Body: Background: The Food Standards Agency Nutrient Profiling System (FSA-NPS) constitutes the basis for the Five-Colour Nutrition Label suggested in France to be put on the front-of-pack of food products. At the individual level, a dietary index (FSA-NPS DI) has been derived and validated and corresponds to a weighted mean of all FSA-NPS scores of foods usually consumed by the individual, reflecting the nutritional quality of his/her diet. Our aim was to investigate the association between the FSA-NPS DI and breast cancer risk in a large cohort.

Methods: This prospective study included 46,864 women aged over 35y from the NutriNet-Santé cohort (2009-2015) who completed at least three 24h dietary records during the first 2y of follow-up (median follow-up: 4.0y). 555 incident breast cancers were diagnosed. FSA-NPS DI was computed for each subject using the following nutrient content for 100g of each foods and beverages consumed: energy, total sugar, saturated fatty acid, sodium, fruits and vegetables (%), fibres and proteins. Higher values of the FSA-NPS DI correspond to a lower nutritional quality of the diet. Associations were characterized by multivariate Cox proportional hazards models.

Results: The FSA-NPS DI was directly associated with breast cancer risk ($HR_{1\text{-point increment}}=1.06$ (1.02-1.11), $P\text{-trend}=0.005$; $HR_{Q5vs.Q1}=1.52$ (1.11-2.08), $P\text{-trend}=0.002$). These associations were similar after the exclusion of cases diagnosed during the first year of follow-up.

Conclusions: In this prospective study, a higher FSA-NPS individual score was associated with an increased breast cancer risk. These results suggested that unhealthy food choices may be associated with a 52% increase in breast cancer risk (FSA-NPS DI ≥ 7.7 (Q5) vs. < 4.1 (Q1)), supporting the public health relevance of developing front-of-pack nutrition labels based on this score.
