Predictive Control Based on Nonlinear Observer for Muscular Force and Fatigue Model

T. Bakir$^1$, B. Bonnard$^2$ and S. Othman$^3$

Abstract— The Functional Electrical Stimulation (FES) is used in the case of neurological disorders (paralyzed muscles) or the muscle reinforcement (sportsmen). A recent model was proposed coupling a force model and a fatigue model. Based on the specific structure of the model, we present a predictive control scheme using online estimation of the fatigue variables with a nonlinear observer. It is numerically tested in a preliminary study.

I. INTRODUCTION

Functional Electrical Stimulation (FES) consists of sending an electrical stimulation to the muscle in order to produce functional movements. FES can be used for muscular reinforcement or for muscles reeducation. In the case of paralysis, FES led to activate the paralyzed muscles to produce movements. However, current FES-system induces a muscular fatigue and imprecise movements [1].

The simplest models are force models of [2], [3] and a more sophisticated model was proposed by [4], [5], [6], [7] where the force model is coupled to the fatigue model. This led to a five dimensional set of differential equations where the input is a train of electrical stimulations whose aim is to produce a force response.

Only few works used Ding model to design an optimized train of pulses to control the force level. [8], [9], [10] used a Model-Free Control (MFC), a predictive strategy (experimental case) and a nonlinear technique (input output linearization) to control the force level, respectively.

Our contribution is to make a preliminary analysis of the control problem in the frame of development of recent techniques in nonlinear control based on the design of a high-gain nonlinear observer, adapting the technique of [11] to our study to perform an inline fatigue parameters estimation. It is used to design a predictive control and improving the results of [10]. A sequence of preliminary numeric simulations is presented to validate the pertinence of the techniques.

The article is organized in 4 sections. In section 2, the force-fatigue model is presented and analyzed. In section 3, a prior estimation of the sensitivity of the fatigue variables-parameters are analyzed and used to the design of the high-gain nonlinear observer. The predictive control scheme is presented. The final section 4 is devoted to the numerical study of the force control problem to bring the force to the reference force based on the inline estimation of the fatigue state variables. Note that it is a preliminary control strategy aiming to test the validity of the observer to provide more sophisticated optimal control strategy for this specific problem.

II. MATHEMATICAL FORCE-FATIGUE MODEL

We consider the force-fatigue model developed by [6], [7], this model could be decomposed in two subsystems. The first system is the force model, where the force is controlled using the $C_N$ variable which takes into account the calcium kinetics and the calcium-troponin interaction during the muscle activation. It can be written as:

$$\frac{dC_N}{dt} = E_s(t) - \frac{C_N}{\tau_c}$$  (1)

$$\frac{dF}{dt} = A \frac{C_N}{K_m + C_N} - \frac{F}{\tau_1 + \tau_2 \frac{C_N}{K_m + C_N}}$$  (2)

Where in Eq. (1), $A$, $\tau_1$ and $K_m$ are the variables of the fatigue model. The function $E_s(t)$ represents the control variables consisting to electrical stimulations:

$$E_s(t) = \frac{1}{\tau_c} \sum_{i=1}^{n} \eta_i H(t - t_i) R_i \exp(-\frac{t - t_i}{\tau_c})$$  (3)

associated to $n$ pulses $0 = t_1 < t_2 < \ldots < t_n < T$ over the period. $H(t - t_i)$ is the Heaviside step function: $= 0$, $t < t_i$, $= 1$, $t \geq t_i$

Table I gives definition and details of the symbols used in the above equations, $R_i$ in Eq. (1) is a scaling term that accounts for the nonlinear summation of the calcium transient in response to two consecutive pulses, and is given by:

$$R_i = \begin{cases} 1 + (R_0 - 1) \exp(-\frac{t_i - t_{i-1}}{\tau_c}) & \text{for } i = 1 \\ 1 & \text{for } i > 1. \end{cases}$$  (4)

Note that in Eq. (3) appear the (discrete) control variables which consist into:

- The interpulse: $I_i := t_i - t_{i-1}$ for $i > 1$. If fixed, it is denoted $I_i$.
- The scaling factor $\eta_i$ which is the tuning factor of the applied electric intensity.

The second part of the model is the additional fatigue model which describes the changes of parameters ($A$, $K_m$, $\tau_1$) in the force model during the fatigue conditions, it consists into the three differential equations Eqs. (5)–(7):

$$\frac{dA}{dt} = -\frac{A - A_{\text{rest}}}{\tau_{\text{fat}}} + \alpha_A F$$  (5)
Concerning the force model, a first useful result is the details of the symbols of the fatigue model.

**Proposition 1.** Assuming $A$, $K_m$ and $\tau_1$ be fixed, the force model can be integrated by quadrature using a time reparameterization.

**Proof.** Eq. (2) can be written as:

$$\frac{dF(t)}{dt} = a(t) + b(t)F(t)$$  \hspace{1cm} (8)

where $a(t)$ and $b(t)$ are obtained by integrating Eq. (1). Since $b(t)$ is $\neq 0$, Eq. (8) can be written as:

$$\frac{dF(t)}{b(t)dt} = c(t) + F(t),$$  \hspace{1cm} (9)

and by setting

$$ds = b(t)dt$$  \hspace{1cm} (10)

the integration of Eq. (9) is straightforward. \hfill \square

**FES stimulation:** clearly the electrical stimulation $E_s(t)$: $0 = t_1 < t_2 < ... < t_n < T$ decomposes into a period of stimulation $0 = t_1 < ... < t_k$ followed by a period of rest. Fig. 1 represents the stimulation pulses with $I = 50\,ms$, $\eta_i = 0.8$ during a stimulation period of 1s $t_1 \rightarrow t_2$ and $\eta_i = 0$ during a rest period of 1s $t_{21} \rightarrow t_{40}$. In practice, period of stimulation and period of rest are repeated many times.

![Stimulation pulses example](image)

Fig. 1. Stimulation pulses example (amplitude $\eta_i = 0.8$ during the stimulation time of 1s and $\eta_i = 0$ during the rest time of 1s with a constant interpulse $I = 50\,ms$)

### III. Estimation of the State Variables of the Force Fatigue Model

The model used for this study (five state variables) is based on force measurements collected from a set of subjects. Thus, the accuracy of the calculated parameters is directly related to these persons. In this study, we suppose that initial conditions are different following the subject under study. That is why, we need to estimate some of these five initial conditions. Indeed, from a first analysis we can deduce that the rest values $C_N(t_1) = 0$ and $F(t_1) = 0$ of $C_N$ and $F$ respectively are realistic and don’t need any estimation. The remaining parameters are $A_{rest}$ and $K_{m,rest}$ and $\tau_{1,rest}$. Concerning $K_{m,rest}$, a sensibility study is realized in order to determine its effect on the force variation.

**A. Sensibility study of the force versus state variables**

1) **Sensibility study of the force versus $K_m$**: The force evolution is compared for $K_{m,rest}$ and different values $K_{m,rest}’$ (±30% of error) for $I = 10\,ms$, $50\,ms$ and $100\,ms$ (see Fig. 2 for $I = 10\,ms$). In the case of $I = 10\,ms$, the maximum force error is of $-0.3\%$. Following Interpulse
value, the maximum force error is obtained for $I = 100\text{ms}$ ($-1.3\%$) which means that a tolerance of $\pm 30\%$ gives force evolution with good accuracy.

2) Sensibility study of the force versus a part of $A$ and $\tau_1$ derivatives: We compare the derivative of $A$ and $\tau_1$ (Eq. (5) and Eq. (7), respectively) with the "simplified" following derivatives (we assume a maximum stimulation time of 20s):

$$\frac{dA}{dt} = \alpha_A F \quad (11)$$

$$\frac{d\tau_1}{dt} = \alpha_{\tau_1} F. \quad (12)$$

Using (Eq. (5) and Eq. (7)) and (Eq. (11) and Eq. (12)), the force error was computed in the cases of $\eta = 0.1$, 0.5 and 1 with $I = 10\text{ms, 100ms}$ (during 10 stimulation-rest periods of 2s).

The figures (Fig. 4), (Fig. 5) and (Fig. 6) represent the relative error for $A$, $\tau_1$ and $F$, respectively. The worst case is obtained for $\eta = 1, I = 100\text{ms}$ where the relative error reaches 5.4%. The figure (Fig. 7) shows the force evolution for the two cases.

From this, we can define a "simplified model" (Eq. (1), Eq. (2), Eq. (3), Eq. (4), Eq. (6), Eq. (11) and Eq. (12)). This simplified model will be used to calculate the correction term of the observer (see the following section).
B. High-gain observer synthesis for the estimation of \( A \) and \( \tau_1 \)

In this section, we design a modified version of the standard high-gain observer given in [11] taking into account the specific structure of the problem. The system defined by the force equation Eq. (2) and the fatigue model (Eq. (5) and Eq. (7)) can be rewritten as the single input-output system:

\[
\begin{align*}
\dot{x}(t) &= \beta^m(t, E_s(t))f(x(t), E_s(t)) \\
y(t) &= h(x(t)) = F(t),
\end{align*}
\]

(13)

with \( x = (F, A, \tau_1) \in \mathbb{R}^3 \), \( y \in \mathbb{R} \), \( E_s \in \mathbb{R} \).

\[
\beta = \frac{C_N}{C_N + K_m}, 0 < \beta < 1.
\]

(14)

Note that in Eq. (13), \( K_m \) is not a state variable thanks to the robustness of the solution with respect to this variable (see Sensibility study of the force versus \( f \)). The simplification allows to bypass the choice of the integer \( \beta \) by the change of variables \( \phi \) near the specific structure of the problem.

The terms of this matrix \( A \) is a symmetric positive definite matrix given by the following Lyapunov equation:

\[
\theta S_\theta(t) + A^T S_\theta(t) + S_\theta(t)A = C^T C
\]

(17)

where \( \theta \) is a tuning parameter,

\[
A = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}, C = \begin{pmatrix} 1 & 0 & 0 \end{pmatrix}.
\]

The terms of this matrix \( S_\theta \) have the following form:

\[
S_\theta(l, k) = (-1)^{l+k} \binom{l+k-2}{k-1} \theta^{-(l+k-1)} \cdot \binom{n}{k}
\]

(18)

In the particular case of the force fatique model, \( \beta(t) \) is piecewise smooth, the lack of regularity is numerically bypassed by the choice of the integer \( m \). For example, for \( I = 10ms, m = 3 \) is sufficient to estimate the whole variables. However, for \( I = 25ms, m \) must be at least equal to 5 (see observer simulations below).

C. Muscular force control

The estimation of the state variables vector is used as an initial variables vector to perform a predictive strategy (over an horizon of \( \text{HOR} \) equal interpulse intervals) to bring the mean force value \( F_{\text{mean}} \) over \( \text{HOR} \) (see procedure below) to a force reference (see [12]). The interpulse is fixed and \( \eta_i \) is the control variable.

We use a numerical integration time called \( \text{Step}_{\text{int}} \), and for a fixed horizon \( \text{HOR} \), define \( \text{Data}_F \) by:

\[
\text{Data}_F = \text{HOR} \cdot \frac{I}{\text{Step}_{\text{int}}}
\]

(19)

1) Algorithm:

1. Given \( \text{Final}_I \) (i.e., a submultiple of \( \text{Final}_I \)), \( k = 1 \)
2. \( C_N(t_k), F(t_k), \bar{A}(t_k), \bar{\tau}_i(t_k), K_m(t_k) \)
3. \( F_{\text{mean}} = \frac{1}{\text{Data}_F} \sum_{i=1}^{\text{Data}_F} F(t_k + i \ast \text{Step}_{\text{int}}, E_s) \) with:

\[
E_s = \frac{1}{\tau_c} \sum_{i=1}^{k+\text{(HOR}-1)} (\eta_i H(t_{\text{HOR}} - t_i) + R_i \exp(-\frac{t_{\text{HOR}} - t_i}{\tau_c}))
\]

and: \( \eta_i = \eta_k \) for \( i = k, k+1, ..., k + (\text{HOR}-1) \), \( t_{\text{HOR}} = (k + \text{HOR}) \times I \)
5. Compute \( \bar{A}(t), \bar{\tau}_i(t), t \in [t_k, t_{k+1}] \)
6. if \( t_{k+1} = \text{Final}_I \) stops, else, \( k = k + 1, \text{back to } 2 \)

In this case (fixed \( I \) and \( \text{HOR} \)), only \( I = 10ms(100Hz) \) is considered for the computation of the predictive control.

IV. Simulation Results

MATLAB/SIMULINK software was used to perform the different simulations with Runge-Kutta solver and an integration time \( \text{Step}_{\text{int}}0 = 1ms \). The force-fatigue model depends on six free model parameters (\( \tau_c, A, \tau_1, \tau_2, R_0, \) and \( K_m \)). The values of these parameters were computed in the case of a typical subject.

A. Observer and control simulation Results for \( \text{HOR}=10 \)

For estimation simulation, we consider the worst case of +30% of error of \( K_m \). Fig. (8) and Fig. (9) represents the \( \bar{A} \) estimates for 100Hz (\( I = 10ms \)) and 40Hz (\( I = 10ms \)), respectively. Fig. (10) and Fig. (11) are the \( \bar{\tau}_i \) estimates for 100Hz and 40Hz. \( \bar{A} \) converges after 50ms when \( I = 10ms \) and 100ms when \( I = 25ms \). Concerning \( \bar{\tau}_i \), it converges after 75ms when \( I = 10ms \) and 200ms when \( I = 25ms \). Large \( I \) seems to delay the convergence of the observer.
Fig. (12) represents the control strategy (for a prediction horizon $HOR = 10$) based on the proposed observer for $I = 25\text{ms}$ and a mean force reference of $250N$. It can be observed that the force mean value converges to the force reference after 200ms.

Fig. 12. Evolution of $F$, $\hat{F}$ and $F$ mean value over $I$ for $I = 25$, 30% error of $K_m$, $F_{ref} = 250N$

B. Control simulation results

1) Control precision following the prediction horizon:
The choice of $HOR$ in Fig. (12) is motivated by different tests (different stimulation frequencies and force reference values). Fig. (13) and Fig. (14) represent control results for ($I = 10\text{ms}$, $F_{ref} = 50N$) and ($I = 50\text{ms}$, $F_{ref} = 330N$). In these two cases, the more adequate prediction horizon is $HOR = 10$ to give short response time with a low overshoot.

Fig. 13. Evolution of $F$ for $I = 10\text{ms}$, $F_{ref} = 50N$ and different prediction horizon lengths
2) Fatigue effect: Fig. (15) and Fig. (16) are the force response and the control (pulses amplitudes) applied to bring $F_{\text{mean}}$ to 250N, respectively. It can be observed that starting from the 4th period, the pulses amplitudes saturate at 1 which means that the FES is reaching its maximum value to counteract the fatigue effect.

V. Conclusion

Our study aims to present control-observer techniques into the FES control of the force-fatigue model of Ding. The proposed observer deals with the specific case of a continuous system with a discrete control. The correction term is related to the applied interpulse. The used nonlinear MPC technique to control the force level depends on the optimum search space which is not necessary convex. Despite the fact that the found minimum could not be a global minimum, appropriate receding horizon allowed to reach the force reference. Numerical simulations validate these techniques. This work is the first step of a complete study in the frame of (closed loop) optimal control analysis of the problem.
