Abstract

The lead(II) chloride [$\{N^{\wedge}N^{iPr}\}PbCl$] (**1**), where $\{N^{\wedge}N\}^{-}$ is a bulky, monoanionic, bidentate iminoanilide ligand, was synthesised by salt metathesis between [$\{N^{\wedge}N^{iPr}\}Li$] and $PbCl_2$. The complex was characterised by X-ray diffraction crystallography and ^{207}Pb NMR spectroscopy. It exists in the molecular solid-state as a monometallic three-coordinate species, with two independent, similar but not identical molecules per asymmetric unit. The differences between the first coordination sphere of **1** and that of Fulton's structurally related β -diketiminato complex [$\{N^{\wedge}N^{iPr}\}PbCl$] are illustrated. The synthesis of **1** offers a convenient handle in the still underdeveloped organometallic and inorganic chemistry of lead(II), as exemplified by the synthesis of the alkyl complex [$\{N^{\wedge}N^{iPr}\}PbCH(CH_3)_2$] (**3**). The iodo complex [$\{N^{\wedge}N^{iPr}\}PbI$] (**2**) was also synthesised but, unlike **1**, it showed limited stability in solution.

Keywords: lead(II) chloride; iminoanilide; coordination sphere; lead(II) alkyl

Introduction

Lead has been extensively used in industry, as an anti-knock additive in petrol and in metal piping, until its high toxicity has been judged prohibitive. The coordination chemistry of lead has on the other hand attracted little attention. It is only in the past two decades that bulky ancillary ligands have yielded low-coordinate lead(II) complexes, and that their reactivity have been explored. Until then, lead(II) complexes had been plagued by light sensitivity and by a propensity to decompose and form insoluble lead(0) during uncontrolled redox processes.

Major advances in lead(II) coordination chemistry were achieved with monodentate terphenyl and bidentate β -diketiminato ligands, and a number of remarkable two- and three-coordinate complexes were structurally characterised. Terphenyls have for instance yielded the encumbered two-coordinate $[\text{Pb}\{\text{Ar}'\}_2]$ (Simons et al., 1997) and $[\{\text{Ar}'\}\text{PbSi}(\text{SiMe}_3)_3]$ (Klett et al., 1999) where $\text{Ar}' = \text{C}_6\text{H}_3\text{Mes}_{2-2,6}$, the halo-bridged dimers $[\{\text{Ar}''\}\text{Pb}(\mu\text{-Br})_2]$ (Pu et al., 2000) and $[\{\text{Ar}''\}\text{Pb}(\mu\text{-I})_2]$ (Filippou et al., 2004) where $\text{Ar}'' = \text{C}_6\text{H}_3\text{Trip}_{2-2,6}$, and the two-coordinate organolead(II) compounds $[\{\text{Ar}''\}\text{PbR}]$ for $\text{R} = \text{Me}$, ^tBu or Ph (Pu et al., 2000). More recently, the groups of Fulton and Roesky have reported on monometallic lead(II) compounds stabilised by ubiquitous β -diketiminates. The halides $[\{\text{BDI}^{\text{iPr}}\}\text{PbX}]$, where $\text{X} = \text{Cl}$, Br or I , were disclosed in 2007 (Chen et al., 2007); the compounds were obtained by salt metathesis between PbX_2 and $[\{\text{BDI}^{\text{iPr}}\}\text{Li}]$. The missing halide in this family (Figure 1), $[\{\text{BDI}^{\text{iPr}}\}\text{PbF}]$, was later reported by Roesky and co-workers, upon fluorination of $[\{\text{BDI}^{\text{iPr}}\}\text{PbNMe}_2]$ with pentafluoropyridine (Jana et al., 2011). A variety of terminal aryloxides (Fulton et al., 2007), alkoxides (Tam et al., 2009), phosphides (Yao et al., 2007; Tam et al., 2012), amides and anilides (Harris et al., 2014) and alkyl (Jana et al., 2009; Taylor et al., 2015) mononuclear compounds $[\{\text{BDI}^{\text{iPr}}\}\text{PbX}]$ were also synthesised by salt metathesis reactions, most of them from the chloro complex $[\{\text{BDI}^{\text{iPr}}\}\text{PbCl}]$.

Fulton and co-workers also revealed a rare case of lead(II) cation, $[\{\text{BDI}^{\text{iPr}}\}\text{Pb}]^+.\text{[B(C}_6\text{F}_5)_4]^-$ (Taylor et al., 2011). Their preparation of $[\{\text{BDI}^{\text{Me}}\}\text{PbCl}]$ and $[\{\text{BDI}^{\text{H}}\}\text{PbCl}]$ showed that bulky isopropyl groups in *ortho* positions of the β -diketiminato, as in $\{\text{BDI}^{\text{iPr}}\}^-$, were not mandatory to obtain stable, monometallic lead(II) compounds (Tam et al., 2015). The role of mononuclear chloro complexes, in particular as precursors for salt metathesis reactions, was prominent in these studies. Finally, a case of Cl-bridged aminoanilido lead(II) dimer was reported (Vaňkátová et al, 2011), where the distances between each metal centre and the two bridging chlorides exhibited a large difference, 2.620(2) and 3.167(2) Å.

[Insert Figure 1 here]

We have used the iminoanilide $\{\text{N}^{\wedge}\text{N}^{\text{iPr}}\}^-$ to synthesise a variety of alkaline-earth complexes (Figure 1). Our interest in this ligand framework stems in particular from its structural similarities with the versatile $\{\text{BDI}^{\text{iPr}}\}^-$, although the more rigid nature of the backbone in $\{\text{N}^{\wedge}\text{N}^{\text{iPr}}\}^-$ imparts original properties to this ligand (Liu et al., 2012; Liu et al., 2013). We have also developed aminophenolato (Wang et al., 2014) and organochalcogenolato (Pop et al., 2014) lead(II) complexes as well as simple alkoxides devoid of bulky ancillary ligands (Wang et al., 2015), and shown that they were competent molecular catalysts. As part of our ongoing programme in main group chemistry, we report here on the synthesis and molecular solid-state structure of the chloro complex $[\{\text{N}^{\wedge}\text{N}^{\text{iPr}}\}\text{PbCl}]$, and on its derivatisation to $[\{\text{N}^{\wedge}\text{N}^{\text{iPr}}\}\text{Pb}^{\text{iPr}}]$.

Results and Discussion

The room temperature treatment in THF of anhydrous PbCl_2 with an equimolar amount of $\{\text{N}^{\wedge}\text{N}^{\text{iPr}}\}\text{K}$, freshly prepared by deprotonation of the proligand with potassium hydride, afforded the chloro complex $[\{\text{N}^{\wedge}\text{N}^{\text{iPr}}\}\text{PbCl}]$ (**1**) (Scheme 1). The product was isolated in 62% yield as

analytically pure orange crystals upon recrystallisation from a pentane solution. The identity of **1** was established on the basis of NMR spectroscopy and X-ray diffraction crystallography, and its purity was corroborated by combustion analysis. Pure, microcrystalline [$\{N^{\wedge}N^{iPr}\}PbI$] (**2**) was obtained in similar fashion in 31% non-optimised yield upon reaction of PbI_2 and $\{N^{\wedge}N^{iPr}\}K$. Both compounds are readily soluble in common non-protic organic solvents, including aliphatic hydrocarbons.

[Insert Scheme 1 here]

The NMR spectroscopic data for the two complexes were recorded in benzene- d_6 . The 1H NMR spectrum of complex **1** display a diagnostic singlet at 8.21 ppm for the imine $Ar-CH=N$ hydrogen, with a distinctive $^3J_{HPb}$ coupling constant of 56 Hz consistent with the binding N_{imine} to the metal. The corresponding resonance appears at 8.11 ppm in the 1H spectrum of complex **2**, which exhibits broad resonances at 298 K testifying to fluxional processes in solution. In the $^{13}C\{^1H\}$ NMR spectra, the resonances for $Ar-CH=N$ carbons atoms are detected at 167.17 and 168.22 ppm for **1** and **2**, respectively. The ^{207}Pb NMR spectra were recorded for the two complexes. No resonance could be detected for **2**, perhaps because the complex starts decomposing to unidentifiable species in solution within 3-4 hours, or perhaps owing to strong coupling to iodide ($I = 5/2$ for ^{127}I), broadening the resonance that could not be distinguished from the baseline. We note that similarly, the ^{207}Pb resonance for [$\{BDI^{iPr}\}PbI$] has to our knowledge been reported neither in the seminal paper (Chen et al., 2007) nor later. On the other hand, the ^{207}Pb resonance for **1** was detected at +1317 ppm, i.e. in the region diagnostic of three-coordinate β -diketiminato lead(II) chlorides: compare for instance with the resonances for [$\{BDI^{iPr}\}PbCl$] (+1413 ppm; Jana et al., 2009), [$\{BDI^{Me}\}PbCl$] and [$\{BDI^H\}PbCl$] (+1227 and +1388 ppm; Tam et al., 2015). The resonance for the Cl-bridged aminoanilide [$\{(2-$

$\text{Me}_2\text{NCH}_2\text{C}_6\text{H}_4\text{N}(\text{SiMe}_3)\text{Pb}(\mu\text{-Cl})_2$ was somewhat deshielded (+1816 ppm), although this may result from the different nature of the ancillary ligand rather than from the four-coordinate environment of the metal centres in this dinuclear complex (Vaňkátová et al, 2011).

The molecular solid-state structure of the chloro complex **1** was established by single crystal X-ray diffraction analysis. The asymmetric unit contains two similar, but not identical, molecules of $[\{\text{N}^{\text{iPr}}\}\text{PbCl}]$, **1a** and **1b**. The distance of the lead atom to the mean planes defined by the $\text{N}_{\text{anilide}}\text{-C-C-C}=\text{N}_{\text{imine}}$, that is, 0.53 (for **1a**) and 0.32 Å (for **1b**), is the main difference between the two independent components. The structure of **1a** is depicted in Figure 2, and only the geometric parameters for this component are discussed in detail. A summary of interatomic distances and angles data for **1a** and **1b**, showing their close similarities, is collated in Table 1.

[Insert Figure 2 here]

The chloride Cl1 sits in *endo* conformation, i.e. roughly perpendicular to the $\text{N}_{\text{anilide}}\text{-C-C-C}=\text{N}_{\text{imine}}$ plane (aka N1-C2-C7-C8-N9) as seen for other β -diketiminato Pb(II)-halides. The Pb1-Cl1 bond length (2.5912(19) Å) in **1a** compares well with those measured in Fulton's β -diketiminates $[\{\text{BDI}^{\text{iPr}}\}\text{PbCl}]$ (2.5653(7) Å) and $[\{\text{BDI}^{\text{Me}}\}\text{PbCl}]$ (2.5757(11) Å), and it is much shorter than in the polymeric $[\{\text{BDI}^{\text{H}}\}\text{PbCl}]$ (2.8081(11) and 2.9928(11) Å) (Tam et al., 2015). The Pb1-N1 distance is expectedly shorter for the negatively charged N_{amide} atom (2.246(6) Å) than the Pb1-N9 distance (2.336(6) Å) to the neutral N_{imine} atom. By comparison, the two pertaining Pb-N bonds are commensurate in β -diketiminato complexes, e.g. in $[\{\text{BDI}^{\text{iPr}}\}\text{PbCl}]$ (2.290(2) and 2.280(2) Å), in $[\{\text{BDI}^{\text{H}}\}\text{PbCl}]$ (2.279(3) and 2.285(4) Å), or in $[\{\text{BDI}^{\text{Me}}\}\text{PbCl}]$ (2.288(3) and 2.306(3) Å) (Tam et al., 2015). On the other hand, the pertaining Pb-N bonds were much longer (2.459(3) and 2.426(3) Å) in the dimeric complex $[\{\text{L}\}\text{Pb}]_2$ incorporating the dianionic N-{2-([4-

N-ethylthiose-micarbazone]methyl)phenyl}-p-toluene-sulfonamide ligand $\{L\}^-$ and featuring four-coordinate lead atoms (Pedrigo et al., 2008). The geometry about N1 and N9 is trigonal planar, with the sum of angles reaching respectively 359.9 and 359.5 °. The geometry about the lead(II) atom is pyramidal, the sum of angles amounting to 260.2 °. Note however that the angles show a certain deviation from the ideal value of 90 ° expected for three-coordinate lead(II) centres with purely $6s^2$ unpaired electrons, thus showing some contribution of the empty p_z orbital to electronic lone pair in **1a**. The degree of pyramidalisation (DoP) of the metal in **1a**, defined by $\text{DoP} = [360 - \sum_{i=1}^3 \theta(i)]/0.9$ where $\theta(i)$ are the angles around lead(II) (Maksić and Kovačević, 1999), comes to 111%, exceeding by about 10-15% those found in most chloro lead(II) β -diketiminates. However, both values are very similar to those measured in $[\{\text{BDI}^{\text{H}}\}\text{PbCl}]$ (sum of angles = 261 °, DoP = 110%) (Tam et al., 2015).

[Insert table 1 here]

The existence of two distinct molecules, **1a** and **1b**, in the asymmetric unit of the molecular structure of **1**, can be tentatively linked to the presence of close molecules **1a'** and **1b'** in the crystal lattice (but in adjacent asymmetric units). Hence, the lead atoms, Pb1 in **1a** and Pb2 in **1b**, are located at short range of the chlorides Cl1' and Cl2' from the respective neighbouring symmetry-related molecules **1a'** and **1b'**. Due to packing forces, the different distances Pb2...Cl2' (3.353 Å, see Figure 3) and Pb1...Cl1' (3.428 Å), may hence impact the respective positions of the lead atoms Pb1 and Pb2 with respect to the mean NCCCN plane. Note that these two distances are too long for a Pb-Cl bond. For instance, the Pb-Cl bond lengths in the polymeric $[\{\text{BDI}^{\text{H}}\}\text{PbCl}]$, 2.8081(11) and 2.9928(11) Å (Tam et al., 2015), were much shorter than Pb1...Cl1' and Pb2...Cl2' distances in **1a** and **1b**. On the other hand, in $[\{\text{N}(\text{SiMe}_3)\text{C}(\text{Ph})\text{C}(\text{SiMe}_3)(\text{C}_5\text{H}_4\text{N}-2)\}\text{PbCl}]$ bearing a pyridyl-1-azaallyl monoanionic ligand,

the Pb-Cl bond lengths were in the range 2.599(2)-2.641(2) Å, whereas there was no interaction between the metal atoms and chlorides situated at a greater distance, 3.086(2)-3.173(2) Å (Leung et al., 2005).

[Insert Figure 3 here]

In an attempt to prepare a lead(II) alkyl, **1** was reacted with an equimolar amount of ⁱPrMgBr. The orange microcrystalline [{N[^]N^{iPr}}PbCH(CH₃)₂(THF)] (**3**) was isolated from pentane, but X-ray quality crystals eluded us. The identity of **3** was authenticated by its NMR data recorded in benzene-*d*₆. The ¹H NMR spectrum given in Figure 4 shows the formation of the targeted product. The high field heptet at 0.01 ppm was assigned to [Pb]-CH(CH₃)₂. In the ¹³C{¹H} NMR spectrum, the metal-bound isopropyl generates resonances at 8.77 ppm for PbCH(CH₃)₂ and 25.34 ppm for PbCH(CH₃)₂. The presence of one molecule of THF that could not be removed in vacuo was detected in the ¹H and ¹³C{¹H} NMR spectra, with resonances at δ_{1H} = 3.49 and 1.14 ppm and at δ_{13C} = 69.66 and 24.82 ppm. These chemical shifts, different from those of free THF in benzene-*d*₆, suggest binding of THF to the metal. This would result in a 20-electron complex if the imine remained coordinated. The CH=N imine remains intact in **3**, as corroborated by a singlet at 7.95 ppm in the ¹H NMR spectrum and a downfield resonance at 171.48 ppm in the ¹³C{¹H} spectrum.

[Insert Figure 4 here]

Conclusion

The iminoanilido complex [{N[^]N^{iPr}}PbCl] (**1**), a useful addition to the limited number of soluble three-coordinate lead(II) chlorides, has been synthesised and structurally characterised. This complex a priori opens access upon derivatisation to a larger panel of other lead(II) complexes, as

exemplified by the preparation of a lead(II)-alkyl complex $[\{N^{\wedge}N^{iPr}\}PbCH(CH_3)_2]$ (**3**); further examples can be anticipated from the extensive work in this area by the group of Fulton. The coordination sphere of **1** shows noticeable differences with that of the analogous β -diketiminato complex $[\{BDI^{iPr}\}PbCl]$; a summary of the coordination spheres in the iminoanilido $[\{N^{\wedge}N^{iPr}\}PbCl]$ (**1**) and Fulton's congeneric β -diketiminato $[\{BDI^{iPr}\}PbCl]$ (Chen et al., 2007) is provided in Figure 5; only the most pertinent bond lengths and angles are given. In conjunction with the data obtained earlier with large alkaline earths (Liu et al., 2012; Liu et al., 2013), the results disclosed here illustrate that subtle differences of coordination patterns are to be expected when one or the other of the two structurally related ligand platforms $\{N^{\wedge}N^{iPr}\}^-$ and $\{BDI^{iPr}\}^-$ are used. This may bear substantial implications for applicative purposes, for instance in molecular catalysis where control of the first coordination sphere about the central metal takes a prominent role.

Experimental Section

General procedures

All manipulations were performed under inert atmosphere using standard Schlenk techniques or in a dry, solvent-free glove-box (Jacomex; $O_2 < 1$ ppm, $H_2O < 5$ ppm) for catalyst loading. Solvents (THF, Et_2O , CH_2Cl_2 , pentane and toluene) were purified and dried (water contents below 8 ppm) over alumina columns (MBraun SPS). THF was further distilled under argon from sodium/benzophenone ketyl. All deuterated solvents (Eurisotop, Saclay, France) were stored in sealed ampoules over activated 3 Å molecular sieves and were thoroughly degassed by several freeze-thaw-vacuum cycles. $PbCl_2$ and PbI_2 were purchased from Strem and used as received.

ⁱPrMgBr (1.0 M solution in THF) was bought from Aldrich. {N[^]N^{iPr}}H (Hayes et al., 2003) was synthesised according to literature procedures.

NMR spectra were recorded on Bruker AM-400 and AM-500 spectrometers. All ¹H and ¹³C{¹H} chemicals shifts were determined using residual signals of the deuterated solvents and were calibrated vs. SiMe₄. Assignment of the signals was carried out using 1D (¹H, ¹³C{¹H}) and 2D (COSY, HMBC, HMQC) NMR experiments. ²⁰⁷Pb NMR spectra were referenced externally against a solution of [Pb[N(SiMe₃)₂]₂] in benzene-*d*₆ (δ_{207Pb} = +4916 ppm).

Elemental analyses were performed on a Carlo Erba 1108 Elemental Analyser instrument at the London Metropolitan University by Stephen Boyer and were the average of two independent measurements.

[{N[^]N^{iPr}}K]: {N[^]N^{iPr}}H (1.00 g, 2.27 mmol) was dissolved in toluene (50 mL). KH (0.10 g, 2.50 mmol) was added in fractions using a bent finger. The reaction mixture was heated at 80 °C overnight. The solution was then cooled to room temperature, filtered to remove insoluble materials, and the solvent was pumped off under vacuum. Following washing with pentane (3×5 mL), {N[^]N^{iPr}}K was isolated as an orange powder (1.0 g, 92%). The spectroscopic and analytical data for this product matched those described in the literature (Kloek and Goldberg, 2007).

[{N[^]N^{iPr}}PbCl] (1): Anhydrous PbCl₂ (0.41 g, 1.47 mmol) was suspended in THF (10 mL). [{N[^]N^{iPr}}K] (0.92 g, 1.47 mmol) was dissolved in THF (10 mL) and the solution was added dropwise with a cannula to the solution of PbCl₂ at room temperature. The reaction mixture was stirred for 12 h, during which a white precipitate gradually appeared. The precipitate was eliminated by filtration and the solvent was pumped off under vacuum. Complex **1** was extracted with pentane (3 × 5 mL) and isolated as orange crystals (0.63 g, 62%) by crystallisation at –27 °C. Single crystals suitable for X-ray diffraction studies were selected from this batch. ¹H NMR

(benzene-*d*₆, 400.1 MHz, 298 K): δ 8.21 (t, 1H, CH=N, $^3J_{\text{HPb}} = 56$ Hz), 7.31 (d, $^3J_{\text{HH}} = 7.4$ Hz, 3H, arom-*H*), 7.13 (m, 1H, arom-*H*), 7.02 (m, 4H, arom-*H*), 6.41 (m, 1H, arom-*H*), 6.24 (m, 1H, arom-*H*), 3.93 (hept, $^3J_{\text{HH}} = 6.4$ Hz, 2H, CH(CH₃)₂), 3.27 (hept, $^3J_{\text{HH}} = 6.2$ Hz, 1H, CH(CH₃)₂), 3.05 (hept, $^3J_{\text{HH}} = 6.2$ Hz, 1H, CH(CH₃)₂), 1.50 (overlapping m, 6H, CH(CH₃)₂), 1.15 (overlapping m, 12H, CH(CH₃)₂), 0.99 (br, 6H, CH(CH₃)₂) ppm. ¹³C{¹H} NMR (benzene-*d*₆, 125.8 MHz, 298 K): δ 167.17 (CH=N), 157.93 (N=CH-*i*-C₆H₄), 152.00 (ArN-*i*-C₆H₃), 151.47 (CH=N-*i*-C₆H₃), 147.86 (N-*i*-C₆H₄), 141.85 (ArN-*o*-C₆H₃), 139.5 (N=CH-*o*-C₆H₄), 132.36 (N-*o*-C₆H₄), 124.35 (CH=N-*o*-C₆H₃), 123.90 (ArN-*m*-C₆H₃), 123.14 (CH=N-*m*-C₆H₃), 121.21 (N=CH-*m*-C₆H₄), 117.23 (CH=N-*p*-C₆H₃), 116.48 (ArN-*p*-C₆H₃), 107.44 (N=CH-*p*-C₆H₄), 29.01 (CH(CH₃)₂), 28.59 (CH(CH₃)₂), 28.13 (br, CH(CH₃)₂), 27.83 (br, CH(CH₃)₂), 24.83 (CH(CH₃)₂), 24.45 (br, CH(CH₃)₂), 24.30 (br, CH(CH₃)₂), 23.79 (CH(CH₃)₂) ppm. ²⁰⁷Pb NMR (benzene-*d*₆, 83.97 MHz, 298 K): $\delta = 1317$ ppm. Elemental analysis for C₃₁H₃₉ClN₂Pb (682.32 g.mol⁻¹): theoretical, C 54.57%, H 5.76%, N 4.11%; found C 54.6%, H 5.9%, N 3.9%.

[{N[^]N^{iPr}}PbI] (2): Anhydrous PbI₂ (0.48 g, 1.05 mmol) was suspended in THF (10 mL). {N[^]N^{iPr}}K (0.50 g, 1.05 mmol) was dissolved in THF (10 mL) and the solution was added dropwise with a cannula to the solution of PbI₂ at room temperature. The reaction mixture was stirred for 12 h, and a white precipitate formed gradually. The precipitate was removed by filtration, and the solvent was pumped off under vacuum. The product was extracted with pentane (3 × 5 mL) and isolated as an analytically pure orange solid (0.25 g, 31%) following precipitation at -27 °C. Note that the complex started decomposing within ca. 3-4 h in solution, which precluded the recording of reliable ¹³C{¹H} NMR data. ¹H NMR (benzene-*d*₆, 400.1 MHz, 298 K): δ 8.11 (s, 1H, CH=N), 7.22 (m, 4H, arom-*H*), 7.13 (m, 3H, arom-*H*), 7.08 (m, 1H, arom-*H*), 6.41 (d, $^3J_{\text{HH}} = 8.8$ Hz, 1H, arom-*H*), 6.24 (t, $^3J_{\text{HH}} = 7.3$ Hz, 1H, arom-*H*), 3.97 (br, 2H,

$\text{CH}(\text{CH}_3)_2$), 3.27 (br, 1H, $\text{CH}(\text{CH}_3)_2$), 3.11 (br, 1H, $\text{CH}(\text{CH}_3)_2$), 1.50 (br, 6H, $\text{CH}(\text{CH}_3)_2$), 1.19 (d, $^3J_{\text{HH}} = 6.9$ Hz, 12H, $\text{CH}(\text{CH}_3)_2$), 0.97 (br, 6H, $\text{CH}(\text{CH}_3)_2$) ppm. $^{13}\text{C}\{^1\text{H}\}$ NMR (benzene- d_6 , 125.8 MHz, 298 K): δ 168.22 (CH=N) ppm; the recording of other reliable $^{13}\text{C}\{^1\text{H}\}$ NMR data was precluded by the instability of the complex in solution. No resonance could be detected in the ^{207}Pb NMR spectrum of this complex. Elemental analysis for $\text{C}_{31}\text{H}_{39}\text{IN}_2\text{Pb}$ (773.77 g.mol $^{-1}$): theoretical, C 48.12%, H 5.08%, N 3.62%; found C 48.2%, H 5.2%, N 3.8%.

[{N^{^i}Pr}PbCH(CH₃)₂·THF] (3): Compound **1** (0.20 g, 0.29 mmol) was dissolved in toluene (10 mL) and cooled to -80 °C. A 1.0 M solution of $^i\text{PrMgBr}$ in THF (0.29 mL, 0.29 mmol) was slowly syringed in the reaction mixture, causing a rapid change of colour. The resulting orange solution was stirred for 2 h at -80 °C. Toluene was then pumped off under vacuum. The product was extracted with pentane (3×5 mL) and isolated as an orange microcrystalline material (50 mg, 25%; yield not optimised) by crystallisation at -27 °C. ^1H NMR (benzene- d_6 , 400.1 MHz, 298 K): δ 7.95 (s, 1H, CH=N), 7.31 (m, 3H, arom-*H*), 7.15 (m, 3H, arom-*H*), 6.94 (d, $^3J_{\text{HH}} = 6.2$ Hz, 1H, arom-*H*), 6.83 (m, 1H, arom-*H*), 6.42 (d, $^3J_{\text{HH}} = 8.4$ Hz, 1H, arom-*H*), 6.25 (m, 1H, arom-*H*), 3.49 (br, 4H, OCH_2CH_2), 3.37 (br, 2H, $\text{CH}(\text{CH}_3)_2$), 3.18 (br, 2H, $\text{CH}(\text{CH}_3)_2$), 1.40-1.05 (several overlapping m, 30H, $\text{CH}(\text{CH}_3)_2$), 1.14 (m, 4H, OCH_2CH_2), 0.01 (hept, $^3J_{\text{HH}} = 7.8$ Hz, 1H, $\text{PbCH}(\text{CH}_3)_2$) ppm. $^{13}\text{C}\{^1\text{H}\}$ NMR (benzene- d_6 , 125.8 MHz, 298 K): δ 171.48 (CH=N), 160.83 (N=CH-*i*-C₆H₄), 148.35 (ArN-*i*-C₆H₃), 146.49 (CH=N-*i*-C₆H₃), 144.31 (N-*i*-C₆H₄), 141.35 (br, N=CH-*p*-C₆H₄), 138.20 (ArN-*o*-C₆H₃), 133.70 (N=CH-*o*-C₆H₄), 126.54 (N-*o*-C₆H₄), 125.04 (CH=N-*o*-C₆H₃), 124.44 (br, ArN-*m*-C₆H₃), 123.95 (CH=N-*m*-C₆H₃), 119.12 (N=CH-*m*-C₆H₄), 116.13 (CH=N-*p*-C₆H₃), 112.08 (ArN-*p*-C₆H₃), 69.66 (OCH_2CH_2), 28.48 (ArCH(CH₃)₂), 28.46 (ArCH(CH₃)₂), 25.65 (ArCH(CH₃)₂), 25.50 (ArCH(CH₃)₂), 25.46 (ArCH(CH₃)₂), 25.34 (PbCH(CH₃)₂), 24.82 (OCH_2CH_2), 23.34 (ArCH(CH₃)₂), 8.77 (PbCH(CH₃)₂) ppm. Elemental

analysis for $C_{38}H_{54}N_2OPb$ ($762.06 \text{ g.mol}^{-1}$): theoretical, C 59.89%, H 7.14%, N 3.68%; found C 61.7%, H 7.2%, N 3.3%.

X-ray diffraction crystallography

Crystals of $[N^iPrN]PbCl$ (**1**) suitable for X-ray diffraction analysis were obtained by recrystallisation of the purified compound. Diffraction data were collected at 150(2) K using a Bruker APEX CCD diffractometer with graphite-monochromated $MoK\alpha$ radiation ($\lambda = 0.71073 \text{ \AA}$). A combination of ω and Φ scans was carried out to obtain at least a unique data set. The crystal structures were solved by direct methods, remaining atoms were located from difference Fourier synthesis followed by full-matrix least-squares refinement based on F2 (programs SIR97 and SHELXL-97) (Sheldrick, 1997a; Sheldrick, 1997b). Carbon- and oxygen-bound hydrogen atoms were placed at calculated positions and forced to ride on the attached atom. All non-hydrogen atoms were refined with anisotropic displacement parameters. The locations of the largest peaks in the final difference Fourier map calculation as well as the magnitude of the residual electron densities were of no chemical significance. Relevant collection and refinement data are collated in Table 1. Crystal data, details of data collection and structure refinement for **1** (CCDC n° 1559881) can be obtained free of charge from the Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Table 1: Comparison of interatomic distances and angles in the two similar but independent molecules **1a** and **1b** in the molecular solid-state structure of $[\{N^{\wedge}N^{iPr}\}Pb(\mu-Cl)]$ (**1**).

Molecule	1a	1b
Pb atom	Pb1	Pb2
<i>Interatomic distances</i>		
Pb-Cl	2.5912(19) Å	2.574(2) Å
Pb-N _{amide}	2.246(6) Å	2.249(6) Å
Pb-N _{imine}	2.336(6) Å	2.361(6) Å
Pb-NCCCN _{plane}	0.535 Å	0.318 Å
<i>Angles</i>		
∠ Cl-Pb-N _{amide}	94.61(16) °	96.17(16) °
∠ Cl-Pb-N _{imine}	84.98(15) °	85.16(15) °
∠ N _{amide} -Pb- Pb-N _{imine}	80.60(2) °	80.70(2) °
Sum of Pb angles	260.2 °	262.0 °
DoP (%)	111%	109%
Sum of N _{amide} angles	359.9 °	359.0 °
Sum of N _{imine} angles	359.5 °	359.3 °

Table 2: Summary of crystallographic data for [$\{N^{\wedge}N^{iPr}\}Pb(\mu-Cl)$] (**1**, CCDC n° 1559881)

Formula	$C_{62} H_{78} Cl_2 N_4 Pb_2$
Mol. wt.	1364.56
Crystal system	Triclinic
Space group	$P -1$
$a(\text{\AA})$	13.9011(9)
$b(\text{\AA})$	14.5332(13)
$c(\text{\AA})$	16.6762(12)

$\beta(^{\circ})$	67.490(3)
$\gamma(^{\circ})$	69.554(2)
$V(\text{\AA}^3)$	2883.7(4)
Z	2
Density (g.cm^{-3})	1.572
Abs. coeff., (mm^{-1})	5.964
$F(000)$	1352
Crystal size, mm	$0.60 \times 0.59 \times 0.58$
θ range (deg)	2.96 to 27.48
Limiting indices	$-18 < h < 17$ $-18 < k < 18$ $-21 < l < 21$
$R(\text{int})$	0.0628
Reflections collected	27332
Reflec. Unique [$I > 2\sigma(I)$]	12970
Completeness to θ (%)	98.2
Data/restraints/param.	12970 / 0 / 629
Goodness-of-fit	0.986
R_1 [$I > 2\sigma(I)$] (all data)	0.0524 (0.0820)
wR_2 [$I > 2\sigma(I)$] (all data)	0.1173 (0.1302)
Largest diff. ($\text{e.\AA}^{-3}$)	3.622 and -4.134

Figure 1: Three-coordinate mononuclear lead(II) halides and their proligands.

Scheme 1: Syntheses of $[\{\text{N}^{\wedge}\text{N}^{\text{iPr}}\}\text{PbCl}]$ (**1**) and $[\{\text{N}^{\wedge}\text{N}^{\text{iPr}}\}\text{PbI}]$ (**2**).

Figure 2: Molecular solid-state structure of one of the two independent components (**1a**) in $[\{N^{\wedge}N^{iPr}\}PbCl]$ (**1**). H atoms are omitted for clarity. Selected interatomic distances (Å) and angles (deg): Pb1-N1 = 2.246(6), Pb1-N9 = 2.336(6), Pb1-Cl1 = 2.5912(19), N1-C2 = 1.357(9), N1-C10 = 1.449(9), C2-C7 = 1.434(10), C7-C8 = 1.421(9), C8-N9 = 1.309(9), N9-C22 = 1.434(9); N1-Pb1-N9 = 80.60(2), N1-Pb1-Cl1 = 94.60(16), N9-Pb1-Cl1 = 84.98(15), C2-N1-C10 = 119.50(6), C2-N1-Pb1 = 131.80(5), C10-N1-Pb1 = 108.60(4), C8-N9-C22 = 118.60(6), C8-N9-Pb1 = 125.20(5), C22-N9-Pb1 = 115.70(4). Pb1 sits 0.53 Å above the N1-C2-C7-C8-N9 mean plane.

Figure 3: Representation of the molecular solid-state structure of one of the two independent components (**1b**) in $[\{N^{\wedge}N^{iPr}\}PbCl]$ (**1**), showing the short $Pb2 \cdots Cl2'$ and $Pb2' \cdots Cl2$ distances with the symmetry-related **1b'**. Selected interatomic distances (Å) and angles (deg): $Pb2-Cl2 = 2.574(2)$, $Pb2-Cl2' = 3.353(2)$; $Cl2-Pb2-Cl2' = 78.09(6)$. See table 1 for other key parameters.

Figure 4: ^1H NMR spectrum ($\text{benzene-}d_6$, 400 MHz, 298 K) of $[\{\text{N}^{\text{N}^{\text{iPr}}}\}\text{Pb}^{\text{iPr}}]$ (**3**). † = silicone grease. ‡ = residual pentane.

Figure 5: Comparison of interatomic distances (given in Å) and angles between $[\{N^{\wedge}N^{iPr}\}PbCl]$ (**1**) and Fulton's directly related $[\{BDI^{iPr}\}PbCl]$ (Chen et al., 2007). Average values for the two independent components **1a** and **1b** are given for complex **1**.
