vee \to \mathcal{O}_{Y'} \otimes M_{Y'}^\vee \to \bigoplus_{n \geq 0} (M_{Y'}^\vee)^{\otimes n} = \text{Sym} \ M_{Y'}^\vee,$$  

for some $\beta \in \text{Hom}_{Y'}(M_{Y'}^\vee, \mathcal{O}_{Y'}) \simeq H^0(Y', M_{Y'}^\vee)$ which is a Čech 1-cocycle with values in $\mathcal{M}$ for the Zariski open cover $f : Y \to S$. Standard arguments show that the isomorphism class of $\theta : W \to S$ depends only on the class of $\beta$ in the Čech cohomology group $H^1(S, \mathcal{M})$, and one eventually gets a one-to-one correspondence between isomorphism classes of $M$-torsors over $S$ and elements of the cohomology group $H^1(S, \mathcal{M}) \simeq \tilde{H}^1(S, \mathcal{M})$ with zero element corresponding to the trivial torsor $\rho : M \to S$.

It is classical that every locally trivial $\mathbb{A}^1$-bundle $\theta : W \to S$ over a reduced scheme $S$ can be equipped with the additional structure of a torsor under a uniquely determined line bundle $M$ on $S$. The existence of this additional structure will be frequently used in the sequel, and we now quickly review its construction (see also e.g. [2, § 2.3 and § 2.4]). Letting $\mathcal{A} = \theta_* \mathcal{O}_W$, there exists by definition a Zariski open cover $f : Y \to S$ and a quasi-coherent $\mathcal{O}_Y$-algebra isomorphism $\varphi : f^* \mathcal{A} \to \mathcal{O}_Y[u]$. Over $Y' = Y \times_S Y$ equipped with the two projections $p_1$ and $p_2$ to $Y$, the $\mathcal{O}_{Y'}$-algebra isomorphism $\Phi = p_1^\sharp \varphi \circ p_2^\sharp \varphi^{-1}$ has the form

$$\Phi : \mathcal{O}_{Y'}[u] \to \mathcal{O}_{Y'}[u], \ u \mapsto au + b$$
for some $a \in \Gamma(Y', \mathcal{O}_{Y'}^*)$ and $b \in \Gamma(Y', \mathcal{O}_{Y'}^*)$ whose pull back over $Y'' = Y \times_S Y \times_S Y$ by the three projections $\pi_{12}, \pi_{23}, \pi_{13} : Y'' \to Y'$ satisfy the cocycle relations $p_{13}^*a = p_{23}^*a \cdot p_{12}^*a$ and $p_{13}^*b = p_{23}^*a \cdot p_{12}^*b$ in $\Gamma(Y'', \mathcal{O}_{Y''}^*)$ and $\Gamma(Y'', \mathcal{O}_{Y''}^*)$ respectively. The first one says that $a$ is a Čech 1-cocycle with values in $\mathcal{O}_S$ for the cover $f : Y \to S$, which thus determines, via the isomorphism $H^1(S, \mathcal{O}_S^*) \cong \text{Pic}(S)$, a unique invertible sheaf on $S$ together with the $\mathcal{O}_Y$-module isomorphism $\alpha : f^*\mathcal{M}^\vee \to \mathcal{O}_Y$ such that $p_1^*a \circ p_2a = \mathcal{O}_Y \to \mathcal{O}_Y$, is the multiplication by $a$. The second one can be equivalently reinterpreted as the fact that $\beta = p_2^*(\alpha)(b) \in \Gamma(Y', \mathcal{O}_{Y'}^*)$ is a Čech 1-cocycle with values in $\mathcal{O}_Y$ for the Zariski open cover $f : Y \to S$. Letting $\text{Sym}(\alpha) : \text{Sym} f^*\mathcal{M}^\vee \to \mathcal{O}_Y[u]$ be the graded $\mathcal{O}_Y$-algebra isomorphism induced by $\alpha$, the isomorphism $\psi = \text{Sym}(\alpha)^{-1} \circ \phi : f^*\mathcal{A} \to \text{Sym} f^*\mathcal{M}^\vee$ has the property that $p_1^*\psi \circ p_2^*\psi^{-1}$ is affine-linear, induced by the homomorphism $\phi \circ \text{id} : \mathcal{M}^\vee \to \mathcal{O}_Y \oplus \mathcal{M}^\vee$. So $\theta : W \to S$ is a torsor under the line bundle $M = \text{Spec}(\text{Sym} \mathcal{M}^\vee)$, with isomorphism class in $H^1(S, \mathcal{O}_S)$ equal to the cohomology class of the cocycle $\beta$. Summing up, we obtain:

**Proposition 1.6.** Let $\theta : W \to S$ be a locally trivial $\mathbb{A}^1$-bundle. Then there exists a unique pair $(M, g)$ consisting of a line bundle $M$ on $S$ and a class $g \in H^1(S, \mathcal{M})$ such that $\theta : W \to S$ is an $M$-torsor with isomorphism class $g$.

1.3. Additive group actions on affine-linear bundles of rank one. Given a locally trivial $\mathbb{A}^1$-bundle $\theta : W \to S$, which we view as an $M$-torsor for a line bundle $M = \text{Spec}(\text{Sym} \mathcal{M}^\vee)$ on $S$, with corresponding action $\mu : M \times_S W \to W$, every nonzero group scheme homomorphism $\xi : \mathbb{G}_{a, S} \to M$ induces a nontrivial $\mathbb{G}_{a, S}$-action $\nu : \mathbb{G}_{a, S} \times_S W \to W$ on $W$. A nonzero group scheme homomorphism $\xi : \mathbb{G}_{a, S} \to \text{Spec}(\mathcal{O}_S[t]) \to M = \text{Spec}(\text{Sym} \mathcal{M}^\vee)$ is uniquely determined by a nonzero $\mathcal{O}_S$-module homomorphism $\mathcal{M}^\vee \to \mathcal{O}_S$, equivalently by a nonzero global section $s \in \Gamma(S, \mathcal{M})$. The following proposition asserts conversely that every nontrivial $\mathbb{G}_{a, S}$-action on an $M$-torsor $\theta : W \to S$ uniquely arises from such a section.

**Proposition 1.7.** ([1, Chapter 3]) Let $\theta : W \to S$ be a torsor under the action $\mu : M \times_S W \to W$ of a line bundle $M = \text{Spec}(\text{Sym} \mathcal{M}^\vee)$ on $S$ and let $\nu : \mathbb{G}_{a, S} \times_S W \to W$ be a non trivial $\mathbb{G}_{a, S}$-action on $W$. Then there exists a non zero global section $s \in \Gamma(S, \mathcal{M})$ such that $\nu = \mu \circ (\xi \times \text{id})$ where $\xi : \mathbb{G}_{a, S} \to M$ is the group scheme homomorphism induced by $s$.

**Proof.** Let $\mathcal{A} = \theta_*\mathcal{O}_W$ and let $f : Y \to S$ be a Zariski open cover such that there exists an $\mathcal{O}_Y$-algebra isomorphism $\phi : f^*\mathcal{A} \to \mathcal{O}_Y[u]$, and let

$$\Phi = p_1^*\phi \circ p_2^*\phi^{-1} : \mathcal{O}_Y[u] \to \mathcal{O}_Y[u], \quad u \mapsto au + b$$

be as in (1.2) above. Since $\theta : W \to S$ is an $M$-torsor, $\phi$ also determines an $\mathcal{O}_Y$-module isomorphism $\alpha : f^*\mathcal{M}^\vee \to \mathcal{O}_Y$ such that $p_1^*\alpha \circ p_2^*\alpha^{-1} : \mathcal{O}_Y \to \mathcal{O}_Y$ is the multiplication by $a$. The $\mathbb{G}_{a, S}$-action $\nu$ on $W$ pulls back to a $\mathbb{G}_{a, Y}$-action $\nu \times \text{id}$ on $W \times_S Y$. The co-morphism $\eta : \mathcal{O}_Y[u] \to \mathcal{O}_Y[u] \otimes \mathcal{O}_Y[t]$ of the nontrivial $\mathbb{G}_{a, Y}$-action $\varphi \circ (\nu \times \text{id}) \circ (\text{id} \times \varphi^{-1})$ on $\text{Spec}(\mathcal{O}_Y[u])$ has the form $u \mapsto u \otimes 1 + 1 \otimes t$ for some nonzero $\gamma \in \Gamma(Y, \mathcal{O}_Y)$. Letting $\mathcal{I} = \gamma : \mathcal{O}_Y \to \mathcal{O}_Y$ be the ideal sheaf generated by $\gamma$, $\eta$ factors as

$$\eta = (\text{id} \otimes j) \circ \tilde{\eta} : \mathcal{O}_Y[u] \to \mathcal{O}_Y[u] \otimes \text{Sym} \mathcal{I} \to \mathcal{O}_Y[u] \otimes \mathcal{O}_Y[t]$$

where $\tilde{\eta}$ is the co-morphism of an action of the line bundle $\text{Spec}(\text{Sym} \mathcal{I}) \to Y$ on $A^1 \times_S Y \simeq W \times_S Y$ and $j : \text{Sym} \mathcal{I} \to \mathcal{O}_Y[t]$ is the homomorphism induced by the inclusion $\mathcal{I} \subset \mathcal{O}_Y$. Pulling back to $Y'$, we find that $p_2^*\gamma = a \cdot p_1^*\gamma$, which implies that $\gamma(\xi) \in \Gamma(Y, f^*\mathcal{M})$ is the pull-back $f^*$s to $Y$ of a nonzero global section $s \in \Gamma(S, \mathcal{M})$. Letting $D = \text{div}_0(s)$ be the divisors of zeros of $s$, we have $\mathcal{M}^\vee \simeq \mathcal{O}_S(-D) \subset \mathcal{O}_S$ and $f^*\mathcal{M}^\vee \simeq \mathcal{O}_Y(-f^*D) \subset \mathcal{O}_Y$ is equal to the ideal $\mathcal{I} = \gamma : \mathcal{O}_Y$. The global section $f^*s$ viewed as a homomorphism $f^*\mathcal{M}^\vee \to \mathcal{O}_Y$ coincides via these isomorphisms with the inclusion $\gamma : \mathcal{O}_Y \to \mathcal{O}_Y$. We can thus rewrite $\eta$ in the form

$$\eta = (\text{id} \otimes \text{Sym} f^*s) \circ \tilde{\eta} : \mathcal{O}_Y[u] \to \mathcal{O}_Y[u] \otimes \text{Sym} f^*\mathcal{M}^\vee \to \mathcal{O}_Y[u] \otimes \mathcal{O}_Y[t].$$

By construction $\tilde{\eta} = (\varphi \otimes \text{id}) \circ f^*\mu^d \circ \varphi^{-1}$ where $f^*\mu^d$ is the pull-back of the co-morphism $\mu^d : \mathcal{A} \to \mathcal{A} \otimes \text{Sym} f^*\mathcal{M}^\vee$ of the action $\mu : M \times_S W \to W$ of $M$ on $W$. It follows that the pull-back $f^*\nu^d$ of the co-morphism of the action $\nu : \mathbb{G}_{a, S} \times W \to W$ factors as

$$f^*\nu^d = (\text{id} \otimes \text{Sym} f^*s) \circ f^*\mu^d = f^*\mathcal{A} \to f^*\mathcal{A} \otimes \text{Sym} f^*\mathcal{M}^\vee \to f^*\mathcal{A} \otimes \mathcal{O}_Y[t]$$

This in turn implies that $\nu^d$ factors as $(\text{id} \otimes \text{Sym} s) \circ \mu^d : \mathcal{A} \to \mathcal{A} \otimes \text{Sym} \mathcal{M}^\vee \to \mathcal{A} \otimes \mathcal{O}_Y[t]$ as desired. □
EQUIVARIANT EXTENSIONS OF $G_a$-TORSORS OVER PUNCTURED SURFACES

Remark 1.8. In the setting of Proposition 1.7, let $U \subset S$ be the complement of the zero locus of $s$, the morphism $\xi$ restricts to an isomorphism of group schemes $\xi|_U : G_{a,U} \to M|_U$ for which $W|_U$ equipped with the $G_{a,U}$-action $\nu|_U : G_{a,U} \times_U W|_U \to W|_U$ is a $G_{a,U}$-torus. This isomorphism class in $H^1(U, O_U)$ of this $G_{a,U}$-torus coincides with the image of the isomorphism class $g \in H^1(S, M)$ of $W$ by the composition of the restriction homomorphism $\text{res} : H^1(S, M) \to H^1(U, M|_U)$ with the inverse of the isomorphism $H^1(U, O_U) \to H^1(U, M|_U)$ induced by $s|_U$.

1.4. $G_{a}$-equivariant affine modifications of affine-linear bundles of rank one. Recall [3] that given an integral scheme $X$ with sheaf of rational functions $K_X$, an effective Cartier divisor $D$ on $X$ and a closed subscheme $Z \subset X$ whose ideal sheaf $I \subset O_X$ contains $O_X(-D)$, the affine modification of $X$ with center $(I,D)$ is the affine $X$-scheme $\sigma : X' = \text{Spec}(O_X[I/D]) \to X$ where $O_X[I/D]$ denotes the quotient of the Rees algebra

$$O_X[(I \otimes O_X(D))] = \bigoplus_{n \geq 0} (I \otimes O_X(D))^n t^n \subset K_X[t]$$

of the fractional ideal $I \otimes O_X(D) \subset K_X$ by the ideal generated by $1 - t$. In the case where $X = \text{Spec}(A)$ is affine, $D = \text{div}(f)$ is principal and $Z$ is defined by an ideal $I \subset A$ containing $f$ then $X'$ is isomorphic to the affine modification $X' = \text{Spec}(A[I/f])$ of $X$ with center $(I,f)$ in the sense of [11].

Now let $S$ be an integral scheme and let $\theta : W \to S$ be a locally trivial $A^1$-bundle. Let $C \subset S$ be an integral Cartier divisor, let $D = \theta^{-1}(C)$ be its inverse image in $W$ and let $Z \subset D$ be a non empty integral closed subscheme of $D$ on which $\theta$ restricts to an open embedding $\theta|_Z : Z \to C$. Equivalently, $Z$ is the closure in $D$ of the image of $\alpha(U)$ of a rational section $\alpha : C \to D$ of the locally trivial $A^1$-bundle $\theta|_D : D \to C$ defined over a non empty open subset $U$ of $C$. The complement $F$ of $\theta|_Z(Z)$ in $C$ is a closed subset of $C$ hence of $S$. Letting $i : S \setminus F \hookrightarrow S$ be the natural open embedding, we have the following result:

Lemma 1.9. Let $\sigma : W' \to W$ be the affine modification of $W$ with center $(I_Z, D)$. Then the composition $\theta \circ \sigma : W' \to S$ factors through a locally trivial $A^1$-bundle $\theta' : W' \to S \setminus F$ in such a way that we have a cartesian diagram

$$\begin{align*}
W' & \xrightarrow{\sigma} W \\
\theta' & \downarrow \quad \theta \\
S \setminus F & \xrightarrow{i} S.
\end{align*}$$

Proof. The question being local with respect to a Zariski open cover of $S$ over which $\theta : W \to S$ becomes trivial, we can assume without loss of generality that $S = \text{Spec}(A), W = \text{Spec}(A[x]), C = \text{div}(f)$ for some non zero element $f \in A$. The integral closed subscheme $Z \subset D$ is then defined by an ideal $I$ of the form $(f,g)$ where $g(x) \in A[x]$ is an element whose image in $(A[f])[x]$ is a polynomial of degree one in $t$. So $g(x) = a_0 + a_1 x + x^2 f R(x)$ where $a_0 \in A, a_1 \in A$ has non zero residue class in $A/f$ and $R(x) \in A[x]$. The condition that $\theta|_Z : Z \to C$ is an open embedding implies further that the residue classes $\overline{a}_0$ and $\overline{a}_1$ of $a_0$ and $a_1$ in $A/f$ generate the unit ideal. The complement $F$ of the image of $\theta|_Z(Z)$ in $C$ is then equal to the closed subscheme of $C$ with defining ideal $(\overline{a}_1) \subset A/f$, hence to the closed subscheme of $S$ with defining ideal $(f,a_1) \subset A$. The algebra $A[t]/I/f]$ is isomorphic to

$$A[x][u]/(g - fu) = A[x][u - x^2 f R(x)]/(a_0 + a_1 x - f(u - t^2 R(x)) \simeq A[x][v]/(a_0 + a_1 x - f v).$$

One deduces from this presentation that the morphism $\theta \circ \sigma : W' = \text{Spec}(A[I/f]) \to \text{Spec}(A)$ corresponding to the inclusion $A \to A[I/f]$ factors through a locally trivial $A^1$-bundle $\theta' : W' \to S \setminus F$ over the complement of $F$. Namely, since $\overline{a}_0$ and $\overline{a}_1$ generate the unit ideal in $A/f$, it follows that $a_1$ and $f$ generate the unit ideal in $A[x][u]/(g - fu)$. So $W'$ is covered by the two principal affine open subsets

$$W'_{a_1} \simeq \text{Spec}(A_{a_1}[u]/(a_0 + a_1 x - f)) \simeq \text{Spec}(A_{a_1}[v]) \simeq S_{a_1} \times A^1$$

$$W'_{f} \simeq \text{Spec}(A[f][v]/(a_0 + a_1 x - f)) \simeq \text{Spec}(A_{f}[x]) \simeq S_{f} \times A^1$$

on which $\theta'$ restricts to the projection onto the first factor.

With the notation above, $\theta : W \to S$ and $\theta' : W' \to S \setminus F$ are torsors under the action of line bundles $M = \text{Spec}(\text{Sym} \ M^\vee)$ and $M' = \text{Spec}(\text{Sym} \ M'^\vee)$ for certain uniquely determined invertible sheaves $M$ and $M'$ on $S$ and $S \setminus F$ respectively.
Lemma 1.10. ([1], §4.3) Let $\sigma : W' \to W$ be the affine modification of $W$ with center $(I_Z, D)$ as is Lemma 1.9. Then $\mathcal{M}' = \mathcal{M} \otimes_{\mathcal{O}_S} \mathcal{O}_S(-C)|_{S \setminus F}$ and the cartesian diagram of Lemma 1.9 is equivariant for the group scheme homomorphism $\xi : M' \to M$ induced by the homomorphism $\mathcal{M} \otimes_{\mathcal{O}_S} \mathcal{O}_S(-C) \to \mathcal{M}$ obtained by tensoring the inclusion $\mathcal{O}_S(-C) \hookrightarrow \mathcal{O}_S$ by $\mathcal{M}$.

Proof. Since $M$ and $M'$ are uniquely determined, the question is again local with respect to a Zariski open cover of $S$ over which $\theta : W \to S$, hence $M$, becomes trivial. We can thus assume as in the proof of Lemma 1.9 that $S = \text{Spec}(A)$, $W = \text{Spec}(A[x])$, that $C = \text{div}(f)$ for some non zero element $f \in A$ and that $Z \subset D$ is defined by the ideal $(g, f)$ for some $g = a_0 + a_1 x + f x^2 R(x) \in A[x]$. Furthermore, the action of $M \simeq G_a S = \text{Spec}(A[t])$ on $W \simeq S \times A^1$ is the one by translations $x \mapsto x + t$ on the second factor. Let $N = \text{Spec}(\text{Sym} \mathcal{O}_S(C)) \simeq \text{Spec}(\text{Sym} f^{-1} A)$ where $f^{-1} A$ denotes the free sub-$A$-module of the field of fractions Frac$(A)$ of $A$ generated by $f^{-1}$. As in the proof of Proposition 1.7, the inclusion $\mathcal{O}_S(-C) = f \cdot \mathcal{O}_S \hookrightarrow \mathcal{O}_S$ induces a group-scheme homomorphism $\xi : N \to M$ whose co-morphism $\xi^\ast$ coincides with the inclusion $A[t] \subset \text{Sym} f^{-1} A = A[(f^{-1} t)]$. The co-morphism of the corresponding action of $N$ on $W$ is given by

$$A[x] \to A[x] \otimes A[f^{-1} t], \quad x \mapsto x \otimes 1 + 1 \otimes t = x \otimes 1 + f \otimes f^{-1} t.$$ 

This action lifts on $W' \simeq \text{Spec}(A[x][v]/(a_0 + a_1 x - fv))$ to an action $\nu : N \times_S W' \to W'$ whose co-morphism

$$A[x][v]/(a_0 + a_1 x - fv) \to A[x][v]/(a_0 + a_1 x - fv) \otimes A[f^{-1} t]$$

is given by $x \mapsto x \otimes 1 + 1 \otimes t$ and $v \mapsto v \otimes 1 + a_1 \otimes f^{-1} t$. By construction, the principal open subsets $W'_1 \simeq \text{Spec}(A[x][v]/(a_0 + a_1 x))$ and $W'_1 \simeq \text{Spec}(A[x][v]/(a_1 x - fv))$ of $W'$ equipped with the induced actions of $N|_{S_1}$ and $N|_{S_1}$ respectively are equivariantly isomorphic to $N|_{S_1}$ and $N|_{S_1}$ acting on themselves by translations. So $\theta' : W' \to S \setminus F$ is an $N|_{S \setminus F}$-torsor, showing that $\mathcal{M}' = \mathcal{M} \otimes_{\mathcal{O}_S} \mathcal{O}_S(-C)|_{S \setminus F}$ as desired.

2. Extensions of $G_a$-torsors of Type I: locally trivial bundles over the blow-up of a point

Given a surface $S$ and a locally trivial $A^1$-bundle $\theta : W \to \tilde{S}$ over the blow-up $\tau : \tilde{S} \to S$ of a closed point $o$ in the smooth locus of $S$, the restriction of $W$ over the complement $\tilde{S} \setminus E$ of the exceptional divisor $E$ of $\tau$ is a locally trivial $A^1$-bundle $\tau \circ \theta : W |_{\tilde{S} \setminus E} \to \tilde{S} \setminus E \xrightarrow{\sim} S \setminus \{o\}$. This observation combined with the following re-interpretation of an example constructed in [10] suggests that locally trivial $A^1$-bundles over the blow-up of closed point $o$ in the smooth locus of a surface $S$ form a natural class of schemes in which to search for nontrivial $G_a$-extension of $G_a$-bundles over punctured surfaces.

Example 2.1. Let $o = V(x, y)$ be a global scheme-theoretic complete intersection closed point in the smooth locus of a surface $S$. Let $\rho : P \to S \setminus \{o\}$ and $\pi_0 : X_0 \to S$ be the affine $S$-schemes with defining sheaves of ideals $(xv - yu - 1)$ and $(xr - yq, yp - x(q - 1), pr - q(q - 1))$ in $\mathcal{O}_S[u, v]$ and $\mathcal{O}_S[p, q, r]$ respectively. The morphism of $S$-schemes $j_0 : P \to X_0$ defined by $(x, y, u, v) \mapsto ((x, y, xu, xv, yv)$ is an open embedding, equivariant for the $G_a$-actions on $P$ and $X_0$ associated with the locally nilpotent $\mathcal{O}_S$-derivations $x \partial_x + y \partial_y$ and $x^2 \partial_x + xy \partial_y + y^2 \partial_y$ of $\rho_\ast \mathcal{O}_P$ and $(\pi_0)_\ast \mathcal{O}_{X_0}$ respectively. It is straightforward to check that $\rho : P \to S \setminus \{o\}$ is a $G_a$-torsor, and that $\pi_0 : X_0 \to S$ is a $G_a$-extension of $P$ whose fiber over $o$ is isomorphic to the smooth affine quadric $\{pr - q(q - 1) = 0\} \subset A^2$. Viewing the blow-up $\tilde{S}$ of $o$ as the closed subscheme of $S \times_k \text{Proj}(k[u_0, u_1])$ with equation $xu_1 - yu_0 = 0$, the morphism of $S$-schemes $\theta : X_0 \to \tilde{S}$ defined by

$$(x, y, p, q, r) \mapsto ((x, y), [x : y]) = ((x, y), [q : r]) = ((x, y), [p : q - 1])$$

is a locally trivial $A^1$-bundle, actually a torsor under the line bundle corresponding to the invertible sheaf $\mathcal{O}_{\tilde{S}}(-2E)$, where $E \simeq P^1_k$ denotes the exceptional divisor of the blow-up.

Notation 2.2. Given a surface $S$ and a closed point $o$ in the smooth locus of $S$, with residue field $k$, we denote by $\tau : \tilde{S} \to S$ be the blow-up of $o$, with exceptional divisor $E \simeq P^1_k$. We identify $\tilde{S} \setminus E$ and $S \setminus \{o\}$ by the isomorphism induced by $\tau$. For every $\ell \in Z$, we denote by $M(\ell) = \text{Spec}(\text{Sym} \mathcal{O}_{\tilde{S}}(\ell E))$ the line bundle on $\tilde{S}$ corresponding to the invertible sheaf $\mathcal{O}_{\tilde{S}}(\ell E)$.
The aim of this section is to give a classification of all possible $G_a$-equivariant extensions of Type I of a given $G_a$-torsor $\rho : P \to S_*$, that is $G_a$-extensions $\pi : W \to S$ that factor through locally trivial $A^1$-bundles $\theta : W \to \tilde{S}$.

2.1. Existence of $G_a$-extensions of Type I. By virtue of Propositions 1.6 and 1.7, there exists a one-to-one correspondence between $G_a$-equivariant extensions of a $G_a$-torsor $\rho : P \to S_*$ that factor through a locally trivial $A^1$-bundle $\theta : W \to \tilde{S}$ and pairs $(M, \xi)$ consisting of an $M$-torsor $\theta : W \to \tilde{S}$ for some line bundle $M$ on $\tilde{S}$ and a group scheme homomorphism $\xi : G_a,\tilde{S} \to M$ restricting to an isomorphism over $\tilde{S} \setminus E$, such that $W$ equipped with the $G_a,\tilde{S}$-action deduced by composition with $\xi$ restricts on $S_* = \tilde{S} \setminus E$ to a $G_a,\tilde{S}$-torsor $\theta | S_* : W | S_* \to S_*$ isomorphic to $\rho : P \to S_*$. The condition that $\xi : G_a,\tilde{S} \to M$ restricts to an isomorphism outside $E$ implies that $M \cong M(\ell)$ for some $\ell$, which is necessarily non negative, and that $\xi$ is induced by the canonical global section of $O_S(\ell E)$ with divisor $\ell E$.

**Proposition 2.3.** Let $\rho : P \to S_*$ be a $G_a,\tilde{S}$-torsor. Then there exists an integer $\ell_0 \geq 0$ depending on $P$ only such that for every $\ell \geq \ell_0$, $P$ admits a $G_a$-extension to a uniquely determined $M(\ell)$-torsor $\theta_\ell : W(P, \ell) \to \tilde{S}$ equipped with the $G_a,\tilde{S}$-action induced by the canonical global section $s_\ell \in \Gamma(\tilde{S}, O_S(\ell E))$ with divisor $\ell E$.

**Proof.** The invertible sheaves $O_S(nE)$, $n \geq 0$, form an inductive system of sub-$O_S$-modules of the sheaf $\mathcal{K}_S$ of rational function on $\tilde{S}$, for where for each $n$, the injective transition homomorphism $j_{n,n+1} : O_S(nE) \to O_S((n+1)E)$ is obtained by tensoring the canonical section $O_S \to O_S(\ell E)$ with divisor $E$ with $O_S(nE)$. Let $i : S_* = \tilde{S} \setminus E \hookrightarrow \tilde{S}$ be the open inclusion. Since $E$ is a Cartier divisor, it follows from [6, Théorème 9.3.1] that $i_*O_S \simeq \text{colim}_{n \geq 0}O_S(nE)$. Furthermore, since $E \simeq \mathbb{P}_k^1(1)$ is the exceptional divisor of $\tau : \tilde{S} \to S$, we have $O_S(\ell E)|_E \simeq O_{\mathbb{P}_k^1(-1)}$, and the long exact sequence of cohomology for the short exact sequence

\begin{equation}
0 \to O_S(nE) \to O_S((n+1)E) \to O_S((n+1)E)|_E \to 0, \quad n \geq 0,
\end{equation}

combined with the vanishing of $H^0(\mathbb{P}_k^1, O_{\mathbb{P}_k^1}(-n - 1))$ for every $n \geq 0$ implies that the transition homomorphisms

\[H^1(j_{n,n+1}) : H^1(\tilde{S}, O_S(nE)) \to H^1(\tilde{S}, O_S((n+1)E)), \quad n \geq 0,\]

are all injective. By assumption, $S$ whence $\tilde{S}$ is noetherian, and $i : S_* \to \tilde{S}$ is an affine morphism as $E$ is a Cartier divisor on $\tilde{S}$. We thus deduce from [12, Theorem 8] and [7, Corollaire 1.3.3] that the canonical homomorphism

\[\psi : \text{colim}_{n \geq 0} H^1(\tilde{S}, O_S(nE)) \to H^1(S_*, O_{S_*})\]

obtained as the composition of the canonical homomorphisms

\[\text{colim}_{n \geq 0} H^1(\tilde{S}, O_S(nE)) \to H^1(\tilde{S}, \text{colim}_{n \geq 0} O_S(nE)) = H^1(\tilde{S}, i_*O_{S_*})\]

and $H^1(\tilde{S}, i_*O_{S_*}) \to H^1(S_*, O_{S_*})$ is an isomorphism.

Let $g \in H^1(S_*, O_{S_*})$ be the isomorphism class of the $G_a,\tilde{S}$-torsor $\rho : P \to S_*$. If $g = 0$, then since $\psi$ is an isomorphism, we have $\psi^{-1}(g) = 0$ and, since the homomorphisms $H^1(j_{n,n+1})$ are injective, it follows that $\psi^{-1}(g)$ is represented by the zero sequence $(0)_n \in H^1(\tilde{S}, O_S(nE))$, $n \geq 0$. Consequently, the only $G_a$-extensions of $P$ are the line bundles $W(P, \ell) = M(\ell)$, $\ell \geq 0$, each equipped with the $G_a,\tilde{S}$-action induced by its canonical global section $s_\ell \in \Gamma(\tilde{S}, O_S(\ell E))$.

Otherwise, if $g \neq 0$, then $h = \psi^{-1}(g) \neq 0$, and since the homomorphisms $H^1(j_{n,n+1})$, $n \geq 0$ are injective, it follows that there exists a unique minimal integer $\ell_0$ such that $h$ is represented by the sequence

\[h_n = H^1(j_{n-1,n}) \circ \cdots \circ H^1(j_{\ell_0,\ell_0+1})(h_{\ell_0}) \in H^1(\tilde{S}, O_S(nE)), \quad n \geq \ell_0\]

for some non zero $h_{\ell_0} \in H^1(\tilde{S}, O_S(\ell_0 E))$. It then follows from Proposition 1.7 that for every $\ell \geq \ell_0$, the $M(\ell)$-torsor $\theta_\ell : W(P, \ell) \to \tilde{S}$ with isomorphism class $h_\ell$ equipped with the $G_a,\tilde{S}$-action induced by the canonical global section $s_\ell \in \Gamma(\tilde{S}, O_S(\ell E))$ is a $G_a$-extension of $P$.

Conversely, for every $G_a$-extension of $P$ into an $M(\ell)$-torsor $\theta : W \to \tilde{S}$ equipped with the $G_a,\tilde{S}$-action induced by the canonical global section $s_\ell \in \Gamma(\tilde{S}, O_S(\ell E))$, it follows from Proposition 1.7 again that the
image of the isomorphism class \( h\ell \in \text{H}^1(\tilde{S}, \mathcal{O}_{\tilde{S}}(\ell E)) \) of \( W \) in \( \text{H}^1(\tilde{S} \setminus E, \mathcal{O}_{\tilde{S}}(\ell E)|_{\tilde{S} \setminus E}) \simeq \text{H}^1(S_*, \mathcal{O}_{S_*}) \) is equal to \( g \). Letting \( h \in \text{colim}_{n \geq 0} \text{H}^1(\tilde{S}, \mathcal{O}_{\tilde{S}}(nE)) \) be the element represented by the sequence

\[
h_n = (\text{H}^1(j_{n-1, n} \circ \cdots \circ j_{\ell, \ell+1})(h\ell))_{n \geq \ell} \in \text{H}^1(\tilde{S}, \mathcal{O}_{\tilde{S}}(nE)), \quad n \geq \ell
\]

we have \( \psi(h) = g \) and since \( \psi \) is an isomorphism, we conclude that \( W \simeq W(P, \ell) \). \( \square \)

2.2. \( \mathbb{G}_a \)-extensions with affine total spaces. The extensions \( \theta : W \to \tilde{S} \) we get from Proposition 2.3 are not necessarily affine over \( S \). In this subsection we establish a criterion for affineness which we then use to characterize all extensions \( \theta : W \to \tilde{S} \) of a \( \mathbb{G}_a \)-torsor \( \rho : P \to S_* \) whose total spaces \( W \) are affine over \( S \).

**Lemma 2.4.** Let \( S = \text{Spec}(A) \) be an affine surface and let \( o = V(x, y) \) be a global scheme-theoretic complete intersection point in the smooth locus of \( S \). Let \( \tau : \tilde{S} \to S \) be the blow-up of \( o \) with exceptional divisor \( E \) and let \( \theta : W \to \tilde{S} \) be an \( M(\ell) \)-torsor for some \( \ell \geq 0 \). Then the following hold:

a) \( \text{H}^1(W, \mathcal{O}_W) = 0 \).

b) If \( \text{H}^1(W, \theta^* \mathcal{O}_{\tilde{S}}(\ell E)) = 0 \) for some \( \ell \geq 2 \) then \( W \) is an affine scheme.

**Proof.** Since \( o \) is a scheme-theoretic complete intersection, we can identify \( \tilde{S} \) with the closed subvariety of \( S \times_k \mathbb{P}^1_k = S \times_k \text{Proj}(k[t_0, t_1]) \) defined by the equation \( xt_1 - yt_0 = 0 \). The restriction \( p : \tilde{S} \to \mathbb{P}^1_k \) of the projection to the second factor is an affine morphism. More precisely, letting \( U_0 = \mathbb{P}^1_k \setminus \{1 : 0\} \simeq \text{Spec}(k[z]) \) and \( U = \mathbb{P}^1_k \setminus \{0 : 1\} \simeq \text{Spec}(k[z']) \) be the standard affine open cover of \( \mathbb{P}^1_k \), we have \( p^{-1}(U_0) \simeq \text{Spec}(A[z]/(x - yz)) \) and \( p^{-1}(U) \simeq \text{Spec}(A[z']/(y - xz')) \). The exceptional divisor \( E \simeq \mathbb{P}^1_k \) of \( \tilde{S} \to S \) is a flat quasi-section of \( p \) with local equations \( y = 0 \) and \( x = 0 \) in the affine charts \( p^{-1}(U_0) \) and \( p^{-1}(U) \) respectively. Every \( M(\ell) \)-torsor \( \theta : W \to \tilde{S} \) for some \( \ell \geq 0 \) is isomorphic to the scheme obtained by gluing \( W_0 = p^{-1}(U_0) \times \text{Spec}(k[u]) \) with \( W_0 = p^{-1}(U) \times \text{Spec}(k[u']) \) over \( U_0 \cap U \) by an isomorphism induced by a \( k \)-algebra isomorphism of the form

\[
A[z^\pm 1]/(y - xz')/u'] \ni (z', u') \mapsto (z^{-1}, z^\ell u + p) \in A[z^\pm 1]/(x - yz)[u]
\]

for some \( p \in A[z^\pm 1]/(x - yz) \). Since \( \text{H}^1(W, \mathcal{O}_W) \simeq \text{H}^1(W, \mathcal{O}_W) \simeq \text{H}^1(W_0, \mathcal{O}_W) \), it is enough in order to prove a) to check that every Čech 1-cocycle \( g \) with value in \( \mathcal{O}_W \) for the covering of \( W \) by the affine open subsets \( W_0 \) and \( W_0 \) is a coboundary. Viewing \( g \) as an element \( g = g(z^\pm 1, u) \in A[z^\pm 1]/(x - yz)[u] \), it is enough to show that every monomial \( g_m = h z^r u^s \) where \( h \in A, \) \( r, s \in \mathbb{Z} \) and \( s \in \mathbb{Z} \) is a coboundary, which is the case if and only if there exist \( a(z, u) \in A[z]/(f - g z)[u] \) and \( b(z', u') \in A[z']/(y - x z')/u' \) such that \( g = b(z^{-1}, z^\ell u + p) - b(z, u) \). If \( r \geq 0 \) then \( g \in A[z]/(x - yz)[u] \) is a coboundary. We thus assume from now on that \( r > 0 \). Suppose that \( s > 0 \). Then we can write \( u^s = z^{-\ell s}(z^\ell u + p)^s - R(u) \) where \( R \in A[z^\pm 1]/(x - yz)[u] \) is polynomial whose degree in \( u \) is strictly less than \( s \). Then since \( r < 0 \),

\[
h z^r u^s = h z^{-r - \ell s}(z^\ell u + p)^s - h z^r R(u)
\]

\[
= b(z^{-1}, z^\ell u + p) - h z^r R(u)
\]

where \( b(z', u') = b(z')^{-r + \ell s}(u')^s \in A[z']/(y - x z')[u'] \). So \( g_m \) is a coboundary if and only if \( -h z^r R(u) \) is. By induction, we only need to check that every monomial \( g_0 = h z^r \in A[z^\pm 1]/(x - yz)[u] \) of degree 0 in \( u \) is a coboundary. But such a cocycle is simply the pull-back to \( W \) of a Čech 1-cocycle \( h_0 \) with value in \( \mathcal{O}_{\tilde{S}} \) for the covering of \( \tilde{S} \) by the affine open subsets \( p^{-1}(U_0) \) and \( p^{-1}(U) \). Since the canonical homomorphism

\[
\text{H}^1(S, \mathcal{O}_S) = \text{H}^1(S, \theta_* \mathcal{O}_{\tilde{S}}) \to \text{H}^1(\tilde{S}, \mathcal{O}_{\tilde{S}}) \simeq \text{H}^1(p^{-1}(U_0), p^{-1}(U)) \}
\]

is an isomorphism and \( \text{H}^1(S, \mathcal{O}_S) = 0 \) as \( S \) is affine, we conclude that \( h_0 \) is a coboundary, hence that \( g_0 \) is a coboundary too. This proves a).
Now suppose that \( H^1(W, \theta^*\mathcal{O}_S(\ell(E))) = 0 \) for some \( \ell \geq 2 \). Let \( \eta : V \to \mathbb{P}^1_k \) be a non trivial \( \mathcal{O}_{\mathbb{P}^1_k}(-\ell) \)-torsor and consider the fiber product \( W \times_{\mathbb{P}^1_k, \eta} V \):

\[
\begin{array}{ccc}
W & \xleftarrow{\text{pr}} & \mathbb{P}^1_k \\
\downarrow & & \downarrow \\
W \times_{\mathbb{P}^1_k, \eta} V & \to & V
\end{array}
\]

By virtue of [5, Proposition 3.1], \( V \) is an affine surface. Since \( p \circ \theta : W \to \mathbb{P}^1_k \) is an affine morphism, so is \( \text{pr}_V : W \times_{\mathbb{P}^1_k} V \to V \) and hence, \( W \times_{\mathbb{P}^1_k} V \) is an affine scheme. On the other hand, since \( p^*\mathcal{O}_{\mathbb{P}^1_k}(-1) \simeq \mathcal{O}_S(\ell(E)) \), the projection \( \text{pr}_W : W \times_{\mathbb{P}^1_k} V \to W \) is a \( \theta^*M(\ell) \)-torsor, hence is isomorphic to the trivial one \( q : \theta^*M(\ell) \to W \) by hypothesis. So \( W \) is isomorphic to the zero section of \( \theta^*M(\ell) \), which is a closed subscheme of the affine scheme \( W \times_{\mathbb{P}^1_k} V \), hence an affine scheme.

We are now ready to prove the following characterization:

**Theorem 2.5.** A \( \mathbb{G}_{a,S^*} \)-torsor \( \rho : P \to S^* \) admits a \( \mathbb{G}_a \)-extension to a locally trivial \( \mathbb{A}^1 \)-bundle whose total space is affine over \( S \) if and only if for every Zariski open neighborhood \( U \) of \( o \), \( P \times_{S^*} U \to U_* = U \setminus \{ o \} \) is a non trivial \( \mathbb{G}_{a,U_*} \)-torsor.

When it exists, the corresponding locally trivial \( \mathbb{A}^1 \)-bundle \( \theta : W \to \tilde{S} \) is unique and is an \( M(\ell_0) \)-torsor for some \( \ell_0 \geq 2 \), whose restriction to \( E \simeq \mathbb{P}^1_k \) is a non trivial \( \mathcal{O}_{\mathbb{P}^1_k}(-\ell_0) \)-torsor.

**Proof.** The scheme \( W \) is affine over \( S \) if and only if its restriction \( W|_E \) over \( E \subset \tilde{S} \) is a nontrivial torsor. Indeed, if \( W|_E \) is a trivial torsor then it is a line bundle over \( E \simeq \mathbb{P}^1_k \). Its zero section is then a proper curve contained in the fiber of \( \pi = \tau \circ \theta : W \to S \), which prevents \( \pi \) from being an affine morphism. Conversely, if \( W|_E \) is nontrivial, then it is a torsor under a uniquely determined line bundle \( \mathcal{O}_{\mathbb{P}^1_k}(-m) \) for some \( m \geq 2 \) necessarily. Since by construction \( \pi \) restricts over \( S^* \) to \( \rho : P \to S^* \) which is an affine morphism, \( \pi \) is affine if and only if there exists an open neighborhood \( U \) of \( o \) in \( S \) such that \( \pi^{-1}(U) \) is affine. Replacing \( S \) by a suitable affine open neighborhood of \( o \), we can therefore assume without loss of generality that \( S = \text{Spec}(A) \) is affine and that \( o \) is a scheme-theoretic complete intersection \( o = V(x, y) \) for some elements \( x, y \in A \). By virtue of [5, Proposition 3.1] every nontrivial \( \mathcal{O}_{\mathbb{P}^1_k}(-m) \)-torsor, \( m \geq 2 \), has affine total space. The Cartier divisor \( D = W|_E \) in \( W \) is thus an affine surface, and so \( H^1(D, \mathcal{O}_W((n+1)D)|_D) = 0 \) for every \( n \in \mathbb{Z} \). By a) in Lemma 2.4, \( H^1(W, \mathcal{O}_W) = 0 \), and we deduce successively from the long exact sequence of cohomology for the short exact sequence

\[
0 \to \mathcal{O}_W(nD) \to \mathcal{O}_W((n+1)D) \to \mathcal{O}_W((n+1)D)|_D \to 0
\]

in the case \( n = 0 \) and then \( n = 1 \) that \( H^1(W, \theta^*\mathcal{O}_S(D)) = H^1(W, \mathcal{O}_W(2D)) = 0 \). Since \( \mathcal{O}_W(2D) \simeq \theta^*\mathcal{O}_S(2E) \), we conclude from b) in the same lemma that \( W \) is affine.

The condition that \( P \times_{S^*} U \to U_* \) is nontrivial for every open neighborhood \( U \) of \( o \) is necessary for the existence of an extension \( \theta : W \to \tilde{S} \) of \( P \) for which \( W|_E \) is a nontrivial torsor. Indeed, if there exists a Zariski open neighborhood \( U \) of \( o \) such that the restriction of \( P \) over \( U_* \) is the trivial \( \mathbb{G}_{a,U_*} \)-torsor, then the image in \( H^1(U_*, \mathcal{O}_{U_*}) \) of the isomorphism class \( g \) of \( P \) is zero and so, arguing as in the proof of Proposition 2.3, every \( \mathbb{G}_{a,U_*} \)-extension \( \theta : W \to \tilde{S} \) restricts on \( \tau^{-1}(U) \) to the trivial \( M(\ell_0) \)-torsor \( M(\ell_0)|_{\tau^{-1}(U)} \to \tau^{-1}(U) \), hence a trivial torsor on \( E \subset \tau^{-1}(U) \).

Now suppose that \( P : P \to S^* \) is a \( \mathbb{G}_{a,S^*} \)-torsor with isomorphism class \( g \in H^1(S^*, \mathcal{O}_{S^*}) \) such that \( P \times_{S^*} U \to U_* \) is non trivial for every open neighborhood \( U \) of \( o \). The inverse image \( h = \psi^{-1}(g) \in \text{colim}_{n \geq 0} H^1(\tilde{S}, \mathcal{O}_S(nE)) \) of \( g \) by the isomorphism (2.2) is represented by a sequence of nonzero elements \( h_n \in H^1(\tilde{S}, \mathcal{O}_S(nE)) \) as in (2.3) above. By the long exact sequence of cohomology of the short exact sequence (2.1), the image \( \overline{h}_n \) of \( h_n \) in \( H^1(E, \mathcal{O}_S(nE)|_E) \simeq H^1(\mathbb{P}^1_k, \mathcal{O}_{\mathbb{P}^1_k}(-n)) \) is nonzero if and only if \( h_n \) is not in the image of the injective homomorphism \( H^1(E, \mathcal{O}_S(nE)) \to \text{colim}_{n \geq 0} H^1(\tilde{S}, \mathcal{O}_S(nE)) \). Since \( \overline{h}_n \) coincides with the isomorphism class of the restriction \( W|_E \) of an \( M(n) \)-torsor \( \theta_n : W_n \to \tilde{S} \) with isomorphism class \( h_n \), we conclude...
that there exists a unique $\ell_0 \geq 2$ such that the restriction to $E$ of an $M(\ell_0)$-torsor $\theta_{t_0} : W_{t_0} \rightarrow \tilde{S}$ with isomorphism class $h_{t_0} \in H^1(S, \mathcal{O}_S(-\ell_0))$ is a nontrivial $\mathcal{O}_{P^1}(\ell_0)$-torsor.

2.3. Examples. In this subsection, we consider $\mathbb{G}_a$-torsors of the punctured affine plane. So $S = \mathbb{A}^2 = \text{Spec}(k[x, y]), \sigma = (0, 0)$ and $A_2 = \mathbb{A}^2 \setminus \{0\}$. We let $\tau : \mathbb{A}^2 \rightarrow \mathbb{A}^2$ be the blow-up of $\sigma$, with exceptional divisor $E \simeq \mathbb{P}^1$ and we let $i : \mathbb{A}^2 \rightarrow \mathbb{A}^2$ be the immersion of $A_2$ as the open subset $\mathbb{A}^2 \setminus E$. We further identify $\mathbb{A}^2$ with the total space $f : \mathbb{A}^2 \rightarrow \mathbb{P}^1$ of the line bundle $\mathcal{O}_{P^1}(-1)$ in such a way that $E$ corresponds to the zero section of this line bundle.

2.3.1. A simple case: homogeneous $\mathbb{G}_a$-torsors. Following [4, §1.3], we say that a non trivial $\mathbb{G}_a,\mathbb{A}^2$-torsor $\rho : P \rightarrow \mathbb{A}^2$ is homogeneous if it admits a lift of the $\mathbb{G}_m$-action $\lambda : (x, y) = (\lambda x, \lambda y)$ on $\mathbb{A}^2$ which is locally linear on the fibers of $\rho$. By [4, Proposition 1.6], this is the case if and only if the isomorphism class $g$ of $P$ in $H^1(\mathbb{A}_2^2, \mathcal{O}_{\mathbb{A}^2})$ can be represented on the open covering of $\mathbb{A}^2_2$ by the principal open subsets $\mathbb{A}^2_x$ and $\mathbb{A}^2_y$ by a Čech 1-cocycle of the form $x^{-m}y^{-n}p(x, y)$ where $m, n \geq 0$ and $p(x, y) \in k[x, y]$ is a homogeneous polynomial of degree $r \leq m + n - 2$. Equivalently, $P$ is isomorphic the $\mathbb{G}_a,\mathbb{A}^2$-torsor

$$\rho = \text{pr}_{x,y} : P_{m,n,p} = \{|x|^m y^n u = p(x, y)\} \setminus \{x = y = 0\} \rightarrow \mathbb{A}^2_x,$$

which admits an obvious lift $\lambda : (x, y, u, v) = (\lambda x, \lambda y, \lambda^{-1} u, \lambda^{-1} v)$, where $d = m + n - r$, of the $\mathbb{G}_m$-action on $\mathbb{A}^2_2$. Let $q : \mathbb{A}^2_x \rightarrow \mathbb{A}^2_x / \mathbb{G}_m = \mathbb{P}^1$ be the quotient morphism of the aforementioned $\mathbb{G}_m$-action on $\mathbb{A}^2_x$. Then it follows from [4, Example 1.8] that the inverse image by the canonical isomorphism

$$\bigoplus_{k \in \mathbb{Z}} H^1(\mathbb{P}^1, \mathcal{O}_{\mathbb{P}^1}(k)) \simeq H^1(\mathbb{P}^1, q_* \mathcal{O}_{\mathbb{A}^2}) \rightarrow H^1(\mathbb{A}_2^2, \mathcal{O}_{\mathbb{A}^2})$$

of the isomorphism class $g$ of such an homogeneous torsor is an element $h$ of $H^1(\mathbb{P}^1, \mathcal{O}_p(-d))$. Furthermore, the $\mathbb{G}_m$-equivariant morphism $\rho : P \rightarrow \mathbb{A}^2$ descends to a locally trivial $\mathbb{A}^1$-bundle $\pi : P / \mathbb{G}_m \rightarrow \mathbb{P}^1 = \mathbb{A}^2_2 / \mathbb{G}_m$ which is an $\mathcal{O}_{P^1}(-d)$-torsor with isomorphism class $h \in H^1(\mathbb{P}^1, \mathcal{O}_{P^1}(-d))$.

Since $f^* \mathcal{O}_{P^1}(-d) \simeq \mathcal{O}_{\mathbb{A}^2}(dE)$, the fiber product $W(P, d) = \mathbb{A}^2 \times_{\mathbb{P}^1} P / \mathbb{G}_m$ is equipped via the restriction of the first projection with the structure of an $M(d)$-torsor $\theta : W(P, d) \rightarrow \mathbb{A}^2$ with isomorphism class $f^* h \in H^1(\mathbb{A}_2^2, \mathcal{O}_{\mathbb{A}^2}(dE))$. On the other hand, $W(P, d)$ is a line bundle over $P / \mathbb{G}_m$ via the second projection, hence is an affine threefold as $P / \mathbb{G}_m$ is affine. By construction, we have a commutative diagram

in which each square is cartesian. In other words, $W(P, d)$ is obtained from the $\mathbb{G}_m$-torsor $P \rightarrow P / \mathbb{G}_m$ by “adding the zero section”. The open embedding $j : P \hookrightarrow W(P, d)$ is equivariant for the $\mathbb{G}_a$-action on $W(P, d)$ induced by the canonical global section of $\mathcal{O}_{\mathbb{A}^2}(dE)$ with divisor $dE$ (see Proposition 1.7). By Theorem 2.5, $\theta : W(P, d) \rightarrow \mathbb{A}^2_2$ is the unique $\mathbb{G}_a$-extension of $\rho : P \rightarrow \mathbb{A}^2_2$ with affine total space.

In the simplest case $d = 2$, the unique homogeneous $\mathbb{G}_a,\mathbb{A}^2_2$-torsor is the geometric quotient $\text{SL}_2 \rightarrow \text{SL}_2 / \mathbb{G}_a$ of the group $\text{SL}_2$ by the action of its subgroup of upper triangular unipotent matrices equipped with the diagonal $\mathbb{G}_m$-action, and we recover Example 2.1.

2.3.2. General case. Here, given an arbitrary non trivial $\mathbb{G}_a$-torsor $\rho : P \rightarrow \mathbb{A}^2_2$, we describe a procedure to explicitly determine the unique $\mathbb{G}_a$-extension $\theta : W \rightarrow \mathbb{A}^2_2$ of $P$ with affine total space $W$ from a Čech 1-cocycle $x^{-m}y^{-n}p(x, y)$, where $m, n \geq 0$ and $p(x, y) \in k[x, y]$ is a non zero polynomial of degree $r \leq m + n - 2$, representing the isomorphism class $g \in H^1(\mathbb{A}_2^2, \mathcal{O}_{\mathbb{A}^2})$ of $P$ on the open covering of $\mathbb{A}^2_2$ by the principal open subsets $\mathbb{A}^2_x$ and $\mathbb{A}^2_y$. 

\[\begin{array}{ccc}
W(P, d) & \xrightarrow{j} & P / \mathbb{G}_m \\
\downarrow & & \downarrow \\
\mathbb{P}^1 & \xrightarrow{\pi} & P / \mathbb{G}_m \\
\downarrow & & \downarrow \\
\mathbb{A}^2_x & \xrightarrow{i} & P / \mathbb{G}_m \\
\downarrow & & \downarrow \\
k^2 & \xrightarrow{f} & P / \mathbb{G}_m \\
\downarrow & & \downarrow \\
k^2 & \xrightarrow{q} & P / \mathbb{G}_m \\
\end{array}\]
Write $p(x, y) = p_d + p_{d+1} + \cdots + p_r$ where the $p_i \in k[x, y]$ are the homogeneous components of $p$, and $p_d \neq 0$. In the decomposition
\[
H^1(\mathbb{A}^2_k, \mathcal{O}_{\mathbb{A}^2_k}) \simeq H^1(\mathbb{P}^1, q_* \mathcal{O}_{\mathbb{A}^2_k}) \simeq \bigoplus_{s \in \mathbb{Z}} H^1(\mathbb{P}^1, \mathcal{O}_{\mathbb{P}^1}(s))
\]
a non zero homogeneous component $x^{-m}y^{-n}p_i$ of $x^{-m}y^{-n}p(x, y)$ corresponds to a non zero element of $H^1(\mathbb{P}^1, \mathcal{O}_{\mathbb{P}^1}(-m-n+i))$. On the other hand, since for every $\ell \in \mathbb{Z}$, $\mathcal{O}_{\mathbb{A}^2}(\ell E) = f^* \mathcal{O}_{\mathbb{P}^1}(-\ell)$ and $f : \mathbb{A}^2 \to \mathbb{P}^1$ is the total space of the line bundle $\mathcal{O}_{\mathbb{P}^1}(-1)$, it follows from the projection formula that
\[
H^1(\mathbb{A}^2, \mathcal{O}_{\mathbb{A}^2}(\ell E)) \simeq H^1(\mathbb{P}^1, f_* \mathcal{O}_{\mathbb{A}^2} \otimes \mathcal{O}_{\mathbb{P}^1}(-\ell)) \simeq \bigoplus_{t \geq 0} H^1(\mathbb{P}^1, \mathcal{O}_{\mathbb{P}^1}(t-\ell)).
\]
The image of $x^{-m}y^{-n}p(x, y)$ in $\bigoplus_{s \in \mathbb{Z}} H^1(\mathbb{P}^1, \mathcal{O}_{\mathbb{P}^1}(s))$ belongs to $\bigoplus_{t \geq 0} H^1(\mathbb{P}^1, \mathcal{O}_{\mathbb{P}^1}(t-\ell))$ if and only if $\ell \geq \ell_0 = m + n - d \geq 2$. Given such an $\ell$, the image $(h_1)_{\ell_0} \in \bigoplus_{t \geq 0} H^1(\mathbb{P}^1, \mathcal{O}_{\mathbb{P}^1}(t-\ell))$ of $x^{-m}y^{-n}p(x, y)$ then defines a unique $M(\ell)$-torsor $\theta_\ell : W(P, \ell) \to \mathbb{A}^2$ whose restriction over the complement of $E$ is isomorphic to $\rho : P \to \mathbb{A}^2_\kappa$ when equipped with the action $\mathbb{G}_m$-action induced by the canonical section of $\mathcal{O}_{\mathbb{A}^2}(\ell E)$ with divisor $\ell E$. On the other hand, the restriction of $W|_E \to E$ over $E$ is an $\mathcal{O}_{\mathbb{P}^1}(\ell)$-torsor with isomorphism class $h_0 \in H^1(\mathbb{P}^1, \mathcal{O}_{\mathbb{P}^1}(-\ell))$. By definition, $h_0$ is non zero if and only if $\ell = \ell_0$, and we conclude from Theorem 2.5 that $\theta_{\ell_0} : W(P, \ell_0) \to \mathbb{A}^2$ is the unique $\mathbb{G}_a$-extension of $\rho : P \to \mathbb{A}^2$ with affine total space.

3. Quasi-projective $\mathbb{G}_a$-extensions of Type II

In this section we consider the following subclass of extensions of Type II of a $\mathbb{G}_a$-torsor over a punctured surface.

**Definition 3.1.** A $\mathbb{G}_a$-extension $\pi : X \to S$ of a $\mathbb{G}_a$-torsor $\rho : P \to S$ over a punctured surface $S = S \setminus \{o\}$ is said to be a *quasi-projective* extension of Type II if it satisfies the following properties

i) $X$ is quasi-projective over $S$ and the $\mathbb{G}_a$-action on $X$ is proper,

ii) $X$ is smooth along $\pi^{-1}(o)$ and $\pi^{-1}(o)_{\text{red}} \simeq \mathbb{A}^2_\kappa$.

**Example 3.2.** Let $o = V(x, y)$ be a global scheme-theoretic complete intersection closed point in the smooth locus of a surface $S$ and let $\rho : P \to S \setminus \{o\}$ be the $\mathbb{G}_a$-torsor with defining sheaf of ideals $(xv - yu - 1) \subset O_S[u, v]$ as in Example 2.1. Let $\pi_1 : X_1 \to S$ be the affine $S$-scheme with defining sheaf of ideals $(xw - y(z_1 + 1), xz_2 - z_1(y + 1), z_1w - yz_2) \subset O_S[z_1, z_2, w]$. The morphism of $S$-schemes $j_1 : P \to X_1$ defined by $(x, y, u, v) \mapsto (x, y, u, v, yu)$ is an open embedding, equivariant for the $\mathbb{G}_a$-action on $X_1$ associated with the locally nilpotent $O_S$-derivation $x\partial_z + (2yz_1 + 1)\partial_{z_2} + y^2\partial_w$ of $\pi_1$. The fiber $\pi_1^{-1}(o)$ is isomorphic to $\mathbb{A}^2_\kappa = \text{Spec}(\kappa[z_2, w])$ on which the $\mathbb{G}_a$-action restricts to $\mathbb{G}_a$-action by translations associated to the derivation $\partial_{z_2}$ of $\mathbb{A}^2_\kappa$. It is straightforward to check that $X_1$ is smooth along $\pi_1^{-1}(o)$. We claim that the geometric quotient of $\pi_1$-torsor on $X_1$ is isomorphic to the complement of a $\kappa$-rational point $o_1$ in the blow-up $\tau : \tilde{S} \to S$ of $o$. Such a surface being in particular separated, the $\mathbb{G}_a$-action on $X_1$ is proper, implying that $j_1 : P \to X_1$ is a quasi-projective extension of $P$ of Type II.

Indeed, let us identify $\tilde{S}$ with the closed subvariety of $S \times_k \text{Proj}(k[u_0, u_1])$ with equation $xu_1 - yu_0 = 0$ in such a way that $\tau$ coincides with the restriction of the first projection. The morphism $f : X_1 \to \tilde{S}$ defined by
\[
(x, y, z, u, v) \mapsto ((x, y), [x : y]) = ((x, y), [yz_1 + 1 : w])
\]
is $\mathbb{G}_a$-invariant and maps $\pi_1^{-1}(o)$ dominantly onto the exceptional divisor $E \simeq \text{pr}_1^{-1}(o) \simeq \text{Proj}(\kappa[u_0, u_1])$ of $\tau$. The induced morphism
\[
f|_{\pi_1^{-1}(o)} : \pi_1^{-1}(o) \to \text{Spec}(\kappa[z_2, w]) \to E, \quad (z_2, w) \mapsto [1 : w]
\]
factors as the composition of the geometric quotient $\pi_1^{-1}(o) \to \pi_1^{-1}(o)/\mathbb{G}_a = \text{Spec}(\kappa[w])$ with the open immersion $\pi_1^{-1}(o)/\mathbb{G}_a \hookrightarrow E$ of $\pi_1^{-1}(o)/\mathbb{G}_a$ as the complement of the $\kappa$-rational point $o_1 = ((0, 0), [0 : 1]) \in E$. On the other hand, the composition
\[
\tau \circ f \circ j_1 : P \xrightarrow{\sim} X_1 \setminus \pi_1^{-1}(o) \to \tilde{S} \setminus E \xrightarrow{\sim} S \setminus \{o\}
\]
coincides with the geometric quotient morphism $\rho : P \to S \setminus \{o\}$. So $f : X_1 \to \bar{S}$ factors through a surjective morphism $q : X_1 \to \bar{S} \setminus \{o_1\}$ whose fibers all consist of precisely one $G_a$-orbit. Since $q$ is a smooth morphism, $g$ is a $G_a$-toral which implies that $X_1/G_a \simeq \bar{S} \setminus \{o_1\}$.

The scheme of the classification of quasi-projective extensions of Type II of a given $G_a$-toral $\rho : P \to S_*$ which we give below is as follows: we first construct in §3.1 families of such extensions, in the form of $\mathbb{G}_a$-extensions $q : X \to S'$ over quasi-projective $S$-schemes $\tau : S' \to S$ such that $\tau^{-1}(o)_{\text{red}}$ is isomorphic to $\mathbb{A}^1_{k_0}$, $S'$ is smooth along $\tau^{-1}(o)$, and $\tau : : S' \setminus \tau^{-1}(o) \to S_*$ is an isomorphism. We then show in §3.2 that for quasi-projective $G_a$-extension $\tau : X \to S$ of Type II of a given $G_a$-toral $\rho : P \to S_*$, the structure morphism $\pi : X \to S$ factors through a $G_a$-toral $q : X \to S'$ over one of these $S$-schemes $S'$. In the last subsection, we focus on the special case where $\pi : X \to S$ has the stronger property of being an affine morphism.

### 3.1. A family of $G_a$-extensions over quasi-projective $S$-schemes.

Let again $(S,o)$ be a pair consisting of a surface and a closed point $o$ contained in the smooth locus of $S$, with residue field $\kappa$. We let $\tau_1 : \bar{S}_1 \to S$ be the blow-up of $o$, with exceptional divisor $\bar{E}_1 \simeq \mathbb{P}^1_{\kappa}$. Then for every $n \geq 2$, we let $\tau_{n,1} : \bar{S}_n = \bar{S}_n(o_1, \ldots, o_{n-1}) \to \bar{S}_1$ be the scheme obtained from $\bar{S}_1$ by performing the following sequence of blow-ups of $\kappa$-rational points:

- a) The first step $\tau_{2,1} : \bar{S}_2(o_1) \to \bar{S}_1$ is the blow-up of a $\kappa$-rational point $o_1 \in \bar{E}_1$ with exceptional divisor $\bar{E}_2 \simeq \mathbb{P}^1_{\kappa}$.
- b) Then for every $2 \leq i \leq n - 2$, we let $\tau_{i+1,1} : \bar{S}_{i+1}(o_1, \ldots, o_i) \to \bar{S}_i(o_1, \ldots, o_{i-1})$ be the blow-up of a $\kappa$-rational point $o_i \in \bar{E}_i$, with exceptional divisor $\bar{E}_{i+1} \simeq \mathbb{P}^1_{\kappa}$.
- c) Finally, we let $\tau_{n,n-1} : \bar{S}_n(o_1, \ldots, o_{n-1}) \to \bar{S}_{n-1}(o_1, \ldots, o_{n-2})$ be the blow-up of a $\kappa$-rational point $o_{n-1} \in \bar{E}_{n-1}$ which is a smooth point of the reduced total transform of $\bar{E}_1$ by $\tau_1 \circ \cdots \tau_{n-1,n-2}$.

We let $\bar{E}_n \simeq \mathbb{P}^1_{\kappa}$ be the exceptional divisor of $\tau_{n,n-1}$ and we let $\tau_{n,1} = \tau_{2,1} \circ \cdots \circ \tau_{n,n-1} : \bar{S}_n(o_1, \ldots, o_{n-1}) \to \bar{S}_1$.

The inverse image of $o$ in $\bar{S}_n(o_1, \ldots, o_{n-1})$ by $\tau_1 \circ \tau_{n,1}$ is a tree of $\kappa$-rational curves in which $\bar{E}_n$ intersects the reduced proper transform of $\bar{E}_1 \cup \cdots \cup \bar{E}_{n-1}$ in $\bar{S}_n(o_1, \ldots, o_{n-1})$ transversally in a unique $\kappa$-rational point.

![Figure 3.1]

The successive total transforms of $\bar{E}_1$ in a possible construction of a surface of the form $\bar{S}_n(o_1, \ldots, o_{n-1})$ over a $\kappa$-rational point $o$. The integers indicate the self-intersections of the corresponding curves.

**Notation 3.3.** For every $\kappa$-rational point $o_1 \in \bar{E}_1$, we let $S_1(o_1) = \bar{S}_1 \setminus \{o_1\}$, $E_1 = \bar{E}_1 \setminus S_1 \simeq \mathbb{A}^1_{k_0}$ and we let $\tau_1 : S_1(o_1) \to S$ be the restriction of $\tau_1$.

For $n \geq 2$, we let $S_n(o_1, \ldots, o_{n-1}) = \bar{S}_n(o_1, \ldots, o_{n-1}) \setminus \bar{E}_1 \cdots \cup \bar{E}_{n-1}$ and $E_n = S_n(o_1, \ldots, o_{n-1}) \cap \bar{E}_n \simeq \mathbb{A}^1_{k_0}$. We denote by $\tau_{n,1} : S_n(o_1, \ldots, o_{n-1}) \to S_1$ the birational morphism induced by $\tau_{n,1}$ and we let $\tau_n = \tau_1 \circ \tau_{n,1} : S_n(o_1, \ldots, o_{n-1}) \to S$.

The following lemma summarizes some basic properties of the so-constructed $S$-schemes:

**Lemma 3.4.** For every $n \geq 1$, the following hold for $S_n = S_n(o_1, \ldots, o_{n-1})$:

- a) $\tau_n : S_n \to S$ is quasi-projective and restricts to an isomorphism over $S_*$ while $\tau_n^{-1}(o)_{\text{red}} = E_n$.
- b) $S_n$ is smooth along $\tau_n^{-1}(o)$.
c) \( \tau_n : \Gamma(S, \mathcal{O}_S) \rightarrow \Gamma(S_n, \mathcal{O}_{S_n}) \) is an isomorphism.

Moreover for \( n \geq 2 \), the morphism \( \tau_{n,1} : S_n \rightarrow \overline{S}_1 \) is affine.

Proof. The first three properties are straightforward consequences of the construction. For the last one, let \( D = \overline{E}_1 + \sum_{i=2}^{n-1} a_i \overline{E}_i \) where \( a_i \) is a sequence of positive rational numbers and let \( m \geq 1 \) be so that \( mD \) is a Cartier divisor on \( \overline{S}_n \). Then a direct computation shows that the restriction of \( \mathcal{O}_{\overline{S}_n}(mD) \) to \( \overline{\tau}_{n,1}(o_1)_{\text{red}} = \bigcup_{i=n}^{m-1} \overline{E}_i \) is an ample invertible sheaf provided that the sequence \( (a_i)_{i=2, \ldots, n-1} \) decreases rapidly enough with respect to the distance of \( \overline{E}_i \) to \( \overline{E}_1 \) in the dual graph of \( \overline{E}_1 \cup \cdots \cup \overline{E}_{n-1} \). Since \( \overline{\tau}_{n,1} \) restricts to an isomorphism over \( \overline{S}_1 \setminus \{o_1\} \), it follows from [7, Théorème 4.7.1] that \( \mathcal{O}_{\overline{S}_n}(mD) \) is \( \overline{\tau}_{n,1} \)-ample on \( \overline{S}_n \). Since by definition \( \tau_{n,1} \) is the restriction of the projective morphism \( \tau_{n,1} : \overline{S}_n \rightarrow \overline{S}_1 \) to \( S_n = \overline{S}_n \setminus \overline{E}_1 \cup \cdots \cup \overline{E}_{n-1} = \overline{S}_n \setminus \text{Supp}(D) \), we conclude that \( \tau_{n,1} \) is an affine morphism. \( \square \)

Remark 3.5. By construction, \( \tau_1^{-1}(o) = E_1 \) in \( S_1(o_1) \), but for \( n \geq 2 \), we have \( \tau_n^{-1}(o) = mE_n \) for some integer \( m \geq 1 \) which depends on the sequence of \( \kappa \)-rational points \( o_1, \ldots, o_{n-1} \) blown-up to construct \( S_n(o_1, \ldots, o_{n-1}) \). For instance, it is straightforward to check that \( m = 1 \) if and only if for every \( i \geq 1 \), \( o_i \in \overline{E}_i \) is a smooth point of the reduced total transform of \( \overline{E}_i \) in \( \overline{S}_1(o_1, \ldots, o_{n-1}) \).

The structure morphism of a \( \mathbb{G}_a \)-torsor being affine, hence quasi-projective, the total space of any \( \mathbb{G}_a \)-torsor \( q : X \rightarrow S_n \) over an S-scheme \( \tau_n : S_n = S_n(o_1, \ldots, o_n) \rightarrow S \) is a quasi-projective S-scheme \( \pi = \tau_n \circ q : X \rightarrow S \) equipped with a proper \( \mathbb{G}_a \times S \)-action. Furthermore \( \pi_1^{-1}(o)_{\text{red}} = q_1^{-1}(E_n) \simeq E_n \times \mathbb{G}_a \simeq \mathbb{G}_a \) and \( X \) is smooth along \( \pi_1^{-1}(o) \) as \( S_n \) is smooth along \( E_n \). On the other hand, \( \pi : X \rightarrow S \) is by construction a \( \mathbb{G}_a \)-extension of its restriction \( \rho : P \rightarrow S_n \setminus E_n \simeq S_n \setminus E_n \), and hence is a quasi-projective \( \mathbb{G}_a \)-extension of \( P \) of Type II. The following proposition shows conversely that every \( \mathbb{G}_a \)-torsor \( \rho : P \rightarrow S_n \) admits a quasi-projective \( \mathbb{G}_a \)-extension of Type II into a \( \mathbb{G}_a \)-torsor \( q : X \rightarrow S_n \).

**Proposition 3.6.** Let \( \rho : P \rightarrow S_n \) be a \( \mathbb{G}_a \)-torsor. Then for every \( n \geq 1 \) and every S-scheme \( \tau_n : S_n(o_1, \ldots, o_{n-1}) \rightarrow S \) as in Notation 3.3 there exist a \( \mathbb{G}_a \)-torsor \( q : X \rightarrow S_n(o_1, \ldots, o_{n-1}) \) and an equivariant open embedding \( j : P \rightarrow X \) such that in the following diagram

\[
\begin{array}{ccc}
P & \xymatrix{ \ar[r]^j & X } & \ar[d]^q \\
S_n(o_1, \ldots, o_{n-1}) \setminus E_n & \ar[d]^{\tau_n} \ar[r]_j & S_n(o_1, \ldots, o_{n-1}) \setminus E_n \\
S_n(o_1, \ldots, o_{n-1}) & \ar[d]^{\tau_n} & S_n(o_1, \ldots, o_{n-1}) \setminus E_n \\
S_n & \ar[d] & S_n \setminus E_n \\
S & & S \\
\end{array}
\]

all squares are cartesian. In particular, \( j : P \rightarrow X \) is a quasi-projective \( \mathbb{G}_a \)-extension of \( P \) of Type II.

Proof. Letting \( S_n = S_n(o_1, \ldots, o_n) \), we have to prove that every \( \mathbb{G}_a \)-torsor \( \rho : P \rightarrow S_n \setminus E_n \simeq S_n \) is the restriction of a \( \mathbb{G}_a \)-torsor \( q : X \rightarrow S_n \), or equivalently that the restriction homomorphism \( H^1(S_n, \mathcal{O}_{S_n}) \rightarrow H^1(S_n \setminus E_n, \mathcal{O}_{S_n \setminus E_n}) \) is surjective. It is enough to show that there exists a Zariski open neighborhood \( U \) of \( E_n \) in \( S_n \) and a \( \mathbb{G}_a \)-torsor \( q : Y \rightarrow U \) such that \( Y \mid_{U \setminus E_n} \simeq P \mid_{U \setminus E_n} \). Indeed, if so then a \( \mathbb{G}_a \)-torsor \( q : X \rightarrow S_n \) with the desired property is obtained by gluing \( P \) and \( Y \) over \( U \setminus E_n \) by the isomorphism \( Y \mid_{U \setminus E_n} \simeq P \mid_{U \setminus E_n} \). In particular, we can replace \( S_n \) by the inverse image by \( \tau_n : S_n \rightarrow S \) of any Zariski open neighborhood of \( o \) in \( S \). We can thus assume from the very beginning that \( S = \text{Spec}(A) \) is affine and that \( o = V(f,g) \) is a scheme-theoretic intersection for some \( f, g \in A \). Up to replacing \( f \) and \( g \) by other generators of the maximal ideal of \( o \) in \( A \), we can assume that the proper transform \( L_1 \) of \( S_1 \rightarrow S \) of the curve \( L = V(f) \subset S \) intersects \( \overline{E}_1 \) in \( o_1 \). We denote by \( M_1 \subset \overline{S}_1 \) the proper transform of the curve \( M = V(g) \subset S \).

We first treat the case \( n = 1 \). The open subset \( U_1 = \overline{S}_1 \setminus L \) of \( \overline{S}_1 \) is then affine and contained in \( S_1 \). Furthermore \( U_1 \setminus E_1 = \overline{S}_1 \setminus \overline{\tau}_1^{-1}(L) \simeq S \setminus L \) is also affine. The Mayer-Vietoris long exact sequence of cohomology of \( \mathcal{O}_{S_1} \) for the open covering of \( S_1 \) by \( S_1 \setminus E_1 \) and \( U_1 \) then reads

\[
\cdots \rightarrow H^1(S_1, \mathcal{O}_{S_1}) \rightarrow H^1(U_1, \mathcal{O}_{S_1}) \oplus H^0(S_1 \setminus E_1, \mathcal{O}_{S_1}) \rightarrow H^0(U_1 \setminus E_1, \mathcal{O}_{S_1}) \rightarrow \cdots
\]
Since $U_1 \setminus E_1$ is affine, $H^1(U_1 \setminus E_1, \mathcal{O}_{U_1}) = 0$ and so, the homomorphism $H^1(S_1, \mathcal{O}_{S_1}) \to H^1(S_1 \setminus E_1, \mathcal{O}_{S_1})$ is surjective as desired.

In the case where $n \geq 2$, the open subset $V_1 = \overline{S_1} \setminus M_1$ of $\overline{S_1}$ is affine and it contains $o_1$ since $M_1$ intersects $\overline{E_1}$ in a point distinct from $o_1$. Since $\tau_{n,1} : S_n \to \overline{S_1}$ is an affine morphism by Lemma 3.4, $U_n = \tau_{n,1}(U_1)$ is an affine open neighborhood of $E_n$ in $S_n$. By construction, $S_n$ is then covered by the two open subset $U_n$ and $S_n \setminus E_n$ which intersect along the affine open subset $U_n \cap S_n \setminus E_n = U_n \setminus E_n = \tau_{n,1}(\overline{S_1} \setminus \overline{\tau_{n,1}^{-1}(M)})$ of $S_n$. The conclusion then follows from the Mayer-Vietoris long exact sequence of cohomology of $\mathcal{O}_{S_n}$ for the open covering of $S_n$ by $S_n \setminus E_n$ and $U_n$.

3.2. Classification.

The following theorem shows that every quasi-projective $\mathbb{G}_a$-extension of Type II of a given $\mathbb{G}_a$-torsor $\rho : P \to S_*$ is isomorphic to one of the schemes $q : X \to S_n$ constructed in § 3.1.

**Theorem 3.7.** Let $\rho : P \to S_*$ be a $\mathbb{G}_a$-torsor and let

$$
\begin{array}{ccc}
P & \xrightarrow{j} & X \\
\rho \downarrow & & \downarrow \pi \\
S_* & \xrightarrow{\delta} & S
\end{array}
$$

be a quasi-projective $\mathbb{G}_a$-extension of $P$ of Type II. Then there exists an integer $n \geq 1$ and a scheme $\tau_n : S_n(o_1, \ldots, o_{n-1}) \to S$ such that $X$ is a $\mathbb{G}_a$-torsor $q : X \to S_n(o_1, \ldots, o_{n-1}) \simeq X/\mathbb{G}_a$ and $\rho : P \to S_*$ coincides with the restriction of $q$ to $S_n(o_1, \ldots, o_{n-1}) \setminus E_n$. 

**Proof.** Since the $\mathbb{G}_a,S$-action on $X$ is proper, the geometric quotient $X/\mathbb{G}_a,S$ exists in the form of a separated algebraic $S$-space $\delta : X/\mathbb{G}_a,S \to S$. Furthermore, since by definition of an extension $\pi^{-1}(S_1) \simeq P$, we have $\pi^{-1}(S_1)/\mathbb{G}_a,S \simeq P/\mathbb{G}_a,S \simeq S_*$ and so $\delta$ restricts to an isomorphism over $S_*$. On the other hand, $\pi^{-1}(\alpha) \simeq A^2_\kappa$ is equipped with the induced proper $\mathbb{G}_a,S$-action, whose geometric quotient $A^2_\kappa/\mathbb{G}_a,S$ is isomorphic to $A^1_\kappa$. It follows from the universal property of geometric quotient that $\delta^{-1}(\alpha) = A^2_\kappa/\mathbb{G}_a,S = \kappa^1_\kappa$.

Since $X$ is smooth in a neighborhood of $\pi^{-1}(\alpha)$, $X/\mathbb{G}_a,S$ is smooth in neighborhood of $\delta^{-1}(\alpha)$. In particular, $\pi^{-1}(\alpha)$ and $\delta^{-1}(\alpha)$ are Cartier divisors on $X$ and $X/\mathbb{G}_a,S$ respectively. Let $\overline{\tau}_1 : \overline{S_1} \to S$ be the blow-up of $\alpha$. Then by the universal property of blow-ups [14, Tag 085P], the morphisms $\pi : X \to S$ and $\delta : X/\mathbb{G}_a,S \to S$ lift to morphisms $\pi_1 : X \to \overline{S_1}$ and $\delta_1 : X/\mathbb{G}_a,S \to \overline{S_1}$ respectively, and we have a commutative diagram

$$
\begin{array}{ccc}
X & \xrightarrow{\pi_1} & \overline{S_1} \\
\downarrow \delta_1 & & \downarrow \overline{\tau}_1 \\
X/\mathbb{G}_a & \xrightarrow{\delta} & S
\end{array}
$$

Furthermore, since $\delta : X/\mathbb{G}_a,S \to S$ and $\overline{\tau}_1 : \overline{S_1} \to S$ are separated, it follows that $\delta_1 : X/\mathbb{G}_a,S \to \overline{S_1}$ is separated. By construction, the image of $\pi^{-1}(\alpha)_{\text{red}}/\mathbb{G}_a,S$ by $\delta_1$ is contained in $\overline{E_1}$.

If $\delta_1$ is not constant on $\pi^{-1}(\alpha)_{\text{red}}/\mathbb{G}_a,S$ then $\delta_1$ is a separated quasi-finite birational morphism. Since $\overline{S_1}$ is normal, $\delta_1$ is thus an open immersion by virtue of Zariski Main Theorem for algebraic spaces [14, Tag 05W7]. Since $\pi^{-1}(\alpha)_{\text{red}}/\mathbb{G}_a,S \simeq A^1_\kappa$, the only possibility is that $\overline{S_1} \setminus \delta_1(X/\mathbb{G}_a,S)$ consists of a unique $\kappa$-rational point $o_1 \in \overline{E_1}$ and $\delta_1 : X/\mathbb{G}_a,S \to S_1(\{o_1\}) = \overline{S_1} \setminus \{o_1\}$ is an isomorphism. So $\pi_1 : X \to S_1(\{o_1\})$ is a $\mathbb{G}_a$-torsor whose restriction to $S_1(\{o_1\}) \setminus E_1 \simeq S_*$ coincides with $\rho : P \to S_*$. 

Otherwise, if $\delta_1$ is constant on $\pi^{-1}(\alpha)_{\text{red}}/\mathbb{G}_a,S$, then its image consists of a unique $\kappa$-rational point $o_1 \in \overline{E_1}$. The same argument as above implies that $\pi_1 : X \to \overline{S_1}$ and $\delta_1 : X/\mathbb{G}_a,S \to \overline{S_1}$ lift to a $\mathbb{G}_a,S$-invariant morphism $\pi_2 : X \to \overline{S_2}(\{o_1\})$ and a separated morphism $\delta_2 : X/\mathbb{G}_a,S \to \overline{S_2}(\{o_1\})$ to the blow-up $\overline{\tau}_{2,1} : \overline{S_2}(\{o_1\}) \to \overline{S_1}$ at $o_1$, with exceptional divisor $\overline{E_2}$. If the restriction of $\delta_2$ to $\pi^{-1}(\alpha)_{\text{red}}/\mathbb{G}_a,S$ is not constant then $\delta_2$ is an open immersion and the image of $\pi^{-1}(\alpha)_{\text{red}}/\mathbb{G}_a,S$ is an open subset of $\overline{E_2}$ isomorphic to $A^1_\kappa$. The only possibility is that $\delta_2(\pi^{-1}(\alpha)/\mathbb{G}_a,S) = \overline{E_2} \setminus \overline{E_1}$. Indeed, otherwise $\overline{S_2} \setminus \delta_2(X/\mathbb{G}_a,S)$ would consist of the disjoint union of a point in $\overline{E_2} \setminus (\overline{E_1} \cap \overline{E_2})$ and of the curve $\overline{E_1} \setminus (\overline{E_1} \cap \overline{E_2})$ which is not closed in $\overline{S_2}$, in contradiction to the fact that $\delta_2$ is an open immersion. Summing up, $\delta_2 : X/\mathbb{G}_a,S \to S_2(\{o_1\}) = \overline{S_2}(\{o_1\}) \setminus \overline{E_1}$ is an isomorphism mapping $\pi^{-1}(\alpha)_{\text{red}}/\mathbb{G}_a,S$ isomorphically onto $E_2$. So $\pi_2 : X \to S_2(\{o_1\})$ is a $\mathbb{G}_a$-torsor whose restriction to $S_2(\{o_1\}) \setminus E_2 \simeq S_*$ coincides with $\rho : P \to S_*$. 

Otherwise, if $\delta_2$ is constant on $\pi^{-1}(o)_{\mathrm{red}}/G_{a,\kappa}$, then $\delta_2(\pi^{-1}(o)/G_{a,\kappa})$ is a $\kappa$-rational point $o_2 \in \overline{E}_2$, and there exists a unique minimal sequence of blow-ups $\overline{\tau}_{k+1:k}: \overline{S}_{k+1}(o_1,\ldots,o_k) \to \overline{S}_k(o_1,\ldots,o_{k-1})$, $k = 2,\ldots,m-1$ of successive $\kappa$-rational points $o_k \in \overline{E}_k \subset \overline{S}_k(o_1,\ldots,o_k)$, with exceptional divisor $\overline{\tau}_{k+1:k} \subset \overline{S}_{k+1}(o_1,\ldots,o_k)$ such that $\pi_2: X \to \overline{S}_2(o_1)$ and $\delta_2: X/G_{a,S} \to \overline{S}_2(o_1)$ lift respectively to a $G_{a,S}$-invariant morphism $\pi_m: X \to \overline{S}_m(o_1,\ldots,o_{m-1})$ and a separated morphism $\delta_m: X/G_{a,S} \to \overline{S}_m(o_1,\ldots,o_{m-1})$ with the property that the restriction of $\delta_m$ to $\pi^{-1}(o)_{\mathrm{red}}/G_{a,\kappa}$ is non constant. By Zariski Main Theorem [14, Tag 05W7] again, we conclude that $\delta_m$ is an open immersion, mapping $\pi^{-1}(o)_{\mathrm{red}}/G_{a,\kappa} \simeq A^1_{\kappa}$ isomorphically onto an open subset of $\overline{E}_m \simeq \mathbb{P}^1_{\kappa}$. As in the previous case, the image of $\pi^{-1}(o)_{\mathrm{red}}/G_{a,\kappa}$ in $\overline{E}_m$ must be equal to the complement of the intersection of $\overline{E}_m$ with the proper transform of $\overline{E}_1 \cup \cdots \cup \overline{E}_{m-1}$ in $\overline{S}_m(o_1,\ldots,o_{m-1})$ since otherwise $\overline{S}_m(o_1,\ldots,o_{m-1}) \setminus \overline{E}_m$ would not be closed in $\overline{S}_m(o_1,\ldots,o_{m-1})$. Since $\pi^{-1}(o)_{\mathrm{red}}/G_{a,\kappa} \simeq A^1_{\kappa}$, it follows that $\overline{E}_m$ intersects the proper transform of $\overline{E}_1 \cup \cdots \cup \overline{E}_{m-1}$ in a unique $\kappa$-rational point, implying in turn that $\pi^{-1}(o)_{\mathrm{red}}/G_{a,\kappa}$ is non constant. By Zariski Main Theorem [14, Tag 05W7] again, we conclude that $\delta_m$ is a $\kappa$-rational point of the reduced total transform $\overline{E}_1 \cup \cdots \cup \overline{E}_{m-1}$ of $\overline{E}_1$ in $\overline{S}_{m-1}(o_1,\ldots,o_{m-2})$. Summing up,

$$
\delta_m: X/G_{a,S} \to \overline{S}_m(o_1,\ldots,o_{m-1}) \setminus \overline{E}_1 \cup \cdots \cup \overline{E}_{m-1}
$$

is an isomorphism with an $S$-scheme of the form $S_m(o_1,\ldots,o_{m-1})$ as constructed in §3.1, mapping $\pi^{-1}(o)_{\mathrm{red}}/G_{a,\kappa}$ isomorphically onto $E_m = S_m(o_1,\ldots,o_{m-1}) \setminus \overline{E}_m$. It follows in turn that $\pi_m: X \to S_m(o_1,\ldots,o_{m-1})$ is a $G_{a,S}$-torsor whose restriction to $S_m(o_1,\ldots,o_{m-1}) \setminus E_m \simeq S$, coincides with $\rho: P \to S$. This completes the proof. □

3.3. Affine $G_{a,S}$-extensions of Type II. In this subsection, given a $G_a$-torsor $\rho: P \to S$, we consider the existence of quasi-projective $G_{a,S}$-extensions of Type II

$$
P \xrightarrow{\rho} X \xrightarrow{\pi} S
$$

with the additional for which $X$ is affine over $S$. As in the case of extension to $A^1$-bundles over the blow-up of $o$ treated in §2.2, a necessary condition for the existence of such extensions is that the restriction of $P$ over every open neighborhood of the closed point $o$ in $S$ is non trivial. Indeed, if there exists an affine open neighborhood $U$ of $o$ over which $P$ is trivial, then $P \simeq U \setminus \{o\} \times A^1_{\kappa}$ is strictly affine, hence cannot be the complement of a Cartier divisor $\pi^{-1}(o)$ of any affine $U$-scheme $X|_U$. The next theorem shows that this condition is actually sufficient:

**Theorem 3.8.** Let $\rho: P \to S$ be a $G_a$-torsor such that for every open neighborhood $U$ of $o$ in $S$, the restriction $P \times_S U \to U \setminus \{o\}$ is non trivial. Then for every $n \geq 1$ and every $S$-scheme $\tau_n: S_n(o_1,\ldots,o_{n-1}) \to S$ as in Notation 3.3 there exists a quasi-projective $G_{a,S}$-extension of $P$ of Type II into the total space of a $G_{a,S}$-torsor $q: X \to S_n(o_1,\ldots,o_{n-1})$ for which $\pi = \tau_n \circ q: X \to S$ is an affine morphism.

The following example illustrates the strategy of the proof given below, which consists in constructing such affine extensions $\pi: X \to S$ by performing a well-chosen equivariant affine modification of extensions of $\rho: P \to S$ into locally trivial $A^1$-bundles $\theta: W(P) \to S$ over the blow-up $\tau: \tilde{S} \to S$ of the point $o$.

**Example 3.9.** Let again $X_0$ and $X_1$ be the $G_{a,S}$-extensions of $\rho: P = \{xy = yu = 1\} \to S \setminus \{o\}$ considered in Example 2.1 and 3.2. Recall that $X_0$ and $X_1$ are the affine $S$-schemes in $A^2_{\kappa}$ defined respectively by the equations

$$
X_0: \begin{cases} 
x + y = 0 \\
y - u = 0
\end{cases} \quad \text{and} \quad X_1: \begin{cases} 
x + y = 0 \\
y - u = 0
\end{cases}
$$

equipped with the $G_{a,S}$-actions associated with the locally nilpotent $O_S$-derivations $\partial_0 = x^2\partial_x + xy\partial_y + y^2\partial_y$ and $\partial_1 = x\partial_x + (2yz + 1)\partial_y + 2z^2\partial_z$ respectively.

The morphism $\pi_0: X_0 \to S$ factors through the structure morphism $\theta: X_0 \to \tilde{S}$ of a torsor under a line bundle on the blow-up $\tau: \tilde{S} \to S$ of the origin, with the property that the restriction of $X_0$ to exceptional divisor $E = \mathbb{P}^1_{\kappa}$ of $\tau$ is a nontrivial torsor over the total space of the line bundle $O_{\mathbb{P}^1_{\kappa}}(-2)$.
The $G_a,S$-action on $X_0$ restricts to the trivial one on $X_0|E = \pi_0^{-1}(o)$. More precisely, $\theta_0$ is a global section of the sheaf $\mathcal{T}_{X_0} \otimes \mathcal{O}_{X_0}(-2X_0|E)$ of vector fields on $X_0$ that vanish at order 2 along $X_0|E$. One way to obtain from $X_0$ a $G_a$-extension $\pi : X \to S$ of $\rho : P \to S \setminus \{o\}$ with fiber $\pi^{-1}(o)$ isomorphic to $A^n$ and a fixed point free action is thus to perform an equivariant affine modification which simultaneously replaces $X_0|E$ by a copy of $A^n$ and decreases the “fixed point order of $\theta_0$ along $X_0|E$", typically a modification with divisor $D$ equal to $X_0|E$ and whose center $Z \subset X_0|E$ is supported by a curve isomorphic to $A^n$ which is mapped isomorphically onto its image by the restriction of $\theta$. The birational S-morphism

$$\eta : X_1 \to X_0, \quad (x,y,z_1,z_2,w) \mapsto (x,y,xz_1,yz_1 + 1,w)$$

is equivariant for the $G_a,S$-actions on $X_0$ and $X_1$ and corresponds to an equivariant affine modification of this type: it restricts to an isomorphism outside the fibers of $\pi_0$ and $\pi_1$ over $o$, and it contracts $\pi_1^{-1}(o) = \text{Spec}(k[z_2,w])$ onto the curve $\{p = q - 1 = 0\} \subset \pi_0^{-1}(o) = \{pr - q(q - 1) = 0\}$. This curve is isomorphic to $A^n_k = \text{Spec}(k[r])$ and it is mapped by the restriction

$$\theta|_{\pi_0^{-1}(o)} : \pi_0^{-1}(o) \to \{pr - q(q - 1) = 0\} \to E = \mathbb{P}^1_k \to \mathbb{P}^1$$

of $\theta$ isomorphically onto the complement of the $\kappa$-rational point $[0 : 1] \in \mathbb{P}^1_k$.

**Proof of Theorem 3.8.** By virtue of Theorem 2.5, there exists a unique integer $\ell_0 \geq 2$ such that $\rho : P \to S$ is the restriction of a torsor $\theta_1 : W_1 \to \mathcal{F}_1$ under the line bundle $M_1((\ell_0)) = \text{Spec}(\text{Sym} \mathcal{O}_{\mathcal{F}_1}(-\ell_0)) \to \mathcal{F}_1$, whose total space $W_1$ is affine over $\mathcal{F}_1$. We now treat the case of $S_1(o_1)$ and $S_n(o_1, \ldots, o_{n-1})$, $n \geq 2$ separately.

Given a $\kappa$-rational point $o_1 \in \mathcal{E}_1$, the restriction of $W_1$ over $E_1 = \mathcal{E}_1 \setminus \{o_1\} \simeq A^n_k$ is the trivial $A^n_k$-bundle $E_1 \times A^n_k$. Since on the other hand the restriction $\theta|_{\mathcal{E}_1} : W_1|_{\mathcal{E}_1} \to \mathcal{E}_1$ is a non trivial $\mathbb{P}_E(-\ell_0)$-torsor (see Theorem 2.5), it follows that for every section $s : E_1 \to W_1|_{\mathcal{E}_1}$ the image $Z_1$ of $E_1$ in $W_1|_{\mathcal{E}_1}$ is a closed curve isomorphic to $E_1$. Indeed, otherwise if $Z_1$ is not closed in $W_1|_{\mathcal{E}_1}$ then its closure $\overline{Z}_1$ is a section of $\theta|_{\mathcal{E}_1}$ in contradiction with the fact that $\theta|_{\mathcal{E}_1} : W_1|_{\mathcal{E}_1} \to \mathcal{E}_1$ is a non trivial $\mathbb{P}_E(-\ell_0)$-torsor. Let $D_1 = \theta_1^{-1}(\mathcal{E}_1)$ and let $\sigma_1 : W_1 \to W_1$ be the affine modification of $W_1$ with center $(I_{Z_1}, D_1)$. By virtue of Lemmas 1.9 and 1.10, $\tau_1 \circ \sigma_1 : W_1 \to \mathcal{F}_1$ factors through a torsor $\theta_1 : W_1 \to \mathcal{F}_1 \setminus \{o_1\} = S_1(o_1)$ under the line bundle

$$M_1((\ell_0 - 1)) = \text{Spec}(\text{Sym} \mathcal{O}_{S_1(o_1)}((-\ell_0 + 1)) \to S_1(o_1)).$$

Now since $E_1 \simeq A^n_k$, affine, the restriction of $\theta_1$ over $E_1 \subset S_1(o_1)$ is the trivial $M_1((\ell_0 - 1))$-torsor. Letting $D_2 = \theta_1^{-1}(E_1)$ and $Z_2 \subset D_2$ be any section of $\theta_1|_{D_2} : D_2 \to E_1$, the affine modification $\sigma_2 : W_2 \to W_1$ with center $(I_{Z_2}, D_2)$ is then an $M_1((\ell_0 - 2))$-torsor $\theta_2 : W_2 \to S_1(o_1)$. Iterating this construction $\ell_0 - 1$ times, we reach a $G_a,S_1(o_1)$-torsor $q = \theta_\ell \circ \sigma_1 \circ \cdots \circ \sigma_{\ell_0-1} : X = W_{\ell_0-1} \to S_1(o_1)$. Since $\sigma_i : W_i \to W_{i+1}$ and each $\sigma_i : W_i \to W_{i+1}$, $i \geq 2$, restricts to an isomorphism over the complement of $E_i$, the restriction of $q : X \to S_1(o_1)$ over $E_1 \simeq S_n$ is isomorphic to $\rho : P \to S$. Furthermore, since the morphisms $\sigma_i$, $i = 1, \ldots, \ell_0 + 1$ are affine and $\tau_1 \circ \sigma_1 : W_1 \to S$ is an affine morphism, it follows that

$$\tau_1 \circ q = \tau_1 \circ \sigma_1 \circ \cdots \circ \sigma_{\ell_0-1} : X \to S$$

is an affine morphism. So $q : X \to S_1(o_1)$ is a $G_a$-extension of $\rho : P \to S_n$ with the desired property.

Now suppose that $n \geq 2$. It follows from the construction of the morphism $\tau_{n,i} : S_n \to S_n(o_1, \ldots, o_{n-1}) \to \mathcal{F}_1$ given in subsection 3.1 that $\tau_{n,i} \mathcal{O}_{\mathcal{F}_1}((mE_n)) \simeq \mathcal{O}_{S_n}(mE_n)$ for some $m \geq 2$. The fiber product $W_n = W_1 \times \pi_1 S_n$ is thus a torsor $\theta_n : W_n \to S_n$ under the line bundle

$$M_n(m) = \text{Spec}(\text{Sym} \mathcal{O}_{S_n}(-mE_n)) \to S_n$$

whose restriction to $S_n \setminus E_n \simeq S_n$ is isomorphic to $\rho : P \to S_n$. Furthermore, since $\tau_{n,i}$ is an affine morphism by virtue of Lemma 3.4, so is the projection $pr_{W_i} : W_n \to W_1$. Since $\tau_1 \circ \theta_1 : W_1 \to S$ is an affine morphism, we conclude that $\tau_n \circ \theta_n = \tau_1 \circ \sigma_1 \circ \cdots \circ \sigma_{\ell_0} \circ \theta_n = \tau_1 \circ \theta \circ pr_{W_1} : W_n \to S$ is an affine morphism as well. Since $E_n \simeq A^n_k$, the restriction of $\theta_n$ over $E_n$ is the trivial $M_n(m)|_{E_n}$-torsor. The desired $G_a,S_n$-torsor $q : X \to S_n$, extending $\rho : P \to S_n$ is then obtained from $\theta_n : W_n \to S_n$ by performing a sequence of $m$ successive affine modifications similar to those applied in the previous case.

**Remark 3.10.** In the case where $S$ is affine, the total spaces $X$ of the varieties $q : X \to S_n(o_1, \ldots, o_{n-1})$ of Theorem 3.8 are all affine. To our knowledge, these are the first instances of smooth affine threefolds
equipped with proper $G_a$-actions whose geometric quotients are smooth quasi-projective surfaces which are not quasi-affine.

We do not know in general if under the conditions of Theorem 3.8 every quasi-projective $G_a$-extensions of $P$ of Type II into the total space of a $G_a$-torsor $q : X \to S_n(o_1, \ldots, o_{n-1})$ has the property that $\pi = \tau_n \circ q : X \to S$ is an affine morphism. In particular, we ask the following:

**Question 3.11.** Is the total space $X$ of a quasi-projective $G_a$-extension $\pi : X \to K^2$ of $\rho = \pr_{x,y} : SL_2 = \{(xv - yu = 1) \to K^2$ of Type II always an affine variety?

#### 3.4. Examples.

In the next paragraphs, we construct two countable families of quasi-projective $G_a$-extensions of the $G_a$-torsor $SL_2 \to SL_2/G_a \simeq K^2 \setminus \{(0,0)\}$ of Type II with affine total spaces. As a consequence of [10, Section 3], for any nontrivial $G_a$-torsor $\rho : P \to S$ on a local punctured surface $S$, these provide, by suitable base changes, families of examples of $G_a$-extensions of $P$ whose total spaces are all affine over $S$.

**3.4.1. A family of $G_a$-extensions of $SL_2$ of “Type II-A”.** Let $S = K^2 = \Spec(k[x,y])$ and let $X_n \subset K^3_{S,n+2} = \Spec(k[x,y][z_1, z_2, y_1, \ldots, y_n])$, $n \geq 1$, be the smooth threefold defined by the system of equations

\[
\begin{align*}
y_iy_j - y_joy & = 0 \quad i, j, k, \ell = 0, \ldots, n, \ i + j = k + \ell \\
z_2y_i - z_1y_{i+1} & = 0 \quad i = 0, \ldots, n - 1 \\
x_0y_{i+1} - y_1(y_0z_1 + 1) & = 0 \quad i = 0, \ldots, n - 1 \\
x_{i+2} - z_1(y_0z_1 + 1) & = 0.
\end{align*}
\]

The threefold $X_n$ can be endowed with a fixed point free $G_a,S$-action induced by the locally nilpotent $k[x,y]$-derivation

\[
(x, y, u, v) \mapsto (x, u, uv, y, yv^2, \ldots, y^nv)
\]

of its coordinate ring. The scheme-theoretic fiber over $o = \{(0,0)\}$ of the $G_a$-invariant morphism $\pi_n = \pr_{x,y} : X_n \to S$ is isomorphic $K^2 = \Spec(k[z_2,y_n])$, on which the induced $G_a$-action is a translation induced by the derivation $\partial_{z_2}$ of $k[z_2,y_n]$. On the other hand, the morphism $j : SL_2 = \{xy - y_0u = 1\} \to X_n$ defined by

\[
(x, y, u, v) \mapsto (x, u, uv, y, yv^2, \ldots, y^nv)
\]

is an equivariant open embedding of $SL_2$ equipped with the $G_a$-action induced by the locally nilpotent derivation $x\partial_u + y_0\partial_v$ of its coordinate ring into $X_n$ with image equal to $\pi^{-1}(K^2 \setminus \{o\})$. So $j : SL_2 \hookrightarrow X_n$ is a quasi-projective $G_a$-extension of $SL_2$ into the affine variety $X_n$, with $\pi_n^{-1}(o) \simeq K^2$.

The restrictions of the projection $K^3_{S,n+2} \to K^3_{S,n+2}$ onto the first $n + 2$ variables induce a sequence of $G_a$-equivariant birational morphisms $\sigma_{n+1,n} : X_{n+1} \to X_n$. The threefolds $X_n$ thus form a countable tower of $G_a$-equivariant affine modifications of $X_1$. It follows from Example 3.2 that $X_1$ is a quasi-projective extension of $SL_2$ of Type II with geometric quotient isomorphic to a quasi-projective surface of the form $S_1(\alpha_1)$. More generally, we have the following result.

**Proposition 3.12.** For every $n \geq 2$, the morphism $j : SL_2 \hookrightarrow X_n$ is a quasi-projective $G_a$-extension of Type II. The geometric quotient $X_n/G_a$ is isomorphic to a quasi-projective surface $S_n = S_n(o_1, \ldots, o_n)$ as in § 3.1 for which $S_n(o_1, \ldots, o_{n-1}) \setminus S_n$ consists of a chain of $n - 1$ smooth rational curves with self-intersection $-2$, i.e. the exceptional set of the minimal resolution of a surface singularity of type $A_n$.

**Proof.** To see this, we consider the following sequence of blow-ups: the first one $\mathfrak{T}_1 : \mathfrak{S}_1 \to U_0 = K^2$ is the blow-up of the origin, with exceptional divisor $\mathfrak{E}_1$, and we let $U_1 \simeq K^2 = \Spec(k[x, w_1])$ be the affine chart of $\mathfrak{S}_1$ on which $\mathfrak{T}_1 : \mathfrak{S}_1 \to K^2$ is given by $(x, w_1) \mapsto (x, xw_1)$. Then we let $\mathfrak{T}_{2,1} : \mathfrak{X}_2(o_1) \to \mathfrak{S}_1$ be the blow-up of the point $o_1 = (0,0) \in U_1 \subset \mathfrak{S}_1$ with exceptional divisor $\mathfrak{E}_2$, and we let $U_2 \simeq K^2 = \Spec(k[x, w_2])$ be the affine chart of $\mathfrak{S}_2(o_1)$ on which the restriction of $\mathfrak{T}_{2,1} : \mathfrak{X}_2(o_1) \to \mathfrak{S}_1$ coincides with the morphism $U_2 \to U_1$, $(x, w_2) \mapsto (x, xw_2)$. For every $2 < m \leq n$, we define by induction the blow-up

\[
\mathfrak{T}_{m,m-1} : \mathfrak{S}_m(o_1, \ldots, o_{m-1}) \to \mathfrak{S}_{m-1}(o_1, \ldots, o_{m-2})
\]
of the point \( o_{m-1} = (0, 0) \in U_{m-1} \subset \mathfrak{S}_{m-1}(o_1, \ldots, o_{m-2}) \) with exceptional divisor \( \mathcal{E}_m \) and we let \( U_m \cong k^2 = \text{Spec}(k[x, w_m]) \) be the affine chart of \( \mathfrak{S}_m(o_1, \ldots, o_{m-1}) \) on which the restriction of \( \mathfrak{S}_{m-1} \) coincides with the morphism \( U_m \to U_{m-1}, (x, u_m) \mapsto (x, xu_m) \). By construction, we have a commutative diagram

\[
\begin{array}{ccc}
\mathfrak{S}_n(o_1, \ldots, o_{n-1}) & \xrightarrow{\tau_{n-1,n}} & \mathfrak{S}_{n-1}(o_1, \ldots, o_{n-2}) \\ \mathcal{E}_n \downarrow & & \mathcal{E}_{n-1} \\
U_n \to U_{n-1} & & \cdots
\end{array}
\]

The total transform of \( \mathcal{E}_1 \) in \( \mathfrak{S}_n(o_1, \ldots, o_{n-1}) \) is a chain \( \mathcal{E}_1 \cup \mathcal{E}_2 \cup \cdots \cup \mathcal{E}_{n-1} \cup \mathcal{E}_n \) is a chain formed of \( n - 1 \) curves with self-intersection \(-2\) and the curve \( \mathcal{E}_n \), which has self-intersection \(-1\).

![Figure 3.2. Dual graph of the total transform of \( \mathcal{E}_1 \) in \( \mathfrak{S}_n(o_1, \ldots, o_n) \).](image)

The morphism \( \pi : X_n \to S \) lifts to a morphism \( \pi_1 : X_n \to \mathfrak{S}_1 \) defined by

\[
(x, z_1, z_2, y_0, y_1, \ldots, y_n) \mapsto ((x, y_0), (x : y_0)) = ((x, y), [y_0z_1 + 1 : y_1]).
\]

This morphism contracts \( \pi^{-1}(o) \) onto \( o_1 = ((0, 0), [1 : 0]) \) of the exceptional divisor \( \mathcal{E}_1 \) of \( \mathfrak{S}_1 \). The induced rational map \( \pi_1 : X_n \dashrightarrow U_1 \) is given by

\[
(x, z_1, z_2, y_0, y_1, \ldots, y_n) \mapsto (x, \frac{y_1}{y_0z_1 + 1})
\]

and it contracts \( \pi^{-1}(o) \) onto \( o_1 = (0, 0) \). So \( \pi_1 \) lifts to a morphism \( \pi_2 : X_n \to \mathfrak{S}_2(o_1) \), and with our choice of charts, the induced rational map \( \pi_2 : X_n \dashrightarrow U_2 \) is given by

\[
(x, z_1, z_2, y_0, y_1, \ldots, y_n) \mapsto (x, \frac{y_2}{(y_0z_1 + 1)^2})
\]

If \( n = 2 \) then the image of \( \pi^{-1}(o) = \text{Spec}(k[z_2, y_2]) \) by \( \pi_2 \) is equal to \( \mathcal{E}_2 \cap U_2 \) and \( \pi_2^{-1}(\mathcal{E}_2 \cap U_2) \) is equivariantly isomorphic to \( (\mathcal{E}_2 \cap U_2) \times \text{Spec}(k[z_2]) \) on which \( \mathbb{G}_a \) acts by translations on the second factor. So \( \pi_2 : X_n \to \mathfrak{S}_2(o_1) \) factors through a \( \mathbb{G}_a \)-bundle \( \mathcal{E}_2 : X_2 \to S_2(o_1) = \mathfrak{S}_2(o_1) \setminus \mathcal{E}_1 \) and \( X_2/\mathbb{G}_a \cong S_2(o_1) \). Otherwise, if \( n > 2 \) then \( \pi_2 \) contracts \( \pi^{-1}(o) \) onto \( o_2 = (0, 0) \in \mathcal{E}_2 \cap U_2 \subset \mathfrak{S}_2(o_1) \). So \( \pi_2 : X_n \to \mathfrak{S}_2(o_1) \) lifts to a morphism \( \pi_3 : X_n \to \mathfrak{S}_3(o_1, o_2) \). With our choice of charts, for each \( 2 < m < n \), the induced rational map \( \pi_m : X_n \dashrightarrow U_m \) is given by

\[
(x, z_1, z_2, y_0, y_1, \ldots, y_n) \mapsto (x, \frac{y_m}{(y_0z_1 + 1)^m})
\]

hence contracts \( \pi^{-1}(o) \) onto \( o_m = (0, 0) \in U_m \subset \mathfrak{S}_m(o_1, \ldots, o_{m-1}) \). It thus lifts to a morphism \( \pi_m : X_n \to \mathfrak{S}_m(o_1, \ldots, o_{m-1}) \). At the last step, the image of \( \pi^{-1}(o) = \text{Spec}(k[z_2, y_2]) \) by the rational map \( \pi_n : X_n \dashrightarrow U_n \) induced by \( \pi_n : X_n \to \mathfrak{S}_n(o_1, \ldots, o_{n-1}) \) is equal to \( \mathcal{E}_n \cap U_n \), and we conclude as above that \( \pi_n : X_n \to \mathfrak{S}_n(o_1, \ldots, o_{n-1}) \) factors through a \( \mathbb{G}_a \)-bundle

\[
q_n : X_n \to S_n(o_1, \ldots, o_{n-1}) = \mathfrak{S}_n(o_1, \ldots, o_{n-1}) \setminus (\mathcal{E}_1 \cup \cdots \cup \mathcal{E}_{n-1})
\]

hence that \( X_n/\mathbb{G}_a \) is isomorphic to the quasi-projective surface \( S_n(o_1, \ldots, o_{n-1}) \). \( \square \)

### 3.4.2. A family of \( \mathbb{G}_a \)-extensions of \( SL_2 \) of “Type II-D”

To conclude this section, we present an illustration of the proof of Theorem 3.8 another countable family of quasi-projective \( \mathbb{G}_a \)-extensions of \( SL_2 \) of Type II with affine total spaces.

Let again \( \pi_1 : \mathfrak{S}_1 \to S = \mathbb{A}^2 \) be the blow-up of the origin \( o = \{(0, 0)\} \in \mathbb{A}^2 = \text{Spec}(k[x, y]) \) with exceptional divisor \( \mathcal{E}_1 \cong \mathbb{P}^1 \), identified with closed subvariety of \( \mathbb{A}^2 \times \mathbb{P}^1_{x_0, y_0} \) with equation \( xy_1 - yx_0 = 0 \) in such a way that \( \pi \) coincides with the restriction of the first projection. The second projection identifies \( \mathfrak{S}_1 \) with the total space \( p : \mathfrak{S}_1 \to \mathbb{P}^1 \) of the invertible sheaf \( \mathcal{O}_{\mathbb{P}^1}(-1) \). We fix trivializations \( p^{-1}(U_{\infty}) = \text{Spec}(k[z_{\infty}][u_{\infty}]) \) and \( p^{-1}(U_0) = \text{Spec}(k[z_0][u_0]) \) over the open subsets \( U_{\infty} = \mathbb{P}^1 \setminus \{(0 : 1)\} = \text{Spec}(k[z_{\infty}]) \). 

and \( U_0 = \mathbb{P}^1 \setminus \{ [1 : 0] \} = \text{Spec}(k[z_0]) \) in such a way that the gluing of \( p^{-1}(U_\infty) \) and \( p^{-1}(U_0) \) over \( U_0 \cap U_\infty \) is given by the isomorphism \((z_0, u_0) \mapsto (z_\infty, u_\infty) = (z_0^{-1}, z_0 u_0)\).

For every \( n \geq 1 \), we let \( S_{2n+3,0} = \text{Spec}(k[z_0, u_0^{-1}]) \),

\[
S_{2n+3,\infty} = \text{Spec}(k[z_\infty, u_\infty, v_\infty]/(u_\infty^n v_\infty - z_\infty^2 - u_\infty)),
\]

and we let \( S_{2n+3} \) be the surface obtained by gluing \( S_{2n+3,0} \) and \( S_{2n+3,\infty} \) along the open subsets \( S_{2n+3,0} \setminus \{ z_0 = 0 \} \) and \( S_{2n+3,\infty} \setminus \{ z_\infty = u_\infty = 0 \} \) by the isomorphism

\[
(z_0, u_0) \mapsto (z_\infty, u_\infty, v_\infty) = (z_0^{-1}, z_0 u_0, (z_0 u_0)^{-n}(z_0^{-2} + z_0 u_0)).
\]

The canonical open immersion \( S_{2n+3,0} \hookrightarrow p^{-1}(U_0) \) and the projection \( p_{z_\infty,u_\infty} : S_{2n+3,\infty} \to p^{-1}(U_\infty) \) glue to a global birational affine morphism \( \tau_{2n+3,1} : S_{2n+3} \to \mathcal{F}_1 \) restricting to an isomorphism \( S_{2n+3} \setminus \{ z_\infty = u_\infty = 0 \} \to \mathcal{F}_1 \setminus \mathcal{F}_1 \) where we identified the closed subset \( E_{2n+3} = \{ z_\infty = u_\infty = 0 \} \approx \text{Spec}(k[v_\infty]) \) of \( S_{2n+3,\infty} \) with its image in \( S_{2n+3} \). We leave to the reader to check that with the notation of § 3.1, \( S_{2n+3} = S_{2n+3}(o_1, \ldots, o_{2n+2}) \) for a surface \( \mathcal{F}_{2n+3,1} : \mathcal{F}_{2n+3,1}(o_1, \ldots, o_{2n+2}) \to \mathcal{F}_1 \) obtained by first blowing-up the point \( o_1 = (0,0) \in p^{-1}(U_\infty) \) with exceptional divisor \( \mathcal{E}_2 \), then the point \( o_2 = \mathcal{E}_1 \cap \mathcal{E}_2 \) with exceptional divisor \( \mathcal{E}_3 \), then a point \( o_3 \in \mathcal{E}_3 \setminus (\mathcal{E}_1 \cup \mathcal{E}_2) \) with exceptional divisor \( \mathcal{E}_4 \) and then a sequence of points \( o_i \in \mathcal{E}_i \setminus \mathcal{E}_{i-1}, i = 5, \ldots, 2n + 2 \) in such a way that the total transform of \( \mathcal{E}_1 \) in \( S_{2n+3,1} \) is a tree depicted in Figure 3.3. Letting \( \tau_{2n+3} = \tau_1 \circ \tau_{2n+3,1} : S_{2n+3} \to \mathbb{A}^2 \), we have \( \tau_{2n+3,1}^{-1}(o)_{\text{red}} = E_{2n+3} \simeq \mathbb{A}^1 \) and \( \tau_{2n+3}^{-1}(o) = 2E_{2n+3} \).

**Figure 3.3.** Dual graph of the total transform of \( \mathcal{F}_1 \) in \( \mathcal{S}_{2n+3}(o_1, \ldots, o_{2n+2}) \).

Now we let \( q : X_{2n+3} \to S_{2n+3} \) be the \( \mathbb{G}_a \)-bundle defined as the gluing of the trivial \( \mathbb{G}_a \)-bundles \( X_{2n+3,0} = S_{2n+3,0} \times \text{Spec}(k[t_0]) \) and \( X_{2n+3,\infty} = S_{2n+3,\infty} \times \text{Spec}(k[t_\infty]) \) over \( S_{2n+3,0} \) and \( S_{2n+3,\infty} \) respectively along the open subsets \( X_{2n+3,0} \setminus \{ z_0 = 0 \} \) and \( X_{2n+3,\infty} \setminus \{ z_\infty = u_\infty = 0 \} \) by the \( \mathbb{G}_a \)-equivariant isomorphism

\[
(z_0, u_0, t_0) \mapsto (z_\infty, u_\infty, v_\infty, t_\infty) = (z_0^{-1}, z_0 u_0, (z_0 u_0)^{-n}(z_0^{-2} + z_0 u_0), t_0 + z_0^{-1} u_0^{-2}).
\]

Let \( \tau_{2n+3} = \tau_1 \circ \tau_{2n+3,1} \circ q : X_{2n+3} \to \mathbb{A}^2 \).

**Proposition 3.13.** For every \( n \geq 1 \), the variety \( X_{2n+3} \) is affine and there exists a \( \mathbb{G}_a \)-equivariant open embedding \( j : \text{SL}_2 \to X_{2n+3} \) which makes \( \tau_{2n+3} : X_{2n+3} \to \mathbb{A}^2 \) a quasi-projective \( \mathbb{G}_a \)-extension of \( \text{SL}_2 \) of Type II, with fiber \( \tau_{2n+3}^{-1}(o) \) isomorphic to \( \mathbb{A}^2 \) of multiplicity two, and geometric quotient \( X_{2n+3}/\mathbb{G}_a \simeq S_{2n+3} \).

**Proof.** Let \( j_1 : \text{SL}_2 \hookrightarrow W = W(\text{SL}_2, 2) \) be the \( \mathbb{G}_a \)-extension of \( \text{SL}_2 \) into a locally trivial \( \mathbb{A}^1 \)-bundle \( \theta : W \to \mathcal{S}_1 \) with affine total space constructed in Example 2.1. Recall that the image of \( j_1 \) coincides with the restriction of \( \theta \) to \( \mathcal{S}_1 \setminus \mathcal{E}_1 = \mathbb{A}^2 \setminus \{ 0 \} \). With our choice of coordinates, the open subsets \( W_0 = \theta^{-1}(q^{-1}(U_0)) \) and \( W_\infty = \theta^{-1}(q^{-1}(U_\infty)) \) of \( W \) are respectively isomorphic to \( p^{-1}(U_0) \times \text{Spec}(k[w_0]) \) and \( p^{-1}(U_\infty) \times \text{Spec}(k[w_\infty]) \) glued over \( U_0 \cap U_\infty \) by the isomorphism

\[
(z_0, u_0, w_0) \mapsto (z_\infty, u_\infty, w_\infty) = (z_0^{-1}, z_0 u_0, z_0^2 w_0 + z_0).
\]

The \( \mathbb{G}_a \)-action on \( W_0 \) and \( W_\infty \) is given respectively by \( \alpha \cdot (z_0, u_0, w_0) = (z_0, u_0, w_0 + \alpha u_0^2) \) and \( \alpha \cdot (z_\infty, u_\infty, w_\infty) = (z_\infty, u_\infty, w_\infty + \alpha w_\infty^2) \).

Let \( W' = W \times_{\mathcal{S}_1} S_{2n+3} \), equipped with the natural lift of the \( \mathbb{G}_a \)-action on \( W \). Since \( \tau_{2n+3,1} : S_{2n+3} \to \mathcal{S}_1 \) restricts to an isomorphism over \( \mathcal{S}_1 \setminus \mathcal{E}_1 \), the composition \( j' = \tau_{2n+3,1}^{-1} \circ j_1 : \text{SL}_2 \to W' \) is a \( \mathbb{G}_a \)-equivariant open embedding. Furthermore, since \( W \) is affine and \( \tau_{2n+3,1} \) is an affine morphism, it follows
that $W'$ is affine. By construction, $W'$ is covered by the two open subsets
\[
\begin{cases}
W'_0 = W \times_{p^{-1}(U_0)} S_{2n+3,0} \cong S_{2n+3,0} \times \text{Spec}(k[w_0]) \\
W'_{\infty} = W \times_{p^{-1}(U_{\infty})} S_{2n+3,\infty} \cong S_{2n+3,\infty} \times \text{Spec}(k[w_{\infty}]).
\end{cases}
\]

The local $G_a$-equivariant morphisms
\[
\begin{cases}
\beta_0 : X_{2n+3,0} = S_{2n+3,0} \times \text{Spec}(k[t_0]) \to W'_0 \\
\beta_{\infty} : X_{2n+3,\infty} = S_{2n+3,\infty} \times \text{Spec}(k[t_{\infty}]) \to W'_{\infty}
\end{cases}
\]
of schemes over $S_{2n+1,0}$ and $S_{2n+3,\infty}$ respectively defined by $t_0 \mapsto w_0 = u_0^2 t_0$ and $t_{\infty} \mapsto w_{\infty} = u_{\infty}^2 t_{\infty}$ glue to a global $G_a$-equivariant birational affine morphism $\beta : X_{2n+3} \to W'$, restricting to an isomorphism over $S_{2n+3} \setminus E_{2n+3} \cong \mathbb{A}^2 \setminus \{0\}$. Summing up, $X_{2n+3}$ is affine over $W'$ hence affine, and the composition $\beta^{-1} \circ j' : SL_2 \to X_{2n+3}$ is a $G_a$-equivariant open embedding which realizes $\pi : X_{2n+3} \to \mathbb{A}^2$ as a $G_a$-extension of $SL_2$ of Type II with affine total space. By construction, $\pi^{-1}_{2n+3}(o) = q^{-1}(2E_{2n+3})$ is isomorphic to $\mathbb{A}^2$, with multiplicity two, while the geometric quotient $X_{2n+3}/G_a$ is isomorphic to $S_{2n+3}$. $\square$

Remark 3.14. For every $n \geq 1$, the birational morphism $S_{2(n+1)+3,\infty} \to S_{2n+3,\infty}$, $(z_{\infty}, u_{\infty}, v_{\infty}) \mapsto (z_{\infty}, u_{\infty}, v_{\infty})$ extends to a birational morphism $S_{2(n+1)+3} \to S_{2n+3}$ which lifts in turn in a unique way to a $G_a$-equivariant birational morphism $\gamma_{n+1,n} : X_{2(n+1)+3} \to X_{2n+3}$. So in a similar way as for the family constructed in § 3.4.1, the family of threefolds $X_{2n+3}$, $n \geq 1$, form a tower of $G_a$-equivariant affine modifications of the initial one $X_5$.
