Spectral Convergence of Large Block-Hankel Gaussian Random Matrices

Philippe Loubaton and Xavier Mestre

Dedicated to Prof. Daniel Alpay on occasion of his 60th birthday

Abstract. This paper studies the behaviour of the empirical eigenvalue distribution of large random matrices $W_N W_N^H$ where $W_N$ is a $ML \times N$ matrix, whose $M$ block lines of dimensions $L \times N$ are mutually independent Hankel matrices constructed from complex Gaussian correlated stationary random sequences. In the asymptotic regime where $M \to +\infty$, $N \to +\infty$ and $\frac{ML}{N} \to c > 0$, it is shown using the Stieltjes transform approach that the empirical eigenvalue distribution of $W_N W_N^H$ has a deterministic behaviour which is characterized.

Mathematics Subject Classification (2000). Primary 60B20; Secondary 15B52.

Keywords. Large random matrices, Stieltjes transform of positive matrix-valued measures, Hankel matrices.

1. Introduction

1.1. The addressed problem and summary of the main results.

In this paper, we consider a $ML \times N$ block-Hankel matrix $W_N$ composed of $M$ Hankel matrices gathered on top of each other, namely

$$W_N = \begin{bmatrix} W_{1,N}^T & \cdots & W_{M,N}^T \end{bmatrix}^T.$$  

For each $m = 1, \ldots, M$, $W_{m,N}$ is a Hankel matrix of dimensions $L \times N$, with $(i,j)$th entry equal to

$$\{W_{m,N}\}_{i,j} = w_{m,N}(i + j - 1)$$

for $1 \leq i \leq L$, $1 \leq j \leq N$, where the random variables $(w_{m,N}(n))_{m=1,\ldots,M, n=1,\ldots,N+L-1}$ are zero mean complex Gaussian random variables. The different blocks $W_{m,N}$

This work was supported by the Labex Bézout under grant ANR-10-LABX-0058.
Philippe Loubaton and Xavier Mestre

are independent, but we allow for some time invariant correlation structure within each Hankel matrix, namely

$$
\mathbb{E} \left[ w_{m,N}(k) w_{m',N}^*(k') \right] = \frac{r_m(k-k')}{N} \delta_{m-m'}
$$

where $r_m(k), k \in \mathbb{Z}$, is a sequence of correlation coefficients defined as

$$
r_m(k) = \int_0^1 S_m(\nu) e^{2i\pi k\nu} d\nu
$$

where $(S_m)_{m=1,\ldots,M}$ are positive functions. We denote by $(\lambda_{k,N})_{k=1,\ldots,ML}$ the eigenvalues of random matrix $W_N W_N^H$, where $(\cdot)^H$ stands for transpose conjugate.

The purpose of this paper is to study the asymptotic properties of the empirical eigenvalue distribution

$$
\hat{d}_{\mu_N}(\lambda) = \frac{1}{ML} \sum_{k=1}^{ML} \delta_{\lambda - \lambda_{k,N}}
$$

of $W_N W_N^H$ when $M \to +\infty$, $N \to +\infty$ and $L$ is such that $c_N = \frac{ML}{N}$ converges towards a non zero constant $c > 0$.

It is well established that the asymptotic behaviour of the empirical eigenvalue distribution of large Hermitian matrices can be evaluated by studying the behaviour of their Stieltjes transforms. In the context of the present paper, the Stieltjes transform of $d_{\mu_N}(\lambda)$ is the function $q_N(z)$ defined on $\mathbb{C} \setminus \mathbb{R}^+$ by

$$
q_N(z) = \frac{1}{\lambda - z} d_{\mu_N}(\lambda) = \frac{1}{ML} \sum_{k=1}^{ML} \frac{1}{\lambda - \lambda_{k,N} - z}
$$

and also coincides with $q_N(z) = \frac{1}{ML} \text{tr} Q_N(z)$ where $Q_N(z)$ is the resolvent of matrix $W_N W_N^H$ defined by

$$
Q_N(z) = (W_N W_N^H - zI)^{-1}
$$

We denote by $S_{ML}(\mathbb{R}^+)$ the set of all $ML \times ML$ matrix valued functions defined on $\mathbb{C} \setminus \mathbb{R}^+$ by

$$
S_{ML}(\mathbb{R}^+) = \left\{ \left. \int_{\mathbb{R}^+} \frac{1}{\lambda - z} d\mu(\lambda) \right| \mu \text{ is a positive } ML \times ML \text{ matrix-valued measure carried by } \mathbb{R}^+ \right\}
$$

where $\mu$ is a positive $ML \times ML$ matrix-valued measure carried by $\mathbb{R}^+$ satisfying $\mu(\mathbb{R}^+) = I_{ML}$. In this paper, we establish that there exists a function $T_N(z)$ of $S_{ML}(\mathbb{R}^+)$, defined as the unique element of $S_{ML}(\mathbb{R}^+)$ satisfying a certain functional equation, that verifies

$$
\frac{1}{ML} \text{tr} \left( (Q_N(z) - T_N(z)) A_N \right) \to 0 \quad (1.1)
$$

almost surely for each $z \in \mathbb{C} \setminus \mathbb{R}^+$, where $(A_N)_{N \geq 1}$ is an arbitrary sequence of deterministic $ML \times ML$ matrices satisfying $\sup_N \|A_N\| < +\infty$. Particularized to the case where $A_N = I$, this property implies that

$$
q_N(z) - t_N(z) \to 0 \quad (1.2)
$$

almost surely for each $z \in \mathbb{C} \setminus \mathbb{R}^+$, where $t_N(z) = \frac{1}{ML} \text{tr}(T_N(z))$ is the Stieltjes transform of the probability measure $\mu_N = \frac{1}{ML} \text{tr}(\mu_N)$. In the present context,
this turns out to imply that almost surely, for each bounded continuous function \( \phi \) defined on \( \mathbb{R}^+ \), it holds that

\[
\frac{1}{ML} \sum_{k=1}^{ML} \phi(\hat{\lambda}_{k,N}) - \int_{\mathbb{R}^+} \phi(\lambda) \, d\mu_N(\lambda) \to 0. 
\] (1.3)

It is also useful to study the respective rates of convergence towards 0 of the variance and of the mean of

\[
\frac{1}{ML} \sum_{k=1}^{ML} \phi(\hat{\lambda}_{k,N}) - \int_{\mathbb{R}^+} \phi(\lambda) \, d\mu_N(\lambda)
\]

when \( \phi \) is a smooth function. For this, it appears sufficient to restrict to the case \( \phi(\lambda) = \frac{1}{\lambda} \) where \( z \in \mathbb{C} \setminus \mathbb{R}^+ \), i.e. to study the rate of convergence of \( \text{var}(q_N(z)) = E|(q_N(z)) - E(q_N(z))|^2 \) and of \( E(q_N(z)) - \int_{\mathbb{R}^+} \phi(\lambda) \, d\mu_N(\lambda) \). More generally, if \( (A_N)_{N \geq 1} \) is any sequence of deterministic \( ML \times ML \) matrices satisfying \( \sup_N \|A_N\| < +\infty \), we establish that

\[
\text{var} \left[ \frac{1}{ML} \text{tr} (Q_N(z)A_N) \right] = O \left( \frac{1}{MN} \right) 
\] (1.4)

and that, provided \( \frac{L^{3/2}}{MN} \to 0, \)

\[
\frac{1}{ML} \text{tr} \left( (E(Q_N(z)) - T_N(z))A_N \right) = O \left( \frac{L}{MN} \right) 
\] (1.5)

for each \( z \in \mathbb{C} \setminus \mathbb{R}^+ \).

In this paper, we concentrate on the characterization of the asymptotic behaviour of the terms \( \frac{1}{ML} \text{tr} (Q_N(z)A_N) \), and do not discuss on the behaviour of general linear statistics \( \frac{1}{ML} \sum_{k=1}^{ML} \phi(\hat{\lambda}_{k,N}) \) of the eigenvalues. In order to establish our results, we follow the general approach introduced in [14] and developed in more general contexts in [15]. This approach takes benefit of the Gaussianity of the random variables \( w_m(n) \), and use the Poincaré-Nash inequality to evaluate the variance of various terms and the integration by parts formula to evaluate approximations of matrix \( E(Q_N(z)) \).

Apart large random matrix methods, the properties of Stieltjes transforms of positive matrix valued measures play a crucial role in this paper. The first author (in the alphabetic order) of this paper had the chance to learn these tools from Prof. D. Alpay at the occasion of past collaborations. The authors are thus delighted to dedicate this paper to Prof. D. Alpay on occasion of his 60th birthday.

1.2. Motivations

The present paper is motivated by the problem of testing whether \( M \) complex Gaussian zero mean times series \( (x_m(n))_{n \in \mathbb{Z}} \) are mutually independent. For each \( m = 1, \ldots, M \), \( x_m \) is observed from time \( n = 1 \) to \( n = N \), and a relevant statistics depending on \( (x_m(n))_{n=1,\ldots,N} \) has to be designed and studied. A reasonable approach can be drawn by noting that if the \( M \) time series are independent, then, for each integer \( L \), the covariance matrix \( R_L \) of \( ML \)-dimensional random vector \( x_L(n) = (x_1(n), \ldots, x_1(n+L-1), x_2(n), \ldots, x_2(n+L-1), \ldots, x_M(n), \ldots, x_M(n+L-1)) \)
Let $x_1, \ldots, x_M$ be a sequence of $M$ i.i.d. variables. We consider the test statistic
\[ \kappa_N = \frac{1}{ML} \left( \log \det(R_L) - \sum_{m=1}^{M} \log \det(R_L^{m,m}) \right) = 0 \]
(1.6)
where $R_L^{m,m}$ represents the $m$-th $L \times L$ diagonal block of $R_L$. Therefore, it seems relevant to approximate matrix $R_L$ by the standard estimator $\hat{R}_L$ defined by
\[ \hat{R}_L = \frac{1}{ML} \sum_{n=1}^{N} x_L(n)(x_L(n))^H \]
so that we can evaluate the term $\hat{\kappa}_N$, obtained by replacing $R_L$ by $\hat{R}_L$ in (1.6), and compare it to 0. The present paper is motivated by the study of this particular test under the hypothesis that the series $(x_m)_{m=1, \ldots, M}$ are uncorrelated and assuming that $M$ and $N$ are both large. In this context, a crucial problem is to choose parameter $L$. On one hand, $L$ should be chosen in such a way that $ML/N << 1$ in order to make the estimation error $\|R_L - \hat{R}_L\|_F$ reasonably low, and thus $\hat{\kappa}_N$ close to 0 under the uncorrelation hypothesis. On the other hand, choosing a small value for $L$ is not satisfying because comparing $\hat{\kappa}_N$ to 0 allows to test that $E(x_m(l)x_{m'}(l')) = 0$ for each $(m, m')$ only for $l, l' \in \{0, \ldots, L - 1\}$, a property that does not imply formally that the time series $x_m$ and $x_{m'}$ are independent.

Therefore, choosing $L$ as large as possible is relevant. In this case, the ratio $\frac{ML}{N}$ may no longer be very small, and $\hat{\kappa}_N$ may not converge towards 0. It is thus of fundamental interest to evaluate the behaviour of $\hat{\kappa}_N$ when $M$ and $N$ are large and that $\frac{ML}{N}$ is not negligible. This question is connected to the problem addressed in the present paper because the following results potentially allow to establish that $\frac{1}{ML} \log \det(\hat{R}_L)$ has a deterministic behaviour that can be characterized. This term can indeed be written as
\[ \frac{1}{ML} \log \det(\hat{R}_L) = \frac{1}{ML} \sum_{k=1}^{ML} \phi(\hat{\lambda}_{k,N}) \]
where $(\hat{\lambda}_{k,N})_{k=1, \ldots, ML}$ are the eigenvalues of $\hat{R}_L$ and where $\phi(\lambda) = \log \lambda$. Moreover, if we denote by $w_{m,N}(n)$ the random variable $w_{m,N}(n) = \frac{1}{\sqrt{N}} x_m(n)$, then it is easily seen that matrix $\hat{R}_L$ coincides with matrix $W_N W_N^H$ where $W_N$ is constructed from the $w_{m,N}(n)$ as above, up to end effects (because matrix $W_N$ depends on random variables $(w_m(N+l))_{m=1, \ldots, M, l=1, \ldots, L-1}$ while matrix $R_L$ does not depend on these entries). However, these end effects can be shown to be negligible. Therefore, the asymptotic behaviour of $\frac{1}{ML} \log \det(\hat{R}_L)$ appears to be a consequence of the results of the present paper. We finally mention that under some reasonable assumptions, $\|R_L^{m,m} - \hat{R}_L^{m,m}\|_F \to 0$ so that it holds that
\[ \frac{1}{ML} \sum_{m=1}^{M} \log \det(\hat{R}_L^{m,m}) - \frac{1}{ML} \sum_{m=1}^{M} \log \det(R_L^{m,m}) \to 0 \]
In summary, the asymptotic behaviour of $\hat{\kappa}_N$ appears to be a consequence the study of the empirical eigenvalue distribution of $W_N W_N^H$ in the asymptotic regime where $M, N \to +\infty$ in such a way that $\frac{ML}{N}$ converges towards a non zero constant.

1.3. On the literature.

The study of the asymptotic behaviour of large random Gram matrices has a long history. Since the pioneering work of Marcenko-Pastur in 1967 ([13]), a number of random matrix models have been considered (see e.g. [2], [15] and the references therein). In the following, we mention the previous works that are connected to the present paper. As matrix $W_N$ is a block line matrix with $L \times N$ blocks, we mention the works of Girko ([7], chapter 16) as well as [4] devoted to the case where the blocks are i.i.d. We however mention that [7] and [4] did not characterize the rates of convergence and that the techniques used in these works do not allow to address the case where $L \to +\infty$. The works devoted to Hankel matrices are also relevant. [3] addressed the case where $M = 1$ and $N, L \to +\infty$ at the same rate, except that in [3], the random variables $w_{1,N}(n)$ are forced to 0 for $N < n \leq N + L - 1$. Using the moments method, [3] showed that the empirical eigenvalue distribution of $W_N W_N^*$ converges towards a non compactly supported limit distribution. The random matrix model considered in [12] is similar to matrix $W_N$ of the present paper, except that in [12], for each $m = 1, \ldots, M$, the random variables $(w_m(n))$ are uncorrelated, i.e. the spectral densities $(S_m(\nu))_{m=1,\ldots,M}$ are reduced to $S_m(\nu) = 1$ for each $\nu$. Using the Poincaré-Nash inequality and the integration by parts formula, [12] studied the asymptotic behaviour of the empirical eigenvalue distribution $\hat{\mu}_N$ in the asymptotic regime $M, N \to +\infty$ and $\frac{ML}{N} \to c$, $c > 0$. It was established that function $t_N(z)$ defined in (1.2) coincides with the Stieltjes transform of the Marcenko-Pastur distribution with parameter $c_N$, so that $\hat{\mu}_N$ converges weakly almost surely towards the Marcenko pastur distribution. The rates of convergence of the variance and of the expectation of $q_N(z) - t_N(z)$ are both characterized. Finally, [12] proved that provided $L = O(N^\alpha)$ with $\alpha < 2/3$, then the extreme non zero eigenvalues of $W_N W_N^*$ converge almost surely towards the end points of the support of the Marcenko-Pastur distribution. Therefore, the present paper is a partial generalization of [12].

1.4. Assumptions, general notations, and background on Stieltjes transforms of positive matrix valued measures.

Assumptions on $L, M, N$

Assumption 1.1. • All along the paper, we assume that $L, M, N$ satisfy $M \to +\infty, N \to +\infty$ in such a way that $c_N = \frac{ML}{N} \to c$, where $0 < c < +\infty$. In order to shorten the notations, $N \to +\infty$ should be understood as the above asymptotic regime.

• In section 6 $L, M, N$ also satisfy $\frac{L^{3/2}}{MN} \to 0$ or equivalently $\frac{L}{M^{1/2}} \to 0$. 

Assumptions on sequences \((r_m)_{m=1, \ldots, M}\) and spectral densities \((S_m)_{m=1, \ldots, M}\).

We assume that sequences \((r_m)_{m=1, \ldots, M}\) satisfy the condition

\[
\sup_M \sum_{n \in \mathbb{Z}} \left( \frac{1}{M} \sum_{m=1}^{M} |r_m(n)|^2 \right)^{1/2} < +\infty. \tag{1.7}
\]

As it holds that \(\left( \frac{1}{M} \sum_{m=1}^{M} |r_m(n)|^2 \right)^{1} \leq \frac{1}{M} \sum_{m=1}^{M} |r_m(n)|^2\), condition (1.7) implies that

\[
\sup_M \frac{1}{M} \sum_{m=1}^{M} \sum_{n \in \mathbb{Z}} |r_m(n)| < +\infty
\]

and that for each \(m\), \(\sum_{n \in \mathbb{Z}} |r_m(n)| < +\infty\). Therefore, each spectral density \(S_m\) is continuous. We also assume that

\[
\sup_M \sup_{m=1, \ldots, M} \max_{\nu \in [0, 1]} S_m(\nu) < +\infty \tag{1.8}
\]

\[
\inf_M \inf_{m=1, \ldots, M} \min_{\nu \in [0, 1]} S_m(\nu) > 0. \tag{1.9}
\]

In the following, we denote by \(R(k)\) the diagonal matrix

\[
R(k) = \text{diag}(r_1(k), \ldots, r_M(k)). \tag{1.10}
\]

General notations.

In the following, we will often drop the index \(N\), and will denote \(W_N, Q_N, \ldots\) by \(W, Q, \ldots\) in order to simplify the notations. The \(N\) columns of matrix \(W\) are denoted \((w_j)_{j=1, \ldots, N}\). For \(1 \leq l \leq L\), \(1 \leq m \leq M\), and \(1 \leq j \leq N\), \(W^m_{i,j}\) represents the entry \((i + (m-1)L, j)\) of matrix \(W\).

If \(A\) is a \(ML \times ML\) matrix, we denote by \(A^{m_1, m_2}_{i_1, i_2}\) the entry \((i_1 + (m_1 - 1)L, i_2 + (m_2 - 1)L)\) of matrix \(A\), while \(A^{m_1, m_2}\) represents the \(L \times L\) matrix \((A^{m_1, m_2}_{i_1, i_2})_{1 \leq (i_1, i_2) \leq L}\).

\(\mathbb{C}^+\) denotes the set of complex numbers with strictly positive imaginary parts. The conjugate of a complex number \(z\) is denoted \(z^*\). If \(z \in \mathbb{C} \setminus \mathbb{R}^+\), we denote by \(\delta_z\) the term

\[
\delta_z = \text{dist}(z, \mathbb{R}^+). \tag{1.11}
\]

The conjugate transpose of a matrix \(A\) is denoted \(A^H\) while the conjugate of \(A\) (i.e. the matrix whose entries are the conjugates of the entries of \(A\)) is denoted \(A^*\).

\(\|A\|\) represents the spectral norm of matrix \(A\). If \(A\) and \(B\) are 2 matrices, \(A \otimes B\) represents the Kronecker product of \(A\) and \(B\), i.e. the block matrix whose block \((i, j)\) is \(A_{i,j} \otimes B\). If \(A\) is a square matrix, \(\text{Im}(A)\) and \(\text{Re}(A)\) represent the Hermitian matrices

\[
\text{Im}(A) = \frac{A - A^H}{2i}, \quad \text{Re}(A) = \frac{A + A^H}{2}
\]
If \((A_N)_{N \geq 1}\) (resp. \((b_N)_{N \geq 1}\)) is a sequence of matrices (resp. vectors) whose dimensions increase with \(N\), \((A_N)_{N \geq 1}\) (resp. \((b_N)_{N \geq 1}\)) is said to be uniformly bounded if \(\sup_{N \geq 1} \|A_N\| < +\infty\) (resp. \(\sup_{N \geq 1} \|b_N\| < +\infty\)).

If \(\nu \in [0, 1]\) and if \(R\) is an integer, we denote by \(d_R(\nu) = (1, e^{2i\pi\nu}, \ldots, e^{2i\pi(R-1)\nu})^T\), and by \(a_L(\nu) = \frac{1}{\sqrt{R}} d_R(\nu)\).

If \(x\) is a complex-valued random variable, the variance of \(x\), denoted by \(\text{Var}(x)\), is defined by
\[
\text{Var}(x) = E(|x|^2) - |E(x)|^2
\]
The zero-mean random variable \(x - E(x)\) is denoted \(x^\circ\).

Nice constants and nice polynomials

**Definition 1.2.** A nice constant is a positive constant independent of the dimensions \(L, M, N\) and complex variable \(z\). A nice polynomial is a polynomial whose degree is independent from \(L, M, N\), and whose coefficients are nice constants.

In the following, \(P_1\) and \(P_2\) will represent generic nice polynomials whose values may change from one line to another, and \(C(z)\) is a generic term of the form \(C(z) = P_1(|z|)P_2(1/\delta z)\).

**Background on Stieltjes transforms of positive matrix valued measures.** In the following, we denote by \(S_K(\mathbb{R}^+)\) the set of all Stieltjes transforms of \(K \times K\) positive matrix-valued measures \(\mu\) carried by \(\mathbb{R}^+\) verifying \(\mu_K(\mathbb{R}^+) = I_K\). The elements of the class \(S_K(\mathbb{R}^+)\) satisfy the following properties:

**Proposition 1.3.** Consider an element \(S(z) = \int_{\mathbb{R}^+} \frac{d\mu(\lambda)}{\lambda - z}\) of \(S_K(\mathbb{R}^+)\). Then, the following properties hold true:

- (i) \(S\) is analytic on \(\mathbb{C} \setminus \mathbb{R}^+\)
- (ii) \(\text{Im}(S(z)) \geq 0\) and \(\text{Im}(z S(z)) \geq 0\) if \(z \in \mathbb{C}^+\)
- (iii) \(\lim_{y \to +\infty} -iyS(iy) = I_K\)
- (iv) \(S(z)S^H(z) \leq \frac{I_K}{\delta^2}\) for each \(z \in \mathbb{C} \setminus \mathbb{R}^+\)
- (v) \(\int_{\mathbb{R}^+} \lambda d\mu(\lambda) = \lim_{y \to +\infty} \text{Re}(-iy(I_K + iyS(iy)))\)

Conversely, if a function \(S(z)\) satisfy properties (i), (ii), (iii), then \(S(z) \in S_K(\mathbb{R}^+)\).

While you have not been able to find a paper in which this result is proved, it has been well known for a long time (see however [9] for more details on (i), (ii), (iii), (v)), as well as Theorem 3 of [1] from which (iv) follows immediately).

2. Toeplitzification operators.

In the following derivations, it will be useful to consider the following Toeplitzification operators, which inherently depend on the correlation function \(r_m(\cdot)\). Let
\( \mathbf{J}_K \) denote the \( K \times K \) shift matrix with ones in the first upper diagonal and zeros elsewhere, namely \( \{\mathbf{J}_K\}_{i,j} = \delta_{j-i-1} \), and let \( \mathbf{J}^{-1}_K \) denote its transpose. For a given squared matrix \( \mathbf{M} \) with dimensions \( R \times R \), we define \( \Psi_{K}^{(m)}(\mathbf{M}) \) as an \( K \times K \) Toeplitz matrix with \((i,j)\)th entry equal to
\[
\left\{ \Psi_{K}^{(m)}(\mathbf{M}) \right\}_{i,j} = \sum_{l=-R+1}^{R-1} r_m(i-j-l) \tau(M)(l) \quad (2.1)
\]
or, alternatively, as the matrix
\[
\Psi_{K}^{(m)}(\mathbf{M}) = \sum_{n=-K+1}^{K-1} \left( \sum_{l=-R+1}^{R-1} r_m(n-l) \tau(M)(l) \right) \mathbf{J}_K^{-n} \quad (2.2)
\]
where the sequence \( \tau(M)(l), -R < l < R, \) is defined as
\[
\tau(M)(l) = \frac{1}{R} \text{tr} \left[ \mathbf{M} \mathbf{J}_R^l \right]. \quad (2.3)
\]
We can express this operator more compactly using frequency notation, namely
\[
\Psi_{K}^{(m)}(\mathbf{M}) = \sum_{n=-K+1}^{K-1} \left( \int_0^1 \mathcal{S}_m(\nu) a_R^H(\nu) \mathbf{M} a_K(\nu) e^{2\pi i mn} d\nu \right) \mathbf{J}_K^{-n} \\
= \int_0^1 \mathcal{S}_m(\nu) a_R^H(\nu) \mathbf{M} a_K(\nu) d_K(\nu) d_K^H(\nu) d\nu
\]
where \( a_R (\nu) = d_R(\nu) / \sqrt{R} \) and \( d_R(\nu) = (1, e^{2\pi i \nu}, \ldots, e^{2\pi i (R-1)\nu})^T \). In particular, when \( r_m(k) = \sigma^2 \delta_k \) (white observations), we have
\[
\Psi_{K}^{(m)}(\mathbf{M}) = \sigma^2 \sum_{n=-K+1}^{K-1} \frac{1}{R} \text{tr} \left[ \mathbf{M} \mathbf{J}_R^n \right] \mathbf{J}_K^{-n} = \sigma^2 \sum_{n=-K+1}^{K-1} \tau(M) \mathbf{J}_K^{-n}
\]
where \( \mathcal{T}_{K,R}(\mathbf{X}) \) is the classical Toeplitziation operator in [12]. The following properties are easily checked.

- Given a square matrix \( \mathbf{A} \) of dimension \( K \times K \) and a square matrix \( \mathbf{B} \) of dimension \( R \times R \), we can write
\[
\frac{1}{K} \text{tr} \left[ \mathbf{A} \Psi_{K}^{(m)} (\mathbf{B}) \right] = \int_0^1 \mathcal{S}_m(\nu) a_R^H(\nu) \mathbf{A} a_K(\nu) a_R^H(\nu) \mathbf{B} a_R(\nu) d\nu = \frac{1}{R} \text{tr} \left[ \Psi_{R}^{(m)}(\mathbf{A}) \mathbf{B} \right] \quad (2.4)
\]
- Given the square matrices \( \mathbf{B}, \mathbf{C} \) (of dimension \( K \times K \)) and \( \mathbf{D}, \mathbf{E} \) (of dimension \( R \times R \)), we have
\[
\frac{1}{K} \text{tr} \left[ \mathbf{B} \Psi_{K}^{(m)} (\mathbf{D} \Psi_{R}^{(m)} (\mathbf{C}) \mathbf{E}) \right] = \frac{1}{K} \text{tr} \left[ \mathbf{C} \Psi_{K}^{(m)} (\mathbf{D} \Psi_{R}^{(m)} (\mathbf{B}) \mathbf{E}) \right].
\]
• Given a square matrix $M$ and a positive integer $K$, we have
\[
\| \Psi_K^{(m)}(M) \| \leq \sup_{\nu \in [0,1]} |S_m(\nu) a_H^R(\nu) M a_L(\nu)| \leq \sup_{\nu \in [0,1]} |S_m(\nu)| \|M\|.
\]

• Given a square positive definite matrix $M$ and a positive integer $K$, condition (1.9) implies that
\[
\Psi^{(m)}_K(M) > 0. \tag{2.5}
\]

We define here two other operators that will be used throughout the paper, which respectively operate on $N \times N$ and $ML \times ML$ matrices. In order to keep the notation as simple as possible, we will drop the dimensions in the notation of these operators.

• Consider an $N \times N$ matrix $M$. We define $\Psi(M)$ as an $ML \times ML$ block diagonal matrix with $m$th diagonal block given by $\Psi^{(m)}(M)$.

• Consider an $ML \times ML$ matrix $M$, and let $M^{m,m}$ denote its $m$th $L \times L$ diagonal block. We define $\Psi(M)$ as the $N \times N$ matrix given by
\[
\Psi(M) = \frac{1}{M} \sum_{m=1}^{M} \Psi^{(m)}_N(M^{m,m}). \tag{2.6}
\]

$\Psi(M)$ can also be expressed as
\[
\Psi(M) = \sum_{n=-(N-1)}^{N-1} \sum_{l=-(L-1)}^{L-1} \tau^{(M)}(M(R(n-l) \otimes I_L))(l) J_N^{-n} \tag{2.7}
\]
where $\tau^{(M)}(A)(l)$ is defined for any $ML \times ML$ matrix $A$ by
\[
\tau^{(M)}(A)(l) = \frac{1}{ML} \text{tr} \left( A(I_M \otimes J_L^l) \right) = \frac{1}{L} \text{tr} \left[ \left( \frac{1}{M} \sum_{m=1}^{M} A^{m,m} \right) J_L^l \right]
\]
and where $R(m)$ is defined in (1.10). Note also that $\Psi(M)$ can alternatively be written as
\[
\Psi(M) = \frac{1}{M} \sum_{m=1}^{M} \int_0^{1} S_m(\nu) a_H^R(\nu) M^{m,m} a_L(\nu) d_N(\nu) d_N(\nu) d\nu.
\]

Given these two new operators, and if $A$ and $B$ are $ML \times ML$ and $N \times N$ matrices, we see directly from (2.4) that
\[
\frac{1}{N} \text{tr} \left[ \Psi(A) B \right] = \frac{1}{ML} \text{tr} \left[ A \Psi(B) \right]. \tag{2.8}
\]

3. Variance evaluations

In this section, we provide some estimates on the variance of certain quantities that depend on the resolvent $Q(z) = \left( W W^H - z I_{ML} \right)^{-1}$ and co-resolvent $\tilde{Q}(z) = \left( W^H W - z I_N \right)^{-1}$. We express the result in the following lemma.
Lemma 3.1. Let \((A_N)_{N \geq 1}\) be a sequence of deterministic \(ML \times ML\) matrices and \((G_N)_{N \geq 1}\) a uniformly bounded sequence of deterministic \(N \times N\) matrices. Then

\[
\text{Var}\left( \frac{1}{ML} \text{tr} A_N Q(z) \right) \leq \frac{C(z)}{MN} \frac{1}{ML} \text{tr}(A_N A_N^H) \tag{3.1}
\]

\[
\text{Var}\left( \frac{1}{ML} \text{tr} A_N Q(z) W G W^H \right) \leq \frac{C(z)}{MN} \frac{1}{ML} \text{tr}(A_N A_N^H) \tag{3.2}
\]

where \(C(z) = P_1(|z|) P_2(1/\delta_z)\) for two nice polynomials \(P_1, P_2\) (see Definition 1.2).

We devote the rest of this section to proving of this result. In order to short the notations, matrices \(A_N\) and \(G_N\) will be denoted by \(A\) and \(G\). We will be using the Poincaré-Nash inequality ([6], [5]), which, in the present context, can be formulated as follows ([15], [10]).

Lemma 3.2. Let \(\xi = \xi(W, W^*)\) denote a \(C^1\) complex function such that both itself and its derivatives are polynomially bounded. Under the above assumptions, we can write

\[
\text{Var}\xi \leq \sum_{m,i_1,i_2,j_1,j_2} \left( \frac{\partial \xi}{\partial (W_{i_1,j_1}^m)} \right)^* E \left[ W_{i_1,j_1}^m (W_{i_2,j_2}^m)^* \right] \frac{\partial \xi}{\partial (W_{i_2,j_2}^m)}^* + \sum_{m,i_1,i_2,j_1,j_2} \frac{\partial \xi}{\partial (W_{i_1,j_1}^m)} E \left[ W_{i_1,j_1}^m (W_{i_2,j_2}^m)^* \right] \left( \frac{\partial \xi}{\partial W_{i_2,j_2}^m} \right)^*
\]

where \(W_{i,j}^m\) is the \((m-1)L + i, j)\text{th entry of } W\).

We just check that the first term, denoted \(\beta\), on the right hand side of the upper bound of \(\text{Var}\xi\) is in accordance with the results claimed in Lemma 3.1 for \(\xi = \frac{1}{ML} \text{Tr}(AQ(z))\) and \(\xi = \frac{1}{ML} \text{Tr}(AQ(z)WGWH^H)\). For this, we establish that it is possible to be back to the case where the spectral densities \((S_m(\nu))_{m=1,...,M}\) all coincide with 1 which is covered by the results of [12]. More precisely, given the Hankel structure of the matrices \(W_m\), we can state that

\[
E \left[ W_{i_1,j_1}^m (W_{i_2,j_2}^m)^* \right] = \frac{1}{N} r_m (i_1 - i_2 + j_1 - j_2). \tag{3.3}
\]

Using that \(r_m(i_1 - i_2 + j_1 - j_2) = \int_0^1 e^{2\pi i (i_1 - i_2 + j_1 - j_2) \nu} S_m(\nu) d\nu\), we obtain immediately that \(\beta\) can be written as \(\beta = \mathbb{E}(\alpha)\) where \(\alpha\) is defined by

\[
\alpha = \frac{1}{N} \int_0^1 \sum_{m=1}^M S_m(\nu) \sum_{i_2,j_2} \frac{\partial \xi}{\partial (W_{i_2,j_2}^m)} e^{-2\pi i (i_2 + j_2) \nu} d\nu
\]

Thus, ([15], [10]) implies that \(\beta \leq C \hat{\beta}\), where \(\hat{\beta} = \mathbb{E}(\hat{\alpha})\) where \(\hat{\alpha}\) is defined by

\[
\hat{\alpha} = \frac{1}{N} \int_0^1 \sum_{m=1}^M \sum_{i_2,j_2} \frac{\partial \xi}{\partial (W_{i_2,j_2}^m)} e^{-2\pi i (i_2 + j_2) \nu} d\nu
\]
and where $C$ is a nice constant. It is clear that $\bar{\alpha}$ coincides $\alpha$ when $S_m(\nu) = 1$ for each $m = 1, \ldots, M$ and each $\nu \in [0, 1]$. When $\xi = \frac{1}{ML} \text{Tr}(AQ(z))$, it is proved in [12] that

$$\bar{\alpha} \leq \frac{1}{MN} \frac{1}{ML} \text{Tr}(QAQWW^HQ^H A^H Q^H).$$

As it holds that $QWW^H = I + zQ$ and that $\|Q\| \leq \frac{1}{\delta}$, we obtain that

$$QWW^H Q^H \leq \frac{1}{\delta z} (1 + |z|).$$

Therefore,

$$\bar{\alpha} \leq \frac{1}{\delta z^2} \left(1 + \frac{|z|}{\delta z}\right) \frac{1}{MN} \frac{1}{ML} \text{tr}(QAQ^H).$$

and using again $\|Q\| \leq \delta^{-1}$,

$$\bar{\beta} = E(\bar{\alpha}) \leq \frac{1}{\delta z^2} \left(1 + \frac{|z|}{\delta z}\right) \frac{1}{MN} \frac{1}{ML} \text{tr}(AA^H).$$

The conclusion follows from the observation that

$$\frac{1}{\delta z^2} \left(1 + \frac{|z|}{\delta z}\right) \leq \left[\frac{1}{\delta z^2} + \frac{1}{\delta^2}\right] (|z| + 1).$$

As for the case $\xi = \frac{1}{ML} \text{Tr}(AQ(z)WGW^H)$, we refer to upper bound of the term equivalent to $\bar{\alpha}$ expressed in Eq. (3.12-3.13) in [12], and omit further details.

4. Expectation of resolvent and co-resolvent

In this section, we analyze the expectation of the resolvent $Q(z) = \left(WW^H - zI_{ML}\right)^{-1}$ and co-resolvent $\tilde{Q}(z) = \left(W^HW - zI_N\right)^{-1}$. As a previous step, we need to ensure the properties of certain useful matrix valued functions. This is summarized in the following lemma.

**Lemma 4.1.** For $z \in \mathbb{C} \setminus \mathbb{R}^+$, the matrix $I_N + cN \bar{\Psi}(EQ(z))$ is invertible, so that we can define

$$\tilde{R}(z) = \frac{1}{z} \left(I_N + cN \bar{\Psi}(EQ(z))\right)^{-1}. \quad (4.1)$$

On the other hand, the matrix $I_{ML} + \Psi\left(\tilde{R}^T(z)\right)$ is also invertible, and we define

$$R(z) = \frac{1}{z} \left(I_{ML} + \Psi\left(\tilde{R}^T(z)\right)\right)^{-1}. \quad (4.2)$$

Furthermore, $\tilde{R}(z)$ and $R(z)$ are elements of $S_N(\mathbb{R}^+)$ and $S_{ML}(\mathbb{R}^+)$ respectively. In particular, they are holomorphic on $\mathbb{C} \setminus \mathbb{R}^+$ and satisfy

$$R(z)R^H(z) \leq \frac{1}{\delta z^2}, \quad \tilde{R}(z)\tilde{R}^H(z) \leq \frac{1}{\delta^2}. \quad (4.3)$$
Moreover, there exist two nice constants (see Definition 1.2) \( \eta \) and \( \tilde{\eta} \) such that

\[
\mathbf{R}(z)\mathbf{R}^H(z) \geq \frac{\delta^2}{16(\eta^2 + |z|^2)^2} \mathbf{I}_{ML} \tag{4.4}
\]

\[
\tilde{\mathbf{R}}(z)\tilde{\mathbf{R}}^H(z) \geq \frac{\delta^2}{16(\tilde{\eta}^2 + |z|^2)^2} \mathbf{I}_N. \tag{4.5}
\]

**Proof.** If \( z \in \mathbb{R}^* \), the invertibility of \( \mathbf{I}_N + c_N \overline{\Psi}(\mathbb{E}Q(z)) \) is obvious. If \( z \in \mathbb{C}^* \), it follows from the fact that

\[
\text{Im} [\mathbf{I}_N + c_N \overline{\Psi}(\mathbb{E}Q(z))] = c_N \overline{\Psi}(\mathbb{E}\text{Im}Q(z))
\]

and \( \text{Im}Q(z) > 0 \). We now establish that \( \tilde{\mathbf{R}}(z) \) and \( \mathbf{R}(z) \) are elements of \( \mathcal{S}_N(\mathbb{R}^+) \) and \( \mathcal{S}_{ML}(\mathbb{R}^+) \). By Proposition 1.3, we only need to prove that \( \text{Im} \tilde{\mathbf{R}}(z) \geq 0, \text{Im}z \tilde{\mathbf{R}}(z) \geq 0 \) when \( \text{Im}z > 0, \lim_{y \to +\infty} -iy \tilde{\mathbf{R}}(iy) = \mathbf{I}_N \), and similar properties for matrix \( \mathbf{R}(z) \). Clearly,

\[
\text{Im} \tilde{\mathbf{R}}(z) = \tilde{\mathbf{R}}^H(z) \left[ \text{Im}z \mathbf{I}_N + c_N \overline{\Psi}(\text{Im}z \mathbb{E}Q(z)) \right] \tilde{\mathbf{R}}(z) > 0
\]

\[
\text{Im} \mathbf{R}(z) = \mathbf{R}^H(z) \left[ \text{Im}z \mathbf{I}_{ML} + \Psi \left( \text{Im}z \tilde{\mathbf{R}}(z) \right) \right] \mathbf{R}(z) > 0
\]

whereas, noting that \( \mathbb{E}Q(iy) \to 0 \) as \( y \to +\infty \), we see that

\[
-iy \tilde{\mathbf{R}}(iy) = \left( \mathbf{I}_N + c_N \overline{\Psi}(\mathbb{E}Q(iy)) \right)^{-1} \to \mathbf{I}_N
\]

as \( y \to +\infty \). In order to justify that \( \mathbf{I}_{ML} + \Psi \left( \tilde{\mathbf{R}}^T(z) \right) \) is invertible, we remark that \( \text{Im} \left( \mathbf{I}_{ML} + \Psi \left( \tilde{\mathbf{R}}^T(z) \right) \right) \) coincides with \( \Psi \left( \text{Im} \tilde{\mathbf{R}}^T(z) \right) \) which is positive definite because \( \text{Im} \tilde{\mathbf{R}}(z) > 0 \) (see (2.5)). Therefore, \( \text{Im} \left( \mathbf{I}_{ML} + \Psi \left( \tilde{\mathbf{R}}^T(z) \right) \right) > 0 \) and \( \mathbf{I}_{ML} + \Psi \left( \tilde{\mathbf{R}}^T(z) \right) \) is invertible. Finally, observing that

\[
\text{Im} \mathbf{R}(z) = \mathbf{R}^H(z) \left[ \text{Im}z \mathbf{I}_{ML} + \Psi \left( \text{Im}z \tilde{\mathbf{R}}^T(z) \right) \right] \mathbf{R}(z) > 0
\]

\[
\text{Im} \tilde{\mathbf{R}}(z) = |z|^2 \mathbf{R}^H(z) \left[ \Psi \left( \text{Im} \tilde{\mathbf{R}}^T(z) \right) \right] \mathbf{R}(z) > 0
\]

together with the fact that, since \( \tilde{\mathbf{R}}(iy) \to 0 \) as \( y \to +\infty \),

\[
-iy \mathbf{R}(iy) = \left( \mathbf{I}_{ML} + \Psi \left( \tilde{\mathbf{R}}^T(iy) \right) \right)^{-1} \to \mathbf{I}_{ML}
\]

We eventually establish (4.4), and omit the proof of (4.5). For this, we notice that \( \mathbf{R}(z) \) is a block-diagonal matrix, and that measure \( \nu \) defined by \( \mathbf{R}(z) = \int_{\mathbb{R}^+} \frac{d\nu(\lambda)}{\lambda - z} \) is block diagonal as well. In order to establish (4.4), it is thus sufficient to prove that for each unit-norm \( L \)-dimensional vector \( \mathbf{b} \), it holds that

\[
\mathbf{b}^H \mathbf{R}^{m,m}(z)(\mathbf{R}^{m,m}(z))^H \mathbf{b} \geq \frac{\delta^2}{16(\eta^2 + |z|^2)^2} \tag{4.6}
\]
for some nice constant $\eta$ (of course independent on $m$ and $b$). For this, we remark that
\[
 b^H R^{m,m}(z)(R^{m,m}(z))^H b \geq |b^H R^{m,m}(z)b|^2
\]
We denote $\xi_m$ the term $\xi_m(z) = b^H R^{m,m}(z)b$ which can be written as
\[
 \xi_m(z) = \int_{\mathbb{R}^+} \frac{d\mu_{\xi_m}(\lambda)}{\lambda - z}
\]
where probability measure $\mu_{\xi_m}$ is defined by $d\mu_{\xi_m}(\lambda) = b^H d\nu^{m,m}(\lambda)b$. We claim that
\[
 |\xi_m(z)| \geq \delta_z \int_{\mathbb{R}^+} \frac{d\mu_{\xi_m}(\lambda)}{|\lambda - z|^2}  \tag{4.7}
\]
To justify this, we first remark that $\delta_z = |\text{Im}(z)|$ if $\text{Re}(z) \geq 0$ and that $\delta_z = |z|$ if $\text{Re}(z) \leq 0$. Next, we notice that $|\xi_m(z)| \geq |\text{Im}(\xi_m(z))| = |\text{Im}(z)| \int_{\mathbb{R}^+} \frac{d\mu_{\xi_m}(\lambda)}{|\lambda - z|^2}$ whatever the sign of $\text{Re}(z)$. Therefore, if $\text{Re}(z) \geq 0$, it holds that
\[
 |\xi_m(z)| \geq \delta_z \int_{\mathbb{R}^+} \frac{d\mu_{\xi_m}(\lambda)}{|\lambda - z|^2}
\]
If $\text{Re}(z) \leq 0$, $\text{Re}(\xi_m(z)) = \int_{\mathbb{R}^+} \frac{\lambda - \text{Re}(z)}{|\lambda - z|^2} d\mu_{\xi_m}(\lambda)$ verifies $\text{Re}(\xi_m(z)) \geq -\text{Re}(z) \int_{\mathbb{R}^+} \frac{d\mu_{\xi_m}(\lambda)}{|\lambda - z|^2}$. Therefore, if $\text{Re}(z) \leq 0$,
\[
 |\xi_m(z)|^2 = (\text{Im}(\xi_m(z))^2 + (\text{Re}(\xi_m(z))^2 \geq |z|^2 \left( \int_{\mathbb{R}^+} \frac{d\mu_{\xi_m}(\lambda)}{|\lambda - z|^2} \right)^2 = \delta_z^2 \left( \int_{\mathbb{R}^+} \frac{d\mu_{\xi_m}(\lambda)}{|\lambda - z|^2} \right)^2
\]
Therefore, (4.7) holds. We now consider the family of probability measures
\[
 \{(b_N^H d\nu^{m,m}_N(\lambda)b_N)_{N \geq 1, m = 1, \ldots, M, \|b_N\| = 1}\}
\]
where we have mentioned the dependency of $b$ and $\nu$ w.r.t. $N$. Using item (v) of Proposition 1.3 and hypothesis 1.8, it is easily seen that
\[
 \int_{\mathbb{R}^+} \lambda b_N^H d\nu^{m,m}_N(\lambda)b_N = b_N^H \Psi_L^m(I_N)b_N < C
\]
for some nice constant $C$. Therefore, it holds that
\[
 \sup_{N \geq 1, m = 1, \ldots, M, \|b_N\| = 1} \int_{\mathbb{R}^+} \lambda b_N^H d\nu^{m,m}_N(\lambda)b_N < +\infty
\]
The family of probability measures is thus tight, and it exists a nice constant $\eta$ such that
\[
 \inf_{N \geq 1, m = 1, \ldots, M, \|b_N\| = 1} b_N^H \nu^{m,m}_N([0, \eta])b_N > 1/2 \tag{4.8}
\]
We now use the obvious inequality
\[
 \int_{\mathbb{R}^+} \frac{b^H d\nu^{m,m}(\lambda)b}{|\lambda - z|^2} \geq \int_0^{\eta} \frac{b^H d\nu^{m,m}(\lambda)b}{|\lambda - z|^2} \geq \frac{1}{4(|z|^2 + \eta^2)}
\]
If $\lambda \in [0, \eta]$, it is clear that $|\lambda - z|^2 \leq 2(|z|^2 + \eta^2)$, and that
\[
 \int_0^{\eta} \frac{b^H d\nu^{m,m}(\lambda)b}{|\lambda - z|^2} \geq \frac{1}{4(|z|^2 + \eta^2)}
(4.7) eventually leads to
\[ b^H R^{m,m}(z)(R^{m,m}(z))^H b \geq |b^H R^{m,m}(z)b|^2 \geq \frac{\delta^2}{16(|z|^2 + \eta^2)^2} \]
as expected.

In order to address the expectation of \( Q(z) \) and \( \tilde{Q}(z) \) we will apply the integration by parts formula for the expectations of Gaussian functions, which is presented next.

**Lemma 4.2.** Let \( \xi = \xi(W, W^*) \) denote a \( C^1 \) complex function such that both itself and its derivatives are polynomically bounded. Under the above assumptions, we can write
\[ E\left[ W_{i_1,j_1}^m \xi \right] = \sum_{i_2=1}^L \sum_{j_2=1}^N E\left[ W_{i_1,j_1}^m (W_{i_2,j_2}^m)^* \right] E\left[ \frac{\partial \xi}{\partial (W_{i_2,j_2}^m)^*} \right] \]
where \( W_{i,j}^m \) is the \(((m-1)L+i,j)\)th entry of \( W \).

**Proof.** See [15, 10]. □

Consider the resolvent identity
\[ z Q(z) = Q(z) W W^H - I_{ML}. \] (4.9)
Let \( w_k \) denote the \( k \)th column of matrix \( W \), \( 1 \leq k \leq N \). For an \( ML \times ML \) matrix \( A \), we recall that we denote as \( [A]_{m_1,m_2} \) its \((m_1,m_2)\)th block matrix (of size \( L \times L \)) and as \( [A]_{i_1,i_2} \) the \((i_1,i_2)\)th entry of its \((m_1,m_2)\)th block. Applying the integration by parts formula in Lemma 4.2 and the identity in (4.9), we are able to write
\[
E \left[ \langle Q(z) w_k w_j^H \rangle_{i_1,i_2}^{m_1,m_2} \right] = \sum_{m_3,i_3} E \left[ [Q(z)]_{i_1,i_3}^{m_1,m_3} W_{i_3,k}^m (W_{i_2,j}^m)^* \right] E \left[ \frac{\partial [Q(z)]_{i_1,i_3}^{m_1,m_3} (W_{i_2,j}^m)^*}{\partial (W_{i_3,k}^m)^*} \right] \\
= \sum_{r=1}^N \sum_{i_4=1}^L \sum_{m_3,i_3} E \left[ W_{i_3,k}^m (W_{i_4,r}^m)^* \right] E \left[ \frac{\partial [Q(z)]_{i_1,i_3}^{m_1,m_3} (W_{i_2,j}^m)^*}{\partial (W_{i_3,k}^m)^*} \right] \\
= -\sum_{r=1}^N \sum_{m_3,i_3=1}^M \sum_{i_4=1}^L \frac{r_{m_3} (k-r+i_3-i_4)}{N} E \left[ \langle Q(z) w_i w_j^H \rangle_{i_1,i_2}^{m_1,m_2} [Q(z)]_{i_4,i_3}^{m_3,m_3} \right] \\
+ \sum_{i_3=1}^L \frac{r_{m_3} (k-j+i_3-i_2)}{N} E \left[ \langle Q(z) \rangle_{i_1,i_3}^{m_1,m_2} \right].
\]
Now, using the change of variable $i = i_4 - i_3$ we can alternatively express
\[
\mathbb{E} \left[ ( Q(z) w_L w_j^H \right]_{i_1, i_2}^{m_1, m_2} 
\]
\[
= -L \sum_{r=1}^{N} \sum_{m_3=1}^{M} \sum_{i=-L}^{L} \frac{r_{m_3} (k - r - i)}{N} \mathbb{E} \left[ ( Q(z) w_r w_j^H \right]_{i_1, i_2}^{m_1, m_2} \tau (Q^{m_3, m_3}(z)) (i) \right] 
\]
\[
+ \sum_{i_3=1}^{L} \frac{r_{m_3} (k - j + i_3 - i_2)}{N} \mathbb{E} \left[ ( Q(z) \right]_{i_1, i_3}^{m_1, m_2} 
\]
where we recall that, for a given square matrix $X$ of size $R$, the sequence $\tau (X) (i)$ is defined in (2.3).

Using the definition of the operator $\Psi^{(m)}_N$ and its averaged counterpart in (2.4), we may reexpress the above equation as
\[
\mathbb{E} \left[ ( Q(z) w_k w_j^H \right]_{i_1, i_2}^{m_1, m_2} = -c_N \mathbb{E} \left[ ( \overline{\Psi} (Q(z)) W^T Q(z) ) e_{i_1} e_{i_2}^T W^* \right]_{k, j} + \sum_{i_3=1}^{L} \frac{r_{m_3} (k - j + i_3 - i_2)}{N} \mathbb{E} \left[ ( Q(z) \right]_{i_1, i_3}^{m_1, m_2} 
\]
where we recall that $c_N = \frac{ML}{N}$. From (4.10) and using the definition of $\Psi(\cdot)$, we may generally write, for any $N \times N$ deterministic matrix $A$
\[
\mathbb{E} \left[ ( Q(z) W A W^H \right] = -c_N \mathbb{E} \left[ ( Q(z) W \overline{\Psi} ^T (Q(z)) ) A W^H \right] + \mathbb{E} \left[ Q(z) \Psi (A^T) \right]. 
\]

Let us now consider the co-resolvent, namely $\tilde{Q}(z) = (W^H W - zI_N)^{-1}$, together with the co-resolvent identity
\[
z \tilde{Q}(z) = \tilde{Q}(z) W^H W - I_N.
\]
Observe that we can write $\tilde{Q}(z) W^H W = W^H Q(z) W$ and therefore
\[
\mathbb{E} \left[ ( \tilde{Q}(z) W^H W \right]_{j, k} = \mathbb{E} \left[ ( W^H Q(z) W \right]_{j, k} = \text{tr} \mathbb{E} \left[ ( Q(z) w_k w_j^H \right].
\]
Hence, using the expression for the expectation of the resolvent in (4.10), we can obtain
\[
\mathbb{E} \left[ ( \tilde{Q}(z) W^H W \right]_{j, k} = \text{tr} \mathbb{E} \left[ ( Q(z) w_k w_j^H \right] = -c_N \mathbb{E} \left[ ( \tilde{Q}(z) W^H W \overline{\Psi} ^T (Q(z)) ) \right]_{j, k}
\]
\[
+ \sum_{m_3=1}^{M} \sum_{i_1=1}^{L} \sum_{i_3=1}^{L} \frac{r_{m_3} (k - j + i_3 - i_1)}{N} \mathbb{E} \left[ ( Q(z) \right]_{i_1, i_3}^{m_1, m_1} 
\]
The second term can be further simplified by applying the change of variables $i_1 = i + i_3$, namely
\[
\mathbb{E} \left[ ( \tilde{Q}(z) W^H W \right] = -c_N \mathbb{E} \left[ ( \tilde{Q}(z) W^H W \overline{\Psi} ^T (Q(z)) \right] + c_N \overline{\Psi} ^T (\mathbb{E} Q(z)).
\]
Proposition 4.3. For each deterministic sequence of $ML \times ML$ matrices $(A_N)_{N \geq 1}$ satisfying $\sup_N \|A_N\| < a < +\infty$, it holds that
\[
\left| \frac{1}{ML} \text{tr} [A_N \Delta(z)] \right| \leq a C(z) \frac{L}{MN}
\] (4.14)
where $C(z) = P_1(|z|)P_2(1/\delta z)$ for some nice polynomials $P_1$ and $P_2$ (see Definition 1.2) that do not depend on sequence $(A_N)_{N \geq 1}$. Moreover, if $(b_{1,N})_{N \geq 1}$ and $(b_{2,N})_{N \geq 1}$ are 2 sequences of $L$ dimensional vectors such that $\sup_N \|b_{1,N}\| < b < +\infty$ for $i = 1, 2$, and if $((d_{m,N})_{m=1,\ldots,M})_{N \geq 1}$ are deterministic complex number verifying $\sup_{N,m} |d_{m,N}| < d < +\infty$, then, it holds that
\[
\left| b_{1,N}^H \left( \frac{1}{M} \sum_{m=1}^M d_{m,N} \Delta^{m,m}(z) \right) b_{2,N} \right| \leq d b^2 C(z) \frac{L^{3/2}}{MN}
\] (4.15)
where $C(z)$ is defined as above, where the nice polynomials $P_1$ and $P_2$ do not depend on $(b_{1,N})_{N \geq 1}$, $(b_{2,N})_{N \geq 1}$ and $((d_{m,N})_{m=1,\ldots,M})_{N \geq 1}$.
We first establish (4.14), and denote $A_{N_r}(b_{l,N})_{l=1,2}$ and $(d_{m,N})_{m=1,...,M}$ by $A$, $(b_l)_{l=1,2}$ and $(d_m)_{m=1,...,M}$ in order to simplify the notations. We denote by $\xi$ the term $\frac{1}{ML}\text{tr}[A\Delta(z)]$, and express $\xi$ as

$$\xi = \frac{1}{ML}\text{tr}\left(\Psi^T (Q^\circ R)\tilde{R}W^H\tilde{Q}W\right).$$

Using (2.4), we obtain immediately that

$$\xi = \sum_{n=-(N-1)}^{N-1} \sum_{l=-(L-1)}^{L-1} \tau^{(M)} (Q^\circ (R(n-l) \otimes I_L)) (l) \tau \left(\tilde{R}W^H\tilde{Q}W\right) (n).$$

Therefore, $E(\xi)$ is equal to

$$E(\xi) = \sum_{n=-(N-1)}^{N-1} \sum_{l=-(L-1)}^{L-1} E \left[ \tau^{(M)} (Q^\circ (R(n-l) \otimes I_L)) (l) \tau \left(\tilde{R}W^H\tilde{Q}W\right)^\circ (n) \right].$$

Using the definition of operators $\tau$ and $\tau^{(M)}$, the Schwartz inequality, Lemma 3.1 and the inequality $J_L^n J_{L_L}^{(H)} \leq I_L$, we obtain that

$$\left| E \left[ \tau^{(M)} (Q^\circ (R(n-l) \otimes I_L)) (l) \tau \left(\tilde{R}W^H\tilde{Q}W\right)^\circ (n) \right] \right| \leq C(z) \frac{1}{MN} \left( \frac{1}{ML} \text{Tr}(R(n-l)R^H(n-l) \otimes I_L) \right)^{1/2}.$$

Therefore, it holds that

$$|E(\xi)| \leq \frac{C(z)}{MN} \sum_{n=-(N-1)}^{N-1} \sum_{l=-(L-1)}^{L-1} \left( \frac{1}{M} \sum_{m=1}^{M} |r_m(n-l)|^2 \right)^{1/2}$$

and that

$$|E(\xi)| \leq C(z) \frac{L}{MN} \sum_{n \in \mathbb{Z}} \left( \frac{1}{M} \sum_{m=1}^{M} |r_m(n)|^2 \right)^{1/2}.$$

Condition (1.7) thus implies (4.14).

In order to establish (4.15), we denote by $\eta$ the left hand side of (4.15), which can be written as

$$\eta = \frac{1}{M}\text{tr}(\Delta(D \otimes b_2 b_1^H))$$

where $D$ represents the $M \times M$ diagonal matrix with diagonal entries $d_1, \ldots, d_M$.

Using the above calculations, we obtain that $E(\eta)$ can be expressed as

$$E(\eta) = L \sum_{n=-(N-1)}^{N-1} \sum_{l=-(L-1)}^{L-1} E \left[ \tau^{(M)} (Q^\circ (R(n-l) \otimes I_L)) (l) \tau \left(\tilde{R}W^H R (D \otimes b_2 b_1^H)QW\right)^\circ (n) \right].$$
We use again the Schwartz inequality to evaluate $E \left[ \tau^{(M)} (Q^n(R(n - l) \otimes I_L)) (l) \tau \left( \tilde{R}W^H R(D \otimes b_2 b_2^H)QW \right)^\circ (n) \right]$ together with (3.2) for $A = R(D \otimes b_2 b_2^H)$, and obtain that
\[ E \left\| \tau (\tilde{R}W^H R(D \otimes b_2 b_2^H)QW)^\circ (n) \right\|^2 \leq b^2 C(z) \frac{1}{MN} \text{tr}(DD^H \otimes b_2 b_2^H) \]

The term \( \frac{1}{ML} \text{tr}(DD^H \otimes b_2 b_2^H) \) can also be written as
\[ \frac{1}{ML} \text{tr}(DD^H \otimes b_2 b_2^H) = \frac{1}{L} \left( \frac{1}{M} \sum_{m=1}^{M} |d_m|^2 \right) \|b_2\|^2 \]
and is thus bounded by \( b^2 d^2 \). Therefore, the Schwartz inequality leads to
\[ \left| E \left[ \tau^{(M)} (Q^n(R(n - l) \otimes I_L)) (l) \tau \left( \tilde{R}W^H R(D \otimes b_2 b_2^H)QW \right)^\circ (n) \right] \right| \leq b^2 d C(z) \frac{1}{MN \sqrt{L}} \left( \frac{1}{M} \sum_{m=1}^{M} |r_m (n - l)|^2 \right)^{1/2} \]  
(4.16)

Using the same approach as above, we immediately obtain (4.15).

**Corollary 4.4.** It holds that
\[ \|\Psi(\Delta)\| \leq C(z) \frac{L^{3/2}}{MN} \]  
(4.17)

(4.17) follows immediately from
\[ \|\Psi(\Delta)\| \leq \sup_{\nu \in [0,1]} \frac{1}{M} \sum_{m=1}^{M} S_m(\nu) |a_L^H(\nu) \Delta^m a_L(\nu)| \]
and from the application of (4.15) to the case $b_1 = b_2 = a_L(\nu)$ and $d_m = S_m(\nu)$.

5. The deterministic equivalents.

As $E(Q(z)) - R(z)$ converges towards zero in some appropriate sense, (4.1) and (4.2) suggest that it is reasonable to expect that $E(Q(z))$ behaves as the first component $T(z)$ of the solution $(T(z), \tilde{T}(z))$ of the so-called canonical equation
\[ T(z) = -\frac{1}{z} \left( I_{ML} + \Psi \left( \tilde{T}(z) \right) \right)^{-1} \]  
(5.1)
\[ \tilde{T}(z) = -\frac{1}{z} \left( I_N + cN \Psi^T (T(z)) \right)^{-1} \]  
(5.2)

In the following, we establish that the canonical equation has a unique solution. More precisely:
Proposition 5.1. There exists a unique pair of functions $(\mathbf{T}(z), \bar{\mathbf{T}}(z)) \in \mathcal{S}_{ML}(\mathbb{R}^+) \times \mathcal{S}_N(\mathbb{R}^+)$ that satisfy (5.1), (5.2) for each $z \in \mathbb{C} \setminus \mathbb{R}^+$. Moreover, there exist two nice constants (see Definition 1.2) $\eta$ and $\bar{\eta}$ such that
\[
\mathbf{T}(z) \Gamma H(z) \geq \frac{\delta^2_z}{16(\eta^2 + |z|^2)^2} \mathbf{I}
\]
\[
\bar{\mathbf{T}}(z) \bar{\Gamma} H(z) \geq \frac{\delta^2_z}{16(\bar{\eta}^2 + |z|^2)^2} \mathbf{I}
\]

We devote the rest of this section to proving this proposition. We will first prove existence of a solution by using a standard convergence argument.

Proposition 5.2. Let $\mathbf{\Gamma}^m(z), m = 1, \ldots, M$, be a collection of $L \times L$ matrix-valued complex function belonging to $\mathcal{S}_L(\mathbb{R}^+)$ and define $\mathbf{\Gamma}(z) = \text{diag}(\mathbf{\Gamma}^1(z), \ldots, \mathbf{\Gamma}^M(z))$. Likewise, let $\bar{\mathbf{\Gamma}}(z)$ be an $N \times N$ matrix-valued complex function belonging to $\mathcal{S}_N(\mathbb{R}^+)$. Consider the two matrices
\[
\mathbf{Y}(z) = -\frac{1}{z} \left( \mathbf{I}_{ML} + \Psi \left( \bar{\mathbf{\Gamma}}^T(z) \right) \right)^{-1}
\]
\[
\bar{\mathbf{Y}}(z) = -\frac{1}{z} \left( \mathbf{I}_N + c_N \bar{\mathbf{\Gamma}}^T(\mathbf{\Gamma}(z)) \right)^{-1}
\]
and let $\mathbf{Y}(z) = \text{diag}(\mathbf{Y}^1(z), \ldots, \mathbf{Y}^M(z))$. The matrix-valued functions $\mathbf{Y}^m(z), m = 1, \ldots, M$ and $\bar{\mathbf{Y}}(z)$ are analytic on $\mathbb{C} \setminus \mathbb{R}^+$ and belong to the classes $\mathcal{S}_L(\mathbb{R}^+)$ and $\mathcal{S}_N(\mathbb{R}^+)$ respectively.

Proof. The proof follows the lines of [19] Proposition 5.1. We first need to prove that $\mathbf{Y}^m(z)$ and $\bar{\mathbf{Y}}(z)$ are analytic on $\mathbb{C} \setminus \mathbb{R}^+$. To see this, observe that if $\mathbf{A}(z)$ is an analytic matrix-valued function, so is $\Psi^m_K(\mathbf{A}(z)), m = 1, \ldots, M$. Therefore, we only need to show $\det \left( z \mathbf{I}_L + \Psi_L^m \left( z \bar{\mathbf{\Gamma}}^T(z) \right) \right) \neq 0$ and $\det \left( z \mathbf{I}_N + c_N \bar{\mathbf{\Gamma}}^T(z) \right) \neq 0$ when $z \in \mathbb{C} \setminus \mathbb{R}^+$. Let $\mathbf{h}$ denote an arbitrary $L \times 1$ column vector such that $\left( z \mathbf{I}_L + \Psi_L^m \left( z \bar{\mathbf{\Gamma}}^T(z) \right) \right) \mathbf{h} = 0$. If $z \in \mathbb{C}^+$, have
\[
0 = \left| \mathbf{h}^H \left( z \mathbf{I}_L + \Psi_L^m \left( z \bar{\mathbf{\Gamma}}^T(z) \right) \right) \mathbf{h} \right| \geq 1 \mathbb{M} \mathbf{h}^H \left( z \mathbf{I}_L + \Psi_L^m \left( z \bar{\mathbf{\Gamma}}^T(z) \right) \right) \mathbf{h}
\]
\[= \mathbf{h}^H \left( \mathbf{I}_L \mathbf{I}_L + \Psi_L^m \left( \mathbf{I}_L \bar{\mathbf{\Gamma}}^T(z) \right) \right) \mathbf{h} \geq 1 \mathbb{M} \mathbf{h}^2 \geq 0
\]
where we have used $\mathbb{M} \mathbf{z} \bar{\mathbf{\Gamma}}^T(z) \geq 0$ because $\bar{\mathbf{\Gamma}}(z) \in \mathcal{S}_N(\mathbb{R}^+)$. From the above chain of inequalities we see that we can only have $\mathbf{h} = \mathbf{0}$. The same argument is valid when $z \in \mathbb{C}^-$. On the other hand, when $z \in \mathbb{R}^-$, we will have $-z \bar{\mathbf{\Gamma}}^T(z) \geq 0$ and
\[
0 = \mathbf{h}^H \left( -z \mathbf{I}_L + \Psi_L^m \left( -z \bar{\mathbf{\Gamma}}^T(z) \right) \right) \mathbf{h} \geq |z| \mathbf{h}^2 \geq 0
\]
which also implies that $\mathbf{h} = \mathbf{0}$. A similar argument proves that $\det \left( z \mathbf{I}_N + c_N \bar{\mathbf{\Gamma}}^T(z) \right) \neq 0$ when $z \in \mathbb{C} \setminus \mathbb{R}^+$. 
Next, we prove that $\text{Im}[\Upsilon^m(z)] \geq 0$ and $\text{Im}[\tilde{\Upsilon}^m(z)] \geq 0$ when $z \in \mathbb{C}^+$. Observe that, using the identity $A^{-1} - B^{-1} = A^{-1}(B - A)B^{-1}$, we have
\[
\text{Im}[\Upsilon^m(z)] = (\Upsilon^m(z))^H \left[ \text{Im}[\Psi_L^m(\tilde{T}(z))] \right] \Upsilon^m(z) \geq 0
\]
because $\text{Im}[z\tilde{T}(z)] \geq 0$ since $\tilde{T}(z) \in \mathcal{S}_N(\mathbb{R}^+)$. On the other hand, we also have
\[
\text{Im}[z\Upsilon^m(z)] = [z\Upsilon^m(z)]^H \left[ \Psi_L^m(\tilde{T}(z)) \right] [z\Upsilon^m(z)] \geq 0
\]
because $\text{Im}[\tilde{T}(z)] \geq 0$ since $\tilde{T}(z) \in \mathcal{S}_N(\mathbb{R}^+)$. Consequently, Proposition 1.3 implies that $\Upsilon^m(z), \tilde{T}(z)$ are analytic on $\mathbb{C}^+$. Observe that we have a recurrent relationship through the identity $T(z) = \tilde{T}(z)$ for each $z \in \mathbb{C}^+$. Our first objective is to show that, for $z \in \mathbb{C}^+$, we have $A^{-1} - B^{-1} = (B - A)B^{-1}$, namely
\[
\epsilon^{(p+1)}(z) = \Theta_p(\epsilon^{(p)}(z))
\]
and note that we have a recurrent relationship through the identity $A^{-1} - B^{-1} = (B - A)B^{-1}$, namely
\[
\tilde{\epsilon}^{(p+1)}(z) = \tilde{\Theta}_p(\tilde{\epsilon}^{(p)}(z))
\]
where we have defined the operators
\[
\Theta_p(X) = c_N z^2 T^{(p+1)}(z) \Psi \left( \overline{T}^{(p)}(z) \overline{X}(X) \overline{T}^{(p-1)}(z) \right) T^{(p)}(z)
\]
\[
\widehat{\Theta}_p(X) = c_N z^2 \overline{T}^{(p)}(z) \overline{T}^{(p)}(z) \overline{(X^T)} \overline{T}^{(p)}(z) \overline{T}^{(p+1)}(z)
\]
for \( p \geq 1 \). Using the properties of the operators we can obviously establish that
\[
\max \left\{ \| \Theta_p(X) \|, \| \widehat{\Theta}_p(X) \| \right\} \leq \sup_{N} c_N \sup_{m,M,\nu} |S_m(\nu)|^2 \frac{|z|^2}{(\text{Im}z)^4} \|X\|.
\]
Consider the domain
\[
\mathcal{D} = \left\{ z \in \mathbb{C}^+: \sup_{N} c_N \sup_{m,M,\nu} |S_m(\nu)|^2 \frac{|z|^2}{(\text{Im}z)^4} < \frac{1}{2} \right\}.
\]
For \( z \in \mathbb{C}^+ \) we clearly see that both \( \Theta_p(X) \) and \( \widehat{\Theta}_p(X) \) are contractive and therefore the sequences \( (T^{(p)}(z))_p \) and \( (\overline{T}^{(p)}(z))_p \) are both Cauchy and have limits, which will be denoted by \( T(z) \) and \( \overline{T}(z) \). Since the sequences \( (T^{(p)}(z))_p \) and \( (\overline{T}^{(p)}(z))_p \) are uniformly bounded on compact subsets of \( \mathbb{C} \setminus \mathbb{R}^+ \) (because they belong to \( \mathcal{S}_{ML}(\mathbb{R}^+) \) and \( \mathcal{S}_N(\mathbb{R}^+) \) respectively), Montel’s theorem establishes that \( T(z) \) and \( \overline{T}(z) \) are analytic on \( \mathbb{C} \setminus \mathbb{R}^+ \).

It remains to prove that \( T(z) \) and \( \overline{T}(z) \) respectively belong to \( \mathcal{S}_{ML}(\mathbb{R}^+) \) and \( \mathcal{S}_{N}(\mathbb{R}^+) \) and that they satisfy the canonical system of equations. From the fact that \( \text{Im}T^{(p)}(z) \geq 0, \text{Im}zT^{(p)}(z) \geq 0 \) and \( T^{(p)}(z)T^{(p)}(z)^H \leq \delta_z^{-1}I \) for \( p \geq 1 \) we have \( \text{Im}T(z) \geq 0, \text{Im}zT(z) \geq 0 \) and \( T(z)T(z)^H \leq \delta_z^{-1}I \). The same argument applies to \( \overline{T}(z) \). On the other hand, using the reasoning in the proof of Lemma 4.1 we clearly see that both \( (I_{ML} + \Psi (\overline{T}^T(z))) \) and \( (I_N + c_N \overline{X}(X^T) \overline{T}(z))) \) are invertible for \( z \in \mathbb{C} \setminus \mathbb{R}^+ \), and that they are the limits of the corresponding terms on right hand side of (5.5)-(5.6). This shows that the pair \( T(z), \overline{T}(z) \) satisfies the canonical system of equations. Noting that
\[
\lim_{y \to \infty} -iyT(iy) = \lim_{y \to \infty} (I_{ML} + \Psi (\overline{T}^T(iy)))^{-1} = I_{ML}
\]
(because \( \|\overline{T}(z)\| < \delta_z^{-1}I \)) we can conclude \( T(z) \) belongs to \( \mathcal{S}_{ML}(\mathbb{R}^+) \). A similar reasoning shows that \( \overline{T}(z) \) belongs to \( \mathcal{S}_N(\mathbb{R}^+) \).

Following the proof of (4.1)-(4.2), it is easy to check that each solution of (5.4)

(5.2) satisfies (5.3) (5.4).

Let us now prove unicity. For this, it would be possible to use arguments based on the analyticity of the solutions and the Montel theorem as in the existence proof. We however prefer to use a different approach because the corresponding ideas will
be used later, and rather prove that for each \( z \), system (5.1, 5.2) considered as a system in the set of \( ML \times ML \) and \( N \times N \) matrices, has a unique solution. We fix \( z \in \mathbb{C} \setminus \mathbb{R}^+ \), and assume that \( T(z), \tilde{T}(z) \) and \( S(z), \tilde{S}(z) \) are matrices that are solutions of the system (5.1, 5.2) of equations at point \( z \). It is easily seen that

\[
T(z) - S(z) = c_N z^2 S(z) \Psi \left( \tilde{S}^T(z) \Psi \left( T(z) - S(z) \right) \tilde{T}^T(z) \right) T(z) \quad (5.7)
\]

The above equation can alternatively be written as

\[
T(z) - S(z) = \Phi_0 (T(z) - S(z))
\]

where we have defined the operator \( \Phi_0(X) \) as

\[
\Phi_0(X) = c_N z^2 S(z) \Psi \left( \tilde{S}^T(z) \Psi \left( T(z) - S(z) \right) \tilde{T}^T(z) \right) T(z) \quad (5.8)
\]

where \( X \) is an \( ML \times ML \) block-diagonal matrix. We note that operator \( \Phi_0 \) depends on point \( z \), but we do not mention this dependency in order to simplify the notations. Our objective is to show that the equation \( \Phi_0(X) = X \) accepts a unique solution in the set of block-diagonal matrices, which is trivially given by \( X = 0 \). This will imply that \( T(z) = S(z) \), contradicting the original hypothesis.

We iteratively define \( \Phi_0^{(n)}(X) = \Phi_0(\Phi_0^{(n-1)}(X)) \) for \( n \in \mathbb{N} \), with \( \Phi_0^{(1)}(X) = \Phi_0(X) \). Let \( \Phi_0^{(n)}(X)^{m,m} \) denote the \( L \times L \) sized \( m \)th diagonal block of \( \Phi_0^{(n)}(X) \). In the following, we establish that for block diagonal \( ML \times ML \) matrix \( X \), it holds that \( \lim_{n \to +\infty} \Phi_0^{(n)}(X)^{m,m} = 0 \). If this property holds, a solution of the equation \( X = \Phi_0(X) \) satisfies \( X = \Phi_0^{(n)}(X) \) for each \( n \), thus leading to \( X = 0 \). It is useful to mention that in the following analysis, dimensions \( L, M, N \) are fixed. We establish the following Proposition, which, of course, implies that each element of matrix \( \Phi_0^{(n)}(X) \) converges towards 0, i.e. that matrix \( \Phi_0^{(n)}(X) \) converges towards 0.

**Proposition 5.3.** For each \( m = 1, \ldots, M \), and for each \( L \)-dimensional vectors \( a \) and \( b \), it holds that

\[
\left| a^H \Phi_0^{(n)}(X)^{m,m} b \right| \to 0
\]

as \( n \to \infty \) for each \( ML \times ML \) matrix \( X \).

To simplify the notation, we drop the dependence on \( z \) from \( T(z), \tilde{T}(z), S(z) \) and \( \tilde{S}(z) \) in what follows. We begin by defining two operators \( \Phi_S(X) \) and \( \Phi_{T^H}(X) \) that operate on \( ML \times ML \) matrices as

\[
\Phi_S(X) = c_N \left| z \right|^2 S \Psi \left( \tilde{S}^T \Psi \left( X \right) \tilde{S}^* \right) S^H
\]

\[
\Phi_{T^H}(X) = c_N \left| z \right|^2 T^H \Psi \left( \tilde{T}^T \Psi \left( X \right) \tilde{T}^* \right) T.
\]

We remark that \( \Phi_S(X) \geq 0 \) and \( \Phi_{T^H}(X) \geq 0 \) if \( X \geq 0 \). Matrices \( T, \tilde{T}, S, \tilde{S} \) being solutions of equations (5.1, 5.2) are non singular. Therefore, \( \Phi_S(X) \) and \( \Phi_{T^H}(X) \) are also positive definite as soon as \( X \) is positive definite.
Consider the integral representation of the $m$th diagonal block of $\Phi_0(X)$, that is
\[
\Phi_0(X)^{m,m} = c_N z^2 \int_0^1 \int_0^1 F_m(\nu, \alpha) S^{m,m} d_L(\nu) a_N^H(\nu) \tilde{S} d_N(\alpha) \times
\]
\[
\times d_N^H(\alpha) \tilde{T} a_N(\nu) d_L^H(\nu) T^{m,m} \, d\nu d\alpha
\]
where
\[
F_m(\nu, \alpha) = S_m(\nu) \frac{1}{M} \sum_{k=1}^M S_k(\alpha) a_H^m(\alpha) X^{k,k} a_L(\alpha).
\]
It turns out that, for each integer $n \geq 0$ and each $m = 1, \ldots, M$ we have
\[
\Phi_0^{(n+1)}(X)^{m,m} \left(\Phi_{T^H}^{(n+1)}(I)^{m,m}\right)^{-1} \left(\Phi_0^{(n+1)}(X)^{m,m}\right)^H \leq
\]
\[
\leq \Phi_S \left(\Phi_0^{(n)}(X) \left(\Phi_{T^H}^{(n)}(I)^{-1} \Phi_0^{(n)}(X)^H\right)^{m,m}\right)
\]
(5.11)

To see this, consider the matrix
\[
\mathcal{M}_m(X, B) = \begin{bmatrix}
\Phi_S \left(\Phi_0 \left(\Phi_{T^H}^{-1} X^H\right)^{m,m}ight) \\
\Phi_0^{H}(X)^{m,m} \\
\Phi_{T^H}(B)^{m,m}
\end{bmatrix}
\]
(5.12)
where $B$ is an arbitrary $ML \times ML$ Hermitian positive definite block-diagonal matrix. It turns out that $\mathcal{M}_m(X, B) \geq 0$. Indeed, to see this we only need to observe that this matrix can alternatively be expressed as
\[
\mathcal{M}_m(X, B) = \frac{c_N}{M} \sum_{k=1}^M \int_0^1 \int_0^1 S_m(\nu) S_k(\alpha) \Psi_{m,k}(X, B) \Psi_{m,k}(X, B)^H \, d\nu d\alpha
\]
where
\[
\Psi_{m,k}(X, B) = \begin{bmatrix}
z S^{m,m} d_L(\nu) a_H^m(\nu) \tilde{S} d_N(\alpha) a_H^m(\alpha) X^{k,k} (B^{k,k})^{-1/2} \\
(z^* (B^{m,m})^H d_L(\nu) a_H^m(\nu) \tilde{T} d_N(\alpha) a_H^m(\alpha) (B^{k,k})^{1/2}
\end{bmatrix}
\]

Now, since $\mathcal{M}_m(X, B) \geq 0$, the Schur complement of this matrix will also be positive semidefinite, so that we can state
\[
\Phi_0(X)^{m,m} \left(\Phi_{T^H}(B)^{m,m}\right)^{-1} \Phi_0^{H}(X)^{m,m} \leq \Phi_S \left(\Phi_0 \left(\Phi_{T^H}^{-1} X^H\right)^{m,m}\right).
\]
Thus, fixing $B = \Phi_{T^H}^{(n)}(I)$ and replacing $X$ with $\Phi_0^{(n)}(X)$ in the above equation, we directly obtain (5.11).

By iterating the inequality in (5.11) and using the positivity of the operator $\Phi_S(\cdot)$ we obtain
\[
\Phi_0^{(n)}(X)^{m,m} \left(\Phi_{T^H}^{(n)}(I)^{m,m}\right)^{-1} \left(\Phi_0^{(n)}(X)^{m,m}\right)^H \leq \Phi_S^{(n)} \left(XX^H\right)^{m,m}
\]
and
\[
\Phi_0^{(n)}(X) \left(\Phi_{T^H}^{(n)}(I)\right)^{-1} \left(\Phi_0^{(n)}(X)\right)^H \leq \Phi_S^{(n)} \left(XX^H\right).
\]
(5.13)
We can now finalize the proof of Proposition 5.3 by noting that, by the Cauchy-Schwarz inequality and the above inequality
\[
\left| a^H \Phi_0^{(n)}(X)^{m,m} b \right| \\
\leq \left[ a^H \Phi_0^{(n)}(X)^{m,m} \left( \Phi_0^{(n)}(I)^{m,m} \right)^{-1} \left( \Phi_0^{(n)}(X)^{m,m} \right)^H a \right]^{1/2} \left( b^H \left( \Phi_0^{(n)}(I)^{m,m} \right) b \right)^{1/2} \\
\leq \left[ a^H \Phi_S^{(n)} \left( XX^H \right)^{m,m} a \right]^{1/2} \left[ b^H \Phi_0^{(n)}(I)^{m,m} b \right]^{1/2}.
\]

Therefore, to conclude the proof we only need to show that both \( \Phi_0^{(n)} \left( XX^H \right)^{m,m} \) and \( \Phi_0^{(n)}(I)^{m,m} \) converge to zero as \( n \to \infty \). This can be shown following the steps in [12], as established in the following proposition.

**Lemma 5.4.** Let \( T(z), \tilde{T}(z) \) be a solution to the canonical equation \( 5.1, 5.2 \) at point \( z \), and let \( \Phi_T^{(n)}(B) \) be defined, for a positive semidefinite \( B \), as in \( 5.7 \). Then, it holds that
\[
\Phi_T^{(n)}(B) \to 0 \tag{5.14}
\]
and
\[
\Phi_T^{(n)}(B) \to 0 \tag{5.15}
\]
as \( n \to \infty \). Moreover, the series \( \sum_{n=0}^{+\infty} \Phi_T^{(n)}(B) \) and \( \sum_{n=0}^{+\infty} \Phi_T^{(n)}(B) \) are finite.

**Proof.** If \( T \) is a solution to the canonical equation, we must have
\[
\text{Im} T = \frac{T - T^H}{2i} = \text{Im} z T T^H + \Phi_T(\text{Im} T) \tag{5.16}
\]
or equivalently
\[
\frac{\text{Im} T}{\text{Im} z} = TT^H + \Phi_T \left( \frac{\text{Im} T}{\text{Im} z} \right) \tag{5.17}
\]
if \( \text{Im}(z) \neq 0 \). If \( z \) belongs to \( \mathbb{R}^+ \), then \( \frac{\text{Im} T}{\text{Im} z} \) should be interpreted as positive matrix \( T'(z) = \int_{\mathbb{R}^+} \frac{d\mu(\lambda)}{(\lambda - z)^2} \), and the reader may verify that the following arguments are still valid. Iterating the above relationship, we see that for any \( n \in \mathbb{N} \)
\[
\frac{\text{Im} T}{\text{Im} z} = \sum_{k=0}^{n} \Phi_T^{(k)}(TT^H) + \Phi_T^{(n+1)} \left( \frac{\text{Im} T}{\text{Im} z} \right).
\]
Since \( \frac{\text{Im} T}{\text{Im} z} \geq 0 \), we have \( \Phi_T^{(n+1)} \left( \frac{\text{Im} T}{\text{Im} z} \right) \geq 0 \). On the other hand, we also have \( \Phi_T^{(k)}(TT^H) \geq 0 \) and therefore it holds that for each \( n \),
\[
\sum_{k=0}^{n} \Phi_T^{(k)}(TT^H) \leq \frac{\text{Im} T}{\text{Im} z}
\]
The series \( \sum_{k=0}^{+\infty} \Phi_T^{(k)} (TT^H) \) is thus convergent and we must have \( \Phi_T^{(n)} (TT^H) \rightarrow 0 \) as \( n \rightarrow \infty \). Since matrix \( T \) is invertible, \( T^H T > \alpha(z) I \) where \( \alpha(z) > 0 \). Therefore, \( \alpha(z) \Phi_T^{(n)} (I) \leq T^H T \), which implies that \( \Phi_T^{(n)} (I) \) converges towards 0 and that \( \sum_{n=0}^{+\infty} \Phi_T^{(n)} (I) < +\infty \). Now, consider a general positive semidefinite \( B \). Then, \( B \leq \|B\| I \) and \( \Phi_T^{(n)} (B) \leq \|B\| \Phi_T^{(n)} (I) \). Hence, it holds that \( \Phi_T^{(n)} (B) \rightarrow 0 \) and \( \sum_{n=0}^{+\infty} \Phi_T^{(n)} (B) < +\infty \). In particular, \( \Phi_T^{(n+1)} (I) \rightarrow 0 \) as \( n \rightarrow \infty \) and

\[
\frac{\Im T}{\Im z} = \sum_{k=0}^{+\infty} \Phi_T^{(k)} (TT^H).
\]

In order to establish \( \sum_{n=0}^{+\infty} \Phi_T^{(n)} (I) < +\infty \), we use the observation that \( \frac{\Im T}{\Im z} = T^H T + \Phi_T^H \left( \frac{\Im T}{\Im z} \right) \) and use the same arguments as above.

\( \square \)

**Remark 5.5.** In the above analysis, \( L, M, N \) are fixed parameters. Therefore, \( \alpha(z) \) a priori depends on \( L, M, N \) as well as the norms of the series \( \sum_{n=0}^{+\infty} \Phi_T^{(n)} (I) \). In the following, a more precise analysis will be needed, and it will be important to show that such an \( \alpha(z) \) can be chosen independent from \( L, M, N \), and that the

\[
\sup_N \| \sum_{n=0}^{+\infty} \Phi_T^{(n)} (I) \| < +\infty.
\]

### 6. Convergence towards the deterministic equivalent.

If \( (A_N)_{N \geq 1} \) is a sequence of deterministic uniformly bounded \( ML \times ML \) matrices, Lemma 3.1 implies that the rate of convergence of \( \text{var} \left( \frac{1}{ML} \text{tr} [A_N Q(z)] \right) \) is \( O \left( \frac{1}{MN} \right) \). In the absence of extra assumptions on \( M \) (e.g. \( M = O(N^\epsilon) \) for \( \epsilon > 0 \)), this does not allow to conclude that

\[
\frac{1}{ML} \text{tr} (A_N [Q(z) - \mathbb{E}(Q(z))]) \rightarrow 0
\]

almost surely. In order to obtain the almost sure convergence, we use the identity

\[
\mathbb{E} \left[ \frac{1}{ML} \text{tr} (A_N Q^2(z))^4 \right] = \mathbb{E} \left[ \left( \frac{1}{ML} \text{tr} (A_N Q^2(z)) \right)^2 \right] + \text{var} \left[ \left( \frac{1}{ML} \text{tr} (A_N Q^2(z)) \right)^2 \right],
\]

remark that

\[
\mathbb{E} \left[ \left( \frac{1}{ML} \text{tr} (A_N Q^2(z)) \right)^2 \right] \leq \left[ \text{var} \left( \frac{1}{ML} \text{tr} [A_N Q(z)] \right) \right]^2 \leq C(z) \frac{1}{(MN)^2},
\]

\[
\left[ \text{var} \left( \frac{1}{ML} \text{tr} [A_N Q(z)] \right) \right]^2 \leq C(z) \frac{1}{(MN)^2},
\]

where \( C(z) \) is a constant depending on \( z \).
and establish using the Nash-Poincaré inequality that
\[
\text{var} \left( \frac{1}{ML} \text{tr} (A_N Q^T(z)) \right)^2 \leq C(z) \frac{1}{(MN)^2}
\]
(the proof is straightforward and thus omitted). Markov inequality and Borel-Cantelli’s Lemma immediately imply that (6.1) holds, and that
\[
\frac{1}{ML} \text{tr} (A_N [Q(z) - \mathbb{E}(Q(z))]) = O_P \left( \frac{1}{\sqrt{MN}} \right).
\]
In the following, we study the behaviour of \(\frac{1}{ML} \text{tr} [A_N (E Q(z) - T(z))]\). In this section, we first establish that for each sequence of deterministic uniformly bounded \(ML \times ML\) matrices \((A_N)_{N \geq 1}\), it holds that
\[
\frac{1}{ML} \text{tr} [A_N (E Q(z) - T(z))] \to 0 \quad (6.2)
\]
for each \(z \in \mathbb{C} \setminus \mathbb{R}^+\), a property which, by virtue of Proposition 4.3, is equivalent to
\[
\frac{1}{ML} \text{tr} [A_N (R(z) - T(z))] \to 0 \quad (6.3)
\]
for each \(z \in \mathbb{C} \setminus \mathbb{R}^+\). However, (6.2) does not provide any information on the rate of convergence. Under the extra-assumption that
\[
\frac{L^{3/2}}{MN} \to 0 \quad (6.4)
\]
we establish that
\[
\left| \frac{1}{ML} \text{tr} [A_N (E Q(z) - T(z))] \right| \leq C(z) \frac{L}{MN} \quad (6.5)
\]
or equivalently that
\[
\left| \frac{1}{ML} \text{tr} [A_N (R(z) - T(z))] \right| \leq C(z) \frac{L}{MN} \quad (6.6)
\]
when \(z\) belongs to a set \(E_N\) defined by
\[
E_N = \{ z \in \mathbb{C} \setminus \mathbb{R}^+, \frac{L^{3/2}}{MN} P_1(|z|) P_2(1/\delta_z) < 1 \}
\]
where \(P_1\) and \(P_2\) are some nice polynomials. When (6.4) holds, each element \(z \in \mathbb{C} \setminus \mathbb{R}^+\) belongs to \(E_N\) for \(N\) greater than a certain integer depending on \(z\). Therefore, (6.6) implies that the rate of convergence of \(\frac{1}{ML} \text{tr} [A_N (E Q(z) - T(z))]\) towards 0 is \(O(\frac{1}{MN})\) for each \(z \in \mathbb{C} \setminus \mathbb{R}^+\).
6.1. Proof of (6.3).

In order to simplify the notations, matrix $A_N$ is denoted by $A$. Writing $R(z) - T(z)$ as $R(z) (R^{-1}(z) - T^{-1}(z)) T(z)$ and $R(z) - T(z) = T(z) (T^{-1}(z) - R^{-1}(z)) R(z)$, we obtain immediately that

$$
R(z) - T(z) = z R(z) \Psi \left( \left( \tilde{R}(z) - \tilde{T}(z) \right)^T \right) T(z)
$$

(6.7)

$$
\left( \tilde{R}(z) - \tilde{T}(z) \right)^T = z c_N \tilde{R}^T(z) \overline{\Psi} (E Q(z) - T(z)) \tilde{T}^T(z).
$$

(6.8)

We introduce the linear operator $\Phi_1$ defined on the set of all $ML \times ML$ matrices by

$$
\Phi_1(X) = z^2 c_N R(z) \Psi \left( \tilde{R}^T(z) \overline{\Psi}(X) \tilde{T}^T(z) \right) T(z).
$$

(6.9)

The operator $\Phi_1$ is clearly obtained from operator $\Phi_0$ defined by replacing matrices $S(z)$ and $S(z)$ by matrices $R(z)$ and $R(z)$. Then, it holds that

$$
R(z) - T(z) = \Phi_1 (R(z) - T(z)) + \Phi_1 (\Delta(z)).
$$

(6.10)

Thus, matrix $R(z) - T(z)$ can be interpreted as the solution of the linear equation (6.10). Therefore, in some sense, showing that $R(z) - T(z)$ converges towards 0 can be proved by showing that operator $I - \Phi_1$ is invertible, and that the action of its inverse on $\Phi_1 (\Delta(T(z))$ still converges towards 0. In this subsection, we implicitly prove that $\Phi_1$ is a contractive operator for $z$ well chosen, obtain that

$$
\frac{1}{ML} \text{tr}[A (R(z) - T(z))] = O(\frac{1}{MN})
$$

for such $z$, and use Montel’s theorem to conclude that (6.3) holds for each $z \in \mathbb{C} \setminus \mathbb{R}^+$.

Using (2.8), we remark that for each $ML \times ML$ matrices $A$ and $B$,

$$
\frac{1}{ML} \text{tr}(\Phi_1 (B) A)) = \frac{1}{ML} \text{tr}(B \Phi_1^t (A))
$$

(6.11)

where $\Phi_1^t$ represents the linear operator defined on the $ML \times ML$ matrices by

$$
\Phi_1^t(A) = z^2 c_N \Psi \left( \tilde{T}^T \overline{\Psi}[TAR] \tilde{R}^T \right).
$$

(6.12)

We remark that operator $\Phi_1^t$ is related to the adjoint $\Phi_1^*$ of $\Phi_1$ w.r.t. the scalar product $\langle A, B \rangle = \frac{1}{ML} \text{tr}(AB^*)$ through the relation $\Phi_1^t (A) = (\Phi_1^* (A^H))^H$.

If $A$ is a $ML \times ML$ deterministic matrix, (6.10) leads to

$$
\frac{1}{ML} \text{tr}[A (R(z) - T(z))] = \frac{1}{ML} \text{tr} [\Phi_1^t(A) (R(z) - T(z)) + \frac{1}{ML} \text{tr} [\Phi_1^t(A) \Delta(z)]
$$

(6.13)

Obviously, from the properties of the operators $\Psi(\cdot)$ and $\overline{\Psi}(\cdot)$ we can write

$$
\| \Phi_1^t(A) \| \leq |z|^2 c_N \sup_{m,M,\nu} |S_m(\nu)|^2 \| R(z) \| \| T(z) \| \| A \| \| T(z) \|
$$

$$
\leq \frac{|z|^2}{(\delta z)^4} c_N \sup_{m,M,\nu} |S_m(\nu)|^2 \| A \|.
$$
Let us consider the domain
\[ D = \left\{ z \in \mathbb{C} \setminus \mathbb{R}^+ : \frac{|z|^2}{(\delta z)^4} \sup_{N} \sup_{m,M,\nu} |S_m(\nu)|^2 < \frac{1}{2} \right\}. \]
and define \( \alpha(z) \) as
\[ \alpha(z) = \sup_{\|B\| \leq 1} \left| \frac{1}{ML} \text{tr} \left( (R(z) - T(z))B \right) \right|. \]
Then, we establish that if \( z \in D \), then \( \alpha(z) \leq C(z) \frac{L}{MN} \). For this, we consider \( \mathbf{A} \) such that \( \|\mathbf{A}\| \leq 1 \). Using that
\[ \left| \frac{1}{ML} \text{tr} \left[ \Phi_1'(\mathbf{A}) (R(z) - T(z)) \right] \right| \leq \alpha(z) \|\Phi_1'(\mathbf{A})\| \]
and that \( \|\Phi_1'(\mathbf{A})\| \leq 1/2 \) if \( z \in D \), we deduce from (6.13) that
\[ \alpha(z) \leq \frac{\alpha(z)}{2} + \sup_{\|\mathbf{A}\| \leq 1} \left| \frac{1}{ML} \text{tr} \left( \Phi_1'(\mathbf{A}) \Delta(z) \right) \right|. \]
As \( \|\Phi_1'(\mathbf{A})\| \leq 1/2 \) if \( \|\mathbf{A}\| \leq 1 \), (6.14) implies that
\[ \sup_{\|\mathbf{A}\| \leq 1} \left| \frac{1}{ML} \text{tr} \left( \Phi_1'(\mathbf{A}) \Delta(z) \right) \right| \leq C(z) \frac{L}{MN}. \]
This implies that \( \alpha(z) \leq C(z) \frac{L}{MN} \) for each \( z \in D \), and that for each uniformly bounded sequence of \( ML \times ML \) matrices \( \mathbf{A}_N \), (6.3) holds on \( D \). Montel's theorem immediately implies that (6.3) also holds for each \( z \in \mathbb{C} \setminus \mathbb{R}^+ \).

6.2. Proof of (6.5).
We now establish (6.5) for each \( z \in \mathbb{C} \setminus \mathbb{R}^+ \) under Assumption (6.4). For this, we establish that the linear equation (6.10) can be solved for each \( z \in \mathbb{C} \setminus \mathbb{R}^+ \). For this, we first prove the following proposition.

**Proposition 6.1.** It exists 2 nice polynomials \( P_1 \) and \( P_2 \) (see Definition 1.2) such that for each \( ML \times ML \) matrix \( \mathbf{X} \), the series \( \sum_{n=0}^{\infty} \Phi_1^{(n)}(\mathbf{X}) \) is convergent when \( z \) belongs the set \( E_N \) defined by
\[ E_N = \{ z \in \mathbb{C} \setminus \mathbb{R}^+ : \frac{L^3/2}{MN} P_1(\|z\|) P_2(1/\delta z) < 1 \}. \]
In order to establish Proposition 6.1, we first remark that for each matrix \( \mathbf{X} \), it holds that
\[ \Phi_1^{(n)}(\mathbf{X}) \left( \Phi_1^{(n)}(\mathbf{I}) \right)^{-1} \left( \Phi_1^{(n)}(\mathbf{X}) \right)^H \leq \Phi_1^{(n)}(\mathbf{X} \mathbf{X}^H) \]
where \( \Phi_{\mathbf{T}_N}(-) \) is defined in (5.10) and where \( \Phi_{\mathbf{R}_N}(-) \) is as in (5.9) replacing \( \mathbf{S} \) with \( \mathbf{R} \). This inequality is proved in the same way as (5.13). It has already been proved that \( \sum_{n=0}^{\infty} \Phi_1^{(n)}(\mathbf{I}) \) is convergent. Following the proof of the uniqueness in
Spectral Convergence of Large Block-Hankel Gaussian Random Matrices

Proposition 5.1, we will obtain the convergence of the series \( \sum_{n=0}^{\infty} \Phi^{(n)}_1(X) \), i.e. that

\[
\sum_{n=0}^{\infty} \left| a^H \Phi^{(n)}_1(X)b \right| < +\infty
\]

if we are able to establish that

\[
\sum_{n=0}^{\infty} \Phi^{(n)}_R(XX^H) < +\infty. \tag{6.16}
\]

When \( \text{Im} z \neq 0 \), we can write

\[
\frac{\text{Im}(R)}{\text{Im}(z)} = RR^H + \Phi_R \left( \frac{\text{Im}(E(Q))}{\text{Im}(z)} \right)
\]

Therefore, it holds that

\[
\frac{\text{Im}(E(Q))}{\text{Im}(z)} = RR^H + \frac{\text{Im}(\Delta)}{\text{Im}(z)} + \Phi_R \left( \frac{\text{Im}(E(Q))}{\text{Im}(z)} \right). \tag{6.17}
\]

When \( z \in \mathbb{R}^- \), we can still interpret \( \frac{\text{Im}(R)}{\text{Im}(z)} \) and \( \frac{\text{Im}(E(Q))}{\text{Im}(z)} \) as \( R'(z) \) and \( E(Q'(z)) \) and the following reasoning holds as well. In order to use the ideas of the proof of the uniqueness in Proposition 5.1, matrix \( RR^H + \frac{\text{Im}(\Delta)}{\text{Im}(z)} \) should be positive. By (4.4), matrix \( RR^H \) verifies \( RR^H \geq \delta^2 z Q_2(|z|^2)I \) for some nice polynomial \( Q_2 \). In order to guarantee the positivity of \( RR^H + \frac{\text{Im}(\Delta)}{\text{Im}(z)} \) on a large subset of \( \mathbb{C} \setminus \mathbb{R}^+ \), condition \( \| \frac{\text{Im}(\Delta)}{\text{Im}(z)} \| \to 0 \) should hold. However, it can be shown that the rate of convergence of \( \| \frac{\text{Im}(\Delta)}{\text{Im}(z)} \| \) is \( O((L/M^3)^{1/2}) \). Assuming that \( L/M^3 \to 0 \) is a stronger condition than Assumption (6.4) which is equivalent to \( L/M^4 \to 0 \). Therefore, we have to modify the proof of the uniqueness in Proposition 5.1. Instead of considering Eq. (6.17), we consider

\[
\Phi_R \left( \frac{\text{Im}(E(Q))}{\text{Im}(z)} \right) = RR^H + \frac{\text{Im}(\Delta)}{\text{Im}(z)} + \Phi_R \left( \frac{\text{Im}(E(Q))}{\text{Im}(z)} \right) \tag{6.18}
\]

This time, we will see that \( \Phi_R \left( RR^H + \frac{\text{Im}(\Delta)}{\text{Im}(z)} \right) \geq \delta^2 z Q_2(|z|^2)I \) when \( z \) belongs to a set \( E_N \) defined by (6.14), and this property allows to prove (6.16) if \( z \in E_N \). In order to establish this, we first state the following Lemma.

**Lemma 6.2.** It holds that

\[
\| \Psi \left( \frac{\text{Im}(\Delta)}{\text{Im}(z)} \right) \| \leq C(z) \frac{L^{3/2}}{M N} \tag{6.19}
\]

**Proof.** Following the proof of Corollary 4.4, it is sufficient to establish that if \( (b_{1,n})_{N \geq 1} \) and \( (b_{2,n})_{N \geq 1} \) are two sequences of \( L \) dimensional vectors such that
\[ \sup_N \| b_{i,N} \| < b < +\infty \text{ for } i = 1, 2, \text{ and if } (|d_{m,N}|_{m=1}^{M})_{N \geq 1} \text{ are deterministic complex number verifying } \sup_{N,m} |d_{m,N}| < d < +\infty, \text{ then, it holds that} \]
\[ \left| b_{1,N}^* \left( \frac{1}{M} \sum_{m=1}^{M} d_{m,N} \frac{\im \omega_{m,m}}{\im(z)} \right) b_{2,N} \right| \leq d b^2 P_1(|z|) P_2(1/d) \frac{L^{3/2}}{MN} \tag{6.20} \]

for some nice polynomials \( P_1 \) and \( P_2 \). (6.20) can be established by adapting in a straightforward way the arguments of the proof of Lemma B-1 of [11]. This completes the proof of the Lemma. \( \square \)

Using the definition of operator \( \Phi R \) and the properties of \( R \) and \( \tilde{R} \), we deduce from Lemma 6.2 that
\[ \left\| \Phi_R \left( \frac{\im \Omega}{\im(z)} \right) \right\| \leq C(z) \frac{L^{3/2}}{MN} \]
when \( z \in \mathbb{E}_N \). As \( R(z)R^H(z) \geq \frac{\delta^2}{Q_2(|z|)} I_{ML} \), it holds that \( \Psi(R(z)R^H(z)) \geq \frac{\delta^2}{Q_2(|z|)} \Psi(I_{ML}) \). Since all spectral densities \( (S_m) \) verify (1.9), it is clear that \( \Psi(I_{ML}) \geq C I_N \) for some nice constant \( C \). Therefore, it appears that
\[ \Psi(R(z)R^H(z)) \geq C \frac{\delta^2}{Q_2(|z|)} I_N \]
Lemma 6.2 thus implies that
\[ \Psi \left( R(z)R(z)^H + \frac{\im \Omega}{\im(z)} \right) \geq C/2 \frac{\delta^2}{Q_2(|z|)} I_N \]
on the set \( E_N \) defined by
\[ E_N = \{ z \in \mathbb{C} \setminus \mathbb{R}^+, C(z) \frac{L^{3/2}}{MN} \leq C/2 \frac{\delta^2}{Q_2(|z|)} \} \]
which can be written as in (6.14). Since matrix \( \tilde{R}^T(z)\tilde{R}^*(z) \) is also greater than \( \frac{\delta^2}{Q_2(|z|)} \) for some nice polynomial \( Q_2 \) (see (4.5)), we eventually obtain that
\[ \Phi_R \left( R(z)R(z)^H + \frac{\im \Omega}{\im(z)} \right) \geq \frac{\delta^6}{Q_2(|z|)} I_{ML} \tag{6.21} \]
for each \( z \in \mathbb{E}_N \). Using the same arguments than in the proof of the uniqueness in Proposition 5.1, we obtain that \( \Phi_{R}^{(n)} \left( R(z)R^H(z) + \frac{\im \Omega}{\im(z)} \right) \to 0 \) when \( n \to 0 \), and that
\[ \Phi_R \left( \frac{\im(E(Q))}{\im(z)} \right) = \sum_{n=0}^{\infty} \Phi_{R}^{(n)} \left( \Phi_R \left( R(z)R^H(z) + \frac{\im \Omega}{\im(z)} \right) \right) \]
when \( z \in \mathbb{E}_N \). Using (6.21) as well as
\[ \Phi_R \left( \frac{\im(E(Q))}{\im(z)} \right) \leq C(z) I \]
we eventually obtain that
$$\sum_{n=0}^{+\infty} \Phi_R^{(n)}(I) \leq C(z) I$$
when \( z \in E_N \). Therefore, for each \( ML \times ML \) matrix \( X \), it holds that
$$\sum_{n=0}^{+\infty} \Phi_R^{(n)}(XX^*) \leq \|X\|^2 \sum_{n=0}^{+\infty} \Phi_R^{(n)}(I) \leq C(z) \|X\|^2 I < +\infty$$
In order to complete the proof of Proposition 6.1, we just follow the proof of unicity of Proposition 5.1. We express \( a^H \Phi_1(X)b \) as
$$a^H \Phi_1^{(n)}(X)b = a^H \Phi_1^{(n)}(X) \left[ \Phi_T^{(n)}(I) \right]^{-1/2} \left[ \Phi_T^{(n)}(I) \right]^{1/2} b$$
use the Schwartz inequality as well as (6.15), and obtain that
$$|a^H \Phi_1^{(n)}(X)b| \leq \left( \sum_{n=0}^{+\infty} a^H \Phi_R^{(n)}(XX^*)a \right)^{1/2} \left( \sum_{n=0}^{+\infty} b^H \Phi_T^{(n)}(I)b \right)^{1/2}$$
and that
$$\sum_{n=0}^{+\infty} |a^H \Phi_1^{(n)}(X)b| \leq \left( \sum_{n=0}^{+\infty} a^H \Phi_R^{(n)}(XX^*)a \right)^{1/2} \left( \sum_{n=0}^{+\infty} b^H \Phi_T^{(n)}(I)b \right)^{1/2} < +\infty$$
as expected.

We are now in position to complete the proof of (6.6). For this, we consider a uniformly bounded sequence of \( ML \times ML \) matrices \( A_N \) and evaluate \( \frac{1}{ML} \text{tr}(A_N(R(z) - T(z))) \). As previously, matrix \( A_N \) is denoted by \( A \) in order to short the notations. For this, we take Eq. (6.10) as a starting point, and assume that \( z \) belongs to the set \( E_N \) defined by (6.14). As \( z \in E_N \), the series
$$\sum_{n=0}^{+\infty} \Phi_1^{(n)}(\Phi_1(\Delta))$$
is convergent and
$$R - T = \sum_{n=0}^{+\infty} \Phi_1^{(n)}(\Phi_1(\Delta))$$
(6.22)
Therefore,
$$\frac{1}{ML} \text{tr}(A(R - T)) = \sum_{n=0}^{+\infty} \frac{1}{ML} \text{tr} \left( A \Phi_1^{(n+1)}(\Delta) \right)$$
or equivalently,
$$\frac{1}{ML} \text{tr}(A(R - T)) = \sum_{n=0}^{+\infty} \frac{1}{ML} \text{tr} \left( \Delta \Phi_1^{(n+1)}(\Delta) \right)$$
where $\Phi_t^1$ is the operator defined by (6.12). The strategy of the proof consists in showing that the series $\sum_{n=0}^{\infty} \Phi_t^{(n+1)}(A)$ is convergent, and that
\[
\sup_N \left\| \sum_{n=0}^{\infty} \Phi_t^{(n+1)}(A) \right\| < +\infty. \tag{6.23}
\]
If (6.23) holds, (4.14) will imply that
\[
\left| \sum_{n=0}^{\infty} \Phi_t^{(n+1)}(A) \right| \leq C(z) \frac{L}{MN}
\]
if $z \in E_N$.

In order to establish the convergence of the series as well as (6.23), we use the following inequality: for each $ML \times ML$ deterministic matrix $A$, it holds that
\[
\Phi_t^{(n)}(A) \left[ \Phi_t^{(n)}(I) \right]^{-1} \left( \Phi_t^{(n)}(A) \right)^H \leq \Phi_{R^H}^{(n)}(A^H A) \tag{6.24}
\]
where the operators $\Phi_t^T$ and $\Phi_{R^H}^T$ are defined by
\[
\Phi_t^T(X) = c_N |z|^2 \Psi \left( T^T \Psi(TXT^H) \right) \Psi \left( T^T \Psi(TXT^H) \right), \Phi_{R^H}^T(X) = c_N |z|^2 \Psi \left( R^T \Psi(R^H XR) \right) \Psi \left( R^T \Psi(R^H XR) \right) \tag{6.25}
\]
The proof is similar to the proof of (6.15), and is thus omitted. We remark that operators $\Phi_t^T$ and $\Phi_{R^H}^T$ are linked by the formula:
\[
\Phi_t^{(n)}(X) = T^{-1} \Phi_t^{(n)}(T XT^H) T^{-H} \tag{6.26}
\]
which implies that
\[
\Phi_t^{(n)}(X) = T^{-1} \Phi_t^{(n)}(T XT^H) T^{-H} \tag{6.27}
\]
Since $\sum_{n=0}^{\infty} \Phi_t^{(n)}(I) < +\infty$, it holds that
\[
\sum_{n=0}^{\infty} \Phi_t^{(n)}(I) \leq \|T^{-1}\|^2 \|T\|^2 \sum_{n=0}^{\infty} \Phi_t^{(n)}(I) < +\infty
\]
Moreover, we have already shown that $\sum_{n=0}^{\infty} \Phi_t^{(n)}(I) \leq C(z) I$, and that $TT^H \geq \frac{\delta_2^2}{\|z\|^2} I$, or equivalently that $\|T^{-1}\|^2 \leq C(z)$. Therefore, it holds that
\[
\sum_{n=0}^{\infty} \Phi_t^{(n)}(I) \leq C(z) I. \tag{6.28}
\]
In order to control the series $\sum_{n=0}^{\infty} \Phi_{R^H}^{(n)}(A^H A)$, we remark that
\[
\Phi_{R^H}^{(n)}(X) = R^{-H} \Phi_{R^H}^{(n)}(R^H XR) R^{-1} \tag{6.29}
\]
which implies that
\[
\Phi_{R^H}^{(n)}(X) = R^{-H} \Phi_{R^H}^{(n)}(R^H XR) R^{-1} \tag{6.30}
\]
Using the same kind of arguments as above, we obtain that
\[ \sum_{n=0}^{+\infty} \Phi_R^{t(n)}(A^*A) \leq C(z) I \]  
(6.31)
if \( z \) belongs to a set \( E_N \) defined by (6.14). Noting that
\[ a^H \sum_{n=0}^{+\infty} \Phi_1^{t(n)}(A)b \leq \left[ a^H \left( \sum_{n=0}^{+\infty} \Phi_T^{t(n)}(I) \right) a \right]^{1/2} \left[ b^H \left( \sum_{n=0}^{+\infty} \Phi_R^{t(n)}(A^*A) \right) b \right]^{1/2} \]
we obtain that
\[ \| \sum_{n=0}^{\infty} \Phi_1^{t(n)}(A) \| \leq C(z) \]
as soon as \( z \in E_N \). This completes the proof of (6.6).
