Cross-diffusions and Turing instabilities

Abstract

We show that the ill-posedness observed for cross-diffusion systems, that is due to backward parabolicity, can be interpreted as a limiting Turing instability of a corresponding semi-linear parabolic system. Our analysis is based on the, now well established, derivation of cross-diffusions from reaction-diffusion systems for fast reaction rates.

We illustrate our observation with two generic examples for 2×2 and 4×4 reaction-diffusion systems. For these examples, we prove that backward parabolicity in cross-diffusion systems is equivalent to Turing instability for fast reaction rates. In one dimension, the Turing patterns are periodic solutions which frequency increases with the reaction rate. Furthermore, in some specific cases, the structure of the equations at hand involves classical entropy/Lyapunov functions which lead to a priori estimates allowing to rigorously pass to the fast reaction limit in the absence of Turing instabilities.

1 Introduction and model equations

The derivation of cross-diffusion dynamic from fast reactions in parabolic systems, after it was observed in [10, 13], has known a growing interest during the past few decade [5, 4, 7, 1, 20] and the subject is well established.

Here, we consider specific form of cross-diffusion systems as in

$$\partial_t w_i - \Delta[A_i(w)] = 0, \quad i = 1, \dots, I,$$

where the nonlinearity A depends on the solution vector $w = (w_1, \dots, w_I)$ and satisfies $A_i(w)|_{w_i=0} = 0$. We aim at proving the equivalence between instability by backward parabolicity for these cross-diffusion equations and Turing instabilities for fast reaction-diffusion systems. Let us point out that this type of instability is very different from that mentioned already in [10, 13] which is the continuation of Turing instability through their asymptotic process when some reaction terms remain in the cross-diffusion system, as it is the case in the famous SKT model [25, 6].

Our motivation comes from the fast dynamics of attachment and detachment of synaptic receptors to scaffold proteins which has been observed and modeled in [24, 9], leading to large dynamical aggregates [22]. This attachment and detachment dynamics has been analyzed, with a different scaling than that we propose here, in [11].

For our purpose, we first consider the simple case of two coupled equations with mass conservation leading formally to a nonlinear diffusion equation when the reaction rate goes to infinity. Then, we extend our analysis to the setting of four coupled reaction-diffusion equations with mass conservation, leading formally, when the reaction rate goes to infinity, to two coupled cross-diffusion equations.

We now describe more precisely the two settings of our study, the main general properties of the involved equations and the limit equation obtained heuristically when the fast of the reaction term goes to $+\infty$.

1.1 Case of 2 coupled reaction-diffusion equations

We begin with a very simple example. We consider a smooth bounded domain $\Omega \subset \mathbb{R}^d$ and nonnegative solutions of the singular perturbation problem with Neumann boundary conditions

$$\begin{cases} \partial_t u_\varepsilon - d_1 \Delta u_\varepsilon = \varepsilon^{-1}(v_\varepsilon - F(u_\varepsilon)), & x \in \Omega, t \geq 0 \\ \partial_t v_\varepsilon - d_2 \Delta v_\varepsilon = -\varepsilon^{-1}(v_\varepsilon - F(u_\varepsilon)), \\ \frac{\partial u_\varepsilon}{\partial \nu} = \frac{\partial v_\varepsilon}{\partial \nu} = 0, & \text{on } \partial\Omega, \end{cases} \quad (1)$$

where the diffusion coefficients satisfy $d_1 > 0$, $d_2 > 0$ and

$$F \in \mathcal{C}^2(\mathbb{R}_+; \mathbb{R}_+) \text{ satisfies } F' > -1, \quad F(0) = 0, \quad F(u) > 0 \text{ for } u > 0. \quad (2)$$

With these assumptions, solutions remain non-negative, and it is also convenient to impose an upper bound $u \leq u_M$, $v \leq v_M = F(u_M)$ for some u_M such that

$$v_M \geq F(u) \quad \forall u, 0 \leq u \leq u_M.$$

In particular the set of equilibria is parametrized by the equation $v = F(u)$. The small parameter $\varepsilon > 0$ measures the time scale of reaction compared to diffusion.

This particular setting is also used to model mechanisms of cell polarisation [12], [19], and have generated many mathematical contributions [23, 17, 15, 16]. Indeed, the authors, see [17] and references therein, exhibit specific entropy functionals that we recall below and allow for a full asymptotic theory.

As specified, summing the two equations, we obtain the first basic property of this system, that is the conservation law,

$$\partial_t w_\varepsilon - \Delta[d_1 u_\varepsilon + d_2 v_\varepsilon] = 0, \quad w_\varepsilon = u_\varepsilon + v_\varepsilon, \quad (3)$$

which implies that

$$\int_{\Omega} (u_{\varepsilon}(x, t) + v_{\varepsilon}(x, t)) dx =: M \quad \text{is independent of } t. \quad (4)$$

Heuristically, when $\varepsilon \rightarrow 0$, we expect that $(u_{\varepsilon}, v_{\varepsilon}) \rightarrow (u, v)$, and $v = F(u)$. Therefore, from (3), we get

$$\partial_t w - \Delta(d_1 u + d_2 F(u)) = 0, \quad w = u + F(u).$$

The condition (2) implies that one can invert the mapping $u \mapsto w = u + F(u)$, and thus write

$$d_1 u + d_2 F(u) = A(w), \quad A \in \mathcal{C}^1(\mathbb{R}^+ \times \mathbb{R}^+),$$

which formally generates the equation

$$\begin{cases} \partial_t w - \Delta A(w) = 0, & x \in \Omega, t \geq 0, \\ \frac{\partial w}{\partial \nu} = 0, & \text{on } \partial\Omega. \end{cases} \quad (5)$$

Notice that we have

$$A'(w) = \frac{d_1 + d_2 F'(u)}{1 + F'(u)}, \quad w = u + F(u).$$

Using the assumption (2), when $d_2/d_1 \leq 1$, this equation is parabolic, of porous medium type, and there is an entropy/Lyapunov functional, i.e., a functional of $u_{\varepsilon}, v_{\varepsilon}$ which is decreasing with time if $F' \geq -\frac{d_2}{d_1}$ (see Proposition 2.8).

Our goal is to give conditions on F , around a given constant steady state $(\bar{u}, \bar{v})$, that means $\bar{v} = F(\bar{u})$, for which the following holds. For d_2/d_1 large enough and ε small enough, the state $(\bar{u}, \bar{v})$ is Turing unstable for (1), and this turns out to be equivalent to the backward parabolicity of the limiting equation, which means $A'(\bar{w}) < 0$.

We recall that the forward-backward parabolic Equation (5) is ill-posed under the condition $A'(\bar{w}) < 0$, however this problem has attracted a lot of interest and a theory of Young-measure solutions could certainly be derived along the lines of [18, 2, 21, 8, 26, 14].

1.2 Case of 4 coupled reaction-diffusion equations

Next, we extend the method to the case of four coupled equations, leading, in the fast reaction rate limit, to a 2×2 cross-diffusion equations. We explore again the correspondance between Turing instability and backward parabolicity in the cross-diffusion system equation.

We consider the following system, built with symmetry between two sets of variables,

$$\begin{cases} \partial_t u_{\varepsilon}^1 - d_1 \Delta u_{\varepsilon}^1 = \frac{1}{\varepsilon} \left[R(v_{\varepsilon}, w_{\varepsilon}) + \frac{u_{\varepsilon}^2}{2} - \frac{u_{\varepsilon}^1}{2} \right], \\ \partial_t u_{\varepsilon}^2 - d_2 \Delta u_{\varepsilon}^2 = -\frac{1}{\varepsilon} \left[R(v_{\varepsilon}, w_{\varepsilon}) + \frac{u_{\varepsilon}^2}{2} - \frac{u_{\varepsilon}^1}{2} \right], \\ \partial_t u_{\varepsilon}^3 - d_3 \Delta u_{\varepsilon}^3 = \frac{1}{\varepsilon} \left[S(v_{\varepsilon}, w_{\varepsilon}) + \frac{u_{\varepsilon}^4}{2} - \frac{u_{\varepsilon}^3}{2} \right], \\ \partial_t u_{\varepsilon}^4 - d_4 \Delta u_{\varepsilon}^4 = -\frac{1}{\varepsilon} \left[S(v_{\varepsilon}, w_{\varepsilon}) + \frac{u_{\varepsilon}^4}{2} - \frac{u_{\varepsilon}^3}{2} \right], \end{cases} \quad (6)$$

with

$$v_\varepsilon = \frac{u_\varepsilon^1 + u_\varepsilon^2}{2}, \quad w_\varepsilon = \frac{u_\varepsilon^3 + u_\varepsilon^4}{2}.$$

This system can be seen as the extension of the system (1) with the modification that the nonlinearity $F(u + v) - v$ replaces $F(u) - v$. The corresponding equilibrium, which cancel the right hand side, turns out to be defined by

$$\begin{cases} u^1 = v + R(v, w), & u^2 = v - R(v, w), \\ u^3 = w + S(v, w), & u^4 = w - S(v, w). \end{cases} \quad (7)$$

We immediately see that, formally, the corresponding cross-diffusion system is given by

$$\begin{cases} \partial_t v - \Delta A(v, w) = 0, \\ \partial_t w - \Delta B(v, w) = 0, \end{cases} \quad (8)$$

with

$$A(v, w) = \frac{d_1 + d_2}{2}v + \frac{d_1 - d_2}{2}R(v, w), \quad B(v, w) = \frac{d_3 + d_4}{2}w + \frac{d_3 - d_4}{2}S(v, w). \quad (9)$$

At this stage, it is useful to introduce some assumptions. In order to preserve positivity, we assume (consider first that u_ε^1 vanishes and then u_ε^2 , and argue in the same way for u_ε^3 and u_ε^4),

$$-v \leq R(v, w) \leq v, \quad -w \leq R(v, w) \leq w, \quad (10)$$

$$-v \leq S(v, w) \leq v, \quad -w \leq S(v, w) \leq w. \quad (11)$$

Additionally, it is convenient to control solution with the maximum principle. That is the case when there exists $u_M > 0$ such that

$$\frac{u - u_M}{2} \leq R\left(\frac{u + u_M}{2}, w\right) \leq \frac{u_M - u}{2}, \quad \forall w \geq 0, \forall 0 \leq u \leq u_M, \quad (12)$$

$$\frac{u - u_M}{2} \leq S\left(v, \frac{u + u_M}{2}\right) \leq \frac{u_M - u}{2}, \quad \forall v \geq 0, \forall 0 \leq u \leq u_M. \quad (13)$$

Finally, we want that the self-diffusion is always positive and that instabilities stem from the cross-terms

$$A_v > 0 \Leftrightarrow (d_1 + d_2) + (d_1 - d_2)R_v > 0, \quad B_w > 0 \Leftrightarrow (d_3 + d_4) + (d_3 - d_4)S_w > 0. \quad (14)$$

Again, for a given constant steady state, our goal is to prove equivalence between Turing instability for (6) and backward parabolicity for the cross-diffusion system (7). However, unlike the case system (1), for the 4×4 system, there does not exist entropy functionals in general, except in specific settings that we discuss in section 3.2.

1.3 Organisation of the paper

In section 2, we consider the system (1). We first prove that, being given a constant steady state, there is equivalence between Turing instabilities when ε is small enough and backward parabolicity in (5). Then, we study the different possible non-constant steady states with respect to ε . We exhibit a wide family of periodic steady states and study their isochronous character that may be induced by

F . Finally, we exhibit some classical entropy inequalities which give results in accordance with the criteria obtained on the function F for the existence of Turing instabilities.

In section 3, we extend our analysis to the system (6). We show that, again, there is equivalence between asymptotic Turing instabilities for ε small and the backward parabolicity for the cross-diffusion terms in the equation (8). The last part of this section is devoted to the existence of an entropy functional in specific settings.

2 Turing instability and analysis of Equation (1)

We begin with several aspects of the fast reaction in the system (1) under assumption (2). We plan to, on the one hand, understand the set of non constant steady states in dimension 1, and on the other hand, interpret our results with respect to some well-known entropy/Lyapunov structure on those equations [17].

2.1 Turing instability of system (1) and backward parabolic equation

To tackle the question of the equivalence between Turing instability and backward parabolicity for Equation (1), we consider a constant steady state $(\bar{u}, \bar{v})$, $\bar{v} = F(\bar{u})$ and we recall some basic observations and definitions.

Firstly, we consider the dynamical system

$$\frac{d}{dt} \begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} v - F(u) \\ F(u) - v \end{pmatrix}.$$

Because the quantity $M := u(t) + v(t)$ is constant, the solution is reduced to the simple equation $\frac{du}{dt} = M - u - F(u)$. Therefore, the state $(\bar{u}, \bar{v})$ is attractive for initial data satisfying $M = F(\bar{u}) + \bar{u}$ thanks to the assumption (2).

Around such a steady state $\bar{U}$, the linearized system reads

$$\begin{cases} \partial_t \delta u_\varepsilon - d_1 \Delta \delta u_\varepsilon = \varepsilon^{-1} [\delta v_\varepsilon - F'(\bar{u}) \delta u_\varepsilon], \\ \partial_t \delta v_\varepsilon - d_2 \Delta \delta v_\varepsilon = \varepsilon^{-1} [F'(\bar{u}) \delta u_\varepsilon - \delta v_\varepsilon]. \end{cases} \quad (15)$$

Its stability can be analyzed by decomposition on the spectral basis $(w_i)_{i \in \mathbb{N}}$ associated with the Laplacian

$$-\Delta w_i = \lambda_i w_i \quad \text{in } \Omega \quad \frac{\partial w_i}{\partial \nu} = 0 \quad \text{on } \partial\Omega.$$

Considering the projections $(\alpha_i, \beta_i) = \int_\Omega (\delta u_\varepsilon, \delta v_\varepsilon) w_i dx$, the system (15) is written as linear independent equations

$$\begin{cases} \frac{d\alpha_i}{dt} + d_1 \lambda_i \alpha_i = \varepsilon^{-1} [\beta_i - F'(\bar{u}) \alpha_i], \\ \frac{d\beta_i}{dt} + d_2 \lambda_i \beta_i = \varepsilon^{-1} [F'(\bar{u}) \alpha_i - \beta_i]. \end{cases} \quad (16)$$

Definition 2.1 *We say that the steady state $(\bar{u}, \bar{v})$ is asymptotically Turing unstable if, for ε small enough, it is Turing instable for the system (1), i.e., one of the components $i \in \mathbb{N}$ of the system (16) has a uniformly negative real part for ε small enough.*

The following result holds

Proposition 2.2 (Equivalence in the scalar case.) *We assume (2) and consider a steady state $(\bar{u}, \bar{v})$. It is asymptotically Turing unstable for (1), if and only if the equation (5) is backward parabolic that is if $A'(\bar{u} + F(\bar{u})) < 0$ or also*

$$d_1 + d_2 F'(\bar{u}) < 0. \quad (17)$$

Remark 2.3 *It will be clear from our proof below that this result still holds replacing $v - F(u)$ by a function $\phi(u, v)$ with adequate assumptions. Namely for $u \geq 0, v \geq 0$ one should impose $\phi(0, v) \geq 0$, $\phi(u, 0) \leq 0$, for some $u_M > 0$ $\phi(u_M, v) \leq 0$ and $\phi(u, u_M) \geq 0$, $\partial_v \phi(u, v) = 0$ and $\phi(u, F(u)) = 0$.*

Proof. To characterize asymptotic Turing instability we look for a value λ with $\text{Re} \lambda > 0$ such that $(\alpha_i(t), \beta_i(t)) = e^{\lambda t}(\bar{\alpha}_i, \bar{\beta}_i)$. This is written

$$\begin{cases} \lambda \bar{\alpha}_i + d_1 \lambda_i \bar{\alpha}_i = \varepsilon^{-1} [\bar{\beta}_i - F'(\bar{u}) \bar{\alpha}_i], \\ \lambda \bar{\beta}_i + d_2 \lambda_i \bar{\beta}_i = \varepsilon^{-1} [F'(\bar{u}) \bar{\alpha}_i - \bar{\beta}_i]. \end{cases}$$

This system can be reduced to $\lambda(\bar{\alpha}_i + \bar{\beta}_i) + \lambda_i(d_1 \bar{\alpha}_i + d_2 \bar{\beta}_i) = 0$ and

$$\lambda \bar{\alpha}_i + d_1 \lambda_i \bar{\alpha}_i = \varepsilon^{-1} \left[-\bar{\alpha}_i \frac{\lambda + \lambda_i d_1}{\lambda + \lambda_i d_2} - F'(\bar{u}) \bar{\alpha}_i \right].$$

A non-zero solution exists if and only if we can find a root to the polynomial

$$\mathbb{P}(\lambda) := \varepsilon \lambda^2 + \lambda(1 + F'(\bar{u}) + \varepsilon \lambda_i(d_1 + d_2)) + \varepsilon \lambda_i^2 d_1 d_2 + \lambda_i(d_1 + d_2 F'(\bar{u})).$$

If $d_1 + d_2 F'(\bar{u}) \geq 0$ this convex polynomial with positive value at $\lambda = 0$ and positive derivative at 0 cannot have a positive root and Turing instability is not possible.

If $d_1 + d_2 F'(\bar{u}) < 0$, choose any eigenvalue $\lambda_i > 0$ and ε small enough such that

$$2\varepsilon \lambda_i d_1 d_2 < |d_1 + d_2 F'(\bar{u})|.$$

Then, it is immediate to check that there is a positive root with the form $\lambda = \lambda_i \Lambda(\varepsilon \lambda_i)$ which depends smoothly on $\varepsilon \lambda_i$ with $\Lambda(0) = -A'(\bar{u} + F(\bar{u})) > 0$ and thus, asymptotic Turing instability holds. $\square$

2.2 Study of stationary states

We consider here the case of dimension 1 with $\Omega = (0, L)$ that is:

$$\begin{cases} \partial_t u_\varepsilon - d_1 \Delta u_\varepsilon = \varepsilon^{-1} (v_\varepsilon - F(u_\varepsilon)), \\ \partial_t v_\varepsilon - d_2 \Delta v_\varepsilon = -\varepsilon^{-1} (v_\varepsilon - F(u_\varepsilon)). \end{cases} \quad (18)$$

We assume that $F \in C^2$ and, for some $u_M > 0$,

$$\begin{cases} F'(\cdot) > -1, & F'(0) > 0, & F'(u) > 0 \quad \text{for } u \geq u_M, \\ F(u) < F(u_M) & \forall u < u_M, \end{cases} \quad (19)$$

Recalling the characterisation (17) of asymptotic Turing instability that we established previously, we consider the assumption

$$d_1 + d_2 F'(u) \geq 0, \quad \forall u \geq 0. \quad (20)$$

The following description for the stationary states of the system (18) holds.

Theorem 2.4 Assume $L > 0$ given. We have two possible outcomes

- If (20) is satisfied, then any stationary state of (18) is constant.
- If (20) is not satisfied, let $\bar{u}$ such that $\frac{d_1}{d_2} + F'(\bar{u}) < 0$ and $s_\varepsilon := \sqrt{\varepsilon d_1}$. Then, there exists $T(\bar{u})$ such that if $L \in T(\bar{u})s_\varepsilon\mathbb{N}$, there exists a non constant $T(\bar{u})s_\varepsilon$ periodic steady state of (18) with $u(0) = \bar{u}$.

Remark 2.5 Let us mention, that in the above Theorem, we only prove existence of periodic solution for discret parameters ε . This is because the function $\frac{d_1}{d_2}u + F(u)$ may be isochronous [3]. A typical example is the case where F is locally linear. Indeed, in this case, the solution u of (18), for initial data close enough to $\bar{u}$, are all proportional to

$$\cos(s_\varepsilon^{-1} \frac{2\pi}{T(\bar{u})} x).$$

In Theorem 2.6 we give a simple criteria on the function F in order to discard the isochronous setting.

Proof of Theorem 2.4. We first note that if (u, v) are stationary states of Equation (18) then

$$d_1 u'' + d_2 v'' = 0,$$

and so, using the Neumann boundary condition, we also have

$$d_1 u' + d_2 v' = 0.$$

In particular, there exists $\lambda \in \mathbb{R}$ such that

$$v = -\frac{d_1}{d_2}u + \lambda. \tag{21}$$

Plugging this in the equation satisfied by u we get

$$u'' = (d_1 \varepsilon)^{-1} \left(\frac{d_1}{d_2} u - \lambda + F(u) \right), \tag{22}$$

$$u'(0) = u'(L) = 0. \tag{23}$$

If (20) holds, then consider $w = u'$ and differentiate (22) to get

$$w'' = (d_1 \varepsilon)^{-1} w \left(\frac{d_1}{d_2} u + F'(u) \right).$$

Integrating the previous equality against w and using $w(0) = w(L) = 0$ and using (20) leads to

$$-\int_0^L |w'(x)|^2 dx \leq 0,$$

so that $w = 0$ and u is constant (and so is v).

Now assume on the contrary that (20) does not hold. For any $\lambda \in \mathbb{R}$, if u solves (22) and v is defined by (21), then (u, v) is a stationary solution of (18). In particular, if z solves

$$z'' = \frac{d_1}{d_2} z - \lambda + F(z), \tag{24}$$

$$z'(0) = z'(L/s_\varepsilon) = 0, \tag{25}$$

then if $u(x) := z(x/s_\varepsilon)$ and v is defined by (21), then (u, v) is a stationary solution of (18). If z is non constant and T -periodic, then u and v are non constant and $s_\varepsilon T$ -periodic. We thus only need to prove the existence of z , a non constant periodic solution of (24)-(25). Since we are refuting (20), we have the existence $\bar{u} > 0$ such that

$$\frac{d_1}{d_2} + F'(\bar{u}) < 0.$$

Define

$$\lambda := \frac{d_1}{d_2} \bar{u} + F(\bar{u}),$$

this means that $Y := (z, z')$ solves the Hamiltonian system defined by the vector field $\Theta(y_1, y_2) = (y_2, \mu(y_1))$, where

$$\mu(y_1) := \frac{d_1}{d_2} y_1 - \lambda + F(y_1).$$

We infer from Propositions A.1 of the Appendix the existence of (non constant) periodic solutions for our system. In order to conclude, we need to get a period T such that $L \in s_\varepsilon T\mathbb{N}$. This ends the proof of Theorem 2.4. $\square$

2.3 Continuum set of parameters with periodic solutions

We now prove that there exists a continuum of periodic solutions with fixed total mass, assuming the following stronger assumption on F : there exists a value U in the unstable range, satisfying the conditions

$$-1 < F'(U) < -\frac{d_1}{d_2}, \quad F''(U) \neq 0, \quad U + F(U) = M^0/L. \quad (26)$$

More precisely, the following theorem holds.

Theorem 2.6 *Assume that F is smooth and that (26) holds. For all $n \in \mathbb{N}^*$, there are non-constant periodic solutions with n (minimal) periods and with mass M^0 , defined when ε belongs to a small interval $[\varepsilon_n, \varepsilon_n^+]$, where $\varepsilon_n = \frac{1}{d_1} \left(\frac{L}{n} \frac{\omega(U)}{2\pi} \right)^2$, $\varepsilon_n < \varepsilon_n^+$ and $\omega(U) = \sqrt{-(\frac{d_1}{d_2} + F'(U))}$.*

Proof of Theorem 2.6. The idea of the proof of Theorem 2.6 is to consider a small perturbation of an unstable constant steady state $\bar{u}$ and to make some Taylors expansions in order to construct, modulo small order terms, explicitly the solution of (24)-(25). This allow us to compute the Taylor expansion of the period and then to conclude the proof of our Theorem.

Let us first introduce the following notations

$$y = x/\sqrt{\varepsilon d_1}, \quad w(y) = u(x), \quad V(u) = \frac{d_1}{d_2} \frac{u^2}{2} + G(u), \quad G(u) = \int_0^u F(s) ds.$$

Then, we consider two parameters $(\bar{u}, \delta)$ with $\delta > 0$ small and $\bar{u}$ close to U . We choose $\lambda = V'(\bar{u})$, the equation is then written

$$\begin{cases} w'' = V'(w) - V'(\bar{u}), & y \in \mathbb{R} \\ w'(0) = 0, \quad w(0) = \bar{u} - \delta. \end{cases} \quad (27)$$

By opposition to the harmonic oscillator, we consider a value U such that the condition (26) holds, which means, using the notation $V''' = V^{(3)}$,

$$V''(U) < 0, \quad V^{(3)}(U) \neq 0, \quad \text{and we set } \omega(U) = \sqrt{-V''(U)}. \quad (28)$$

We have $M^0 = [U + F(U)]L = (1 - \frac{d_1}{d_2})U + V'(U)$. We are then reduced to find periodic solutions w , with a period $T := T(\bar{u}, \delta)$ for which a multiple $n \in N^*$ gives

$$nT\sqrt{\varepsilon d_1} = L, \quad (29)$$

and for which the mass conservation gives

$$n\sqrt{\varepsilon d_1} \left[\left(1 - \frac{d_1}{d_2}\right) \int_0^T w + T V'(\bar{u}) \right] = M^0$$

and thus

$$\left(1 - \frac{d_1}{d_2}\right) \frac{1}{T} \int_0^T w + V'(\bar{u}) = \frac{M^0}{L}. \quad (30)$$

Our claim is that, when ε varies in an appropriate interval, we can select a one parameter family of values $(\bar{u}(\delta), \delta)$ around $(U, 0)$ where both conditions on the mass M^0 in (30) and the period (29) are fulfilled.

Expansion of the solution and of the period. The following Lemma holds

Lemma 2.7 *Let $\bar{u}$ be an unstable constant steady state and let $T(\bar{u}, \delta)$ be the smallest period of the solution of Equation (27). Assume that T is $\mathcal{C}^3$ with respect to the variable δ . Then the following Taylor expansion holds*

$$T(\bar{u}, \delta) = \frac{2\pi}{\omega} \left(1 + \delta^2 \frac{(V^{(3)}(\bar{u}))^2}{24\omega^4} \right) + \mathcal{O}(\delta^3).$$

Proof of Lemma 2.7. We first compute an approximation of Equation (27) as follows. We set $z = w - \bar{u}$, and the equation (27) is written

$$\begin{cases} z'' = V'(z + \bar{u}) - V'(\bar{u}) = V''(\bar{u})z + \frac{V^{(3)}(\bar{u})}{2}z^2 + \frac{V^{(4)}(\bar{u})}{6}z^3 + \mathcal{O}(\delta^4) \\ z'(0) = 0, \quad z(0) = -\delta. \end{cases}$$

We now simplify notations ignoring the dependency of $\bar{u}$ in the formulas. We expand, departing from our knowledge of the first order term, under the form

$$z = -\delta \cos(\omega y) + \delta^2 z_1 + \delta^3 z_3 + \mathcal{O}(\delta^4).$$

At second order, z_1 is the solution of

$$z_1'' = -\omega^2 z_1 + \frac{1}{2} V^{(3)} \cos(\omega y)^2, \quad z_1(0) = z_1'(0) = 0.$$

Using the identity $\cos(\omega y)^2 = \frac{1}{2} + \frac{\cos(2\omega y)}{2}$, we deduce that

$$z_1'' = -\omega^2 z_1 + \frac{1}{2} V^{(3)} \left(\frac{1}{2} + \frac{\cos(2\omega y)}{2} \right).$$

Setting $z_2 := z_1 - \frac{V^{(3)}}{4\omega^2}$, we obtain

$$z_2'' = -\omega^2 z_2 + \frac{V^{(3)}}{4} \cos(2\omega y), \quad z_2(0) = -\frac{V^{(3)}}{4\omega^2}, \quad z_2'(0) = 0,$$

$$z_2(y) = B_1 \cos(\omega y) + B_2 \cos(2\omega y), \quad B_1 = -\frac{V^{(3)}}{6\omega^2}, \quad B_2 = -\frac{V^{(3)}}{12\omega^2}.$$

At third order, z_3 is the solution of the equation

$$z_3'' = -\omega^2 z_3 - \frac{V^{(3)}}{2} z_1 \cos(\omega y) - \frac{V^{(4)}}{6} \cos^3(\omega y), \quad z_3(0) = z_3'(0) = 0.$$

We then deduce that there exists α, β, γ such that

$$z_3(y) = -\frac{B_1 V^{(3)}}{4\omega^2} + \alpha \cos(\omega y) + \beta \cos(2\omega y) + \delta \cos(3\omega y),$$

that is

$$z_3(y) = \frac{1}{24} \left(\frac{V^{(3)}}{\omega^2} \right)^2 + \alpha \cos(\omega y) + \beta \cos(2\omega y) + \delta \cos(3\omega y).$$

We are now able to compute the Taylor expansion of the period T with respect to δ . Integrating Equation (27) between 0 and $T(\delta, \bar{u})$, and to simplify notations we simply use T , we deduce that

$$0 = \int_0^T [V'(w(y)) - V'(\bar{u})] dy.$$

We insert the Taylor expansion of $V'(w - \bar{u} + \bar{u})$

$$V'(w) - V'(\bar{u}) = V''(\bar{u})z + \frac{1}{2}V^{(3)}(\bar{u})z^2 + \frac{1}{6}V^{(4)}(\bar{u})z^3 + \mathcal{O}(\delta^4).$$

and thus we arrive at

$$\begin{aligned} \mathcal{O}(\delta^4) = & V'' \int_0^T \left[-\delta \cos(\omega y) + \delta^2 [B_1 \cos(\omega y) + B_2 \cos(2\omega y) + \frac{V^{(3)}}{4\omega^2}] + \delta^3 z_3 \right] dy \\ & + \delta^2 \frac{V^{(3)}}{2} \int_0^T \cos^2(\omega y) dy + \delta^3 V^{(3)} \int_0^T \cos(\omega y) z_1 dy + \delta^3 \frac{V^{(4)}}{6} \int_0^T \cos^3(\omega y) dy. \end{aligned}$$

Next, we set

$$T(\delta) = T(0) + T'(0)\delta + T''(0)\frac{\delta^2}{2} + \mathcal{O}(\delta^3)$$

and the first order term gives

$$T(0) = \frac{2\pi}{\omega}.$$

Next, we use that for all $n \geq 1$

$$\int_0^{T(0)} \cos(n\omega y) dy = 0,$$

and we deduce that

$$\begin{aligned}
\mathcal{O}(\delta^3) &= V'' \int_0^T \left[-\cos(\omega y) + \delta [B_1 \cos(\omega y) + B_2 \cos(2\omega y) + \frac{V^{(3)}}{4\omega^2}] + \delta^2 \frac{1}{24} \left(\frac{V^{(3)}}{\omega^2} \right)^2 \right] dy \\
&\quad + \delta \frac{V^{(3)}}{2} \int_0^T \cos^2(\omega y) dy \\
&= V'' \int_0^T [-\cos(\omega y) + \delta [B_1 \cos(\omega y) + B_2 \cos(2\omega y)]] dy + \delta T \frac{V'' V^{(3)}}{4\omega^2} \\
&\quad + \delta^2 T(0) \frac{V''}{24} \left(\frac{V^{(3)}}{\omega^2} \right)^2 + \delta \frac{V^{(3)}}{2} \int_0^T \cos^2(\omega y) dy.
\end{aligned}$$

Next, we arrive at

$$\begin{aligned}
\mathcal{O}(\delta^3) &= V'' \int_{T(0)}^T [-\cos(\omega y) + \delta [B_1 \cos(\omega y) + B_2 \cos(2\omega y)]] dy - \delta T \frac{V^{(3)}}{4} \\
&\quad - \delta^2 T(0) \frac{1}{24} \left(\frac{V^{(3)}}{\omega} \right)^2 + \delta \frac{V^{(3)}}{2} \left[\frac{T(0)}{2} + \int_{T(0)}^T \cos^2(\omega y) dy \right]
\end{aligned}$$

and because $\cos(\omega y) \approx 1 - \frac{\omega(y-T(0))^2}{2}$ near $T(0)$, we find

$$\begin{aligned}
\mathcal{O}(\delta^3) &= V'' \int_{T(0)}^T [-1 + \delta [B_1 + B_2]] dy - \delta T \frac{V^{(3)}}{4} \\
&\quad - \delta^2 T(0) \frac{1}{24} \left(\frac{V^{(3)}}{\omega} \right)^2 + \delta \frac{V^{(3)}}{2} \left[\frac{T(0)}{2} + \int_{T(0)}^T dy \right] \\
&= V'' \left[-\delta T'(0) - \frac{\delta^2}{2} T''(0) + T'(0) \delta^2 [B_1 + B_2] \right] - \delta^2 T'(0) \frac{V^{(3)}}{4} \\
&\quad - \delta^2 T(0) \frac{1}{24} \left(\frac{V^{(3)}}{\omega} \right)^2 + \delta^2 \frac{V^{(3)}}{2} T'(0).
\end{aligned}$$

The first order term implies that

$$T'(0) = 0.$$

and the second order term gives

$$T''(0) = T(0) \frac{(V^{(3)})^2}{12\omega^4}.$$

This ends the proof of Lemma 2.7. □

Mass conservation. We need again to expand the solution w itself. We write

$$w'' = -\omega^2(w(y) - \bar{u}) + O(\delta^2). \tag{31}$$

Therefore we can expand

$$w = \bar{u} - \delta \cos(\omega y) + O(\delta^2).$$

Integrating the equation (31) between 0 and $\frac{T}{2}$, we find

$$0 = -\omega^2 \int_0^{\frac{T}{2}} [w(y) - \bar{u}] dy + \frac{1}{2} V^{(3)}(\bar{u}) \int_0^{\frac{T}{2}} [w(y) - \bar{u}]^2 dy + O(\delta^3),$$

that is also written

$$\begin{aligned} \omega^2 \int_0^{\frac{T}{2}} [w(y) - \bar{u}] dy &= \frac{\delta^2}{2} V^{(3)}(\bar{u}) \int_0^{\frac{T}{2}} \cos(\omega y)^2 dy + O(\delta^3) \\ &= \frac{\delta^2}{2} \frac{V^{(3)}(\bar{u})}{\omega} \int_0^{\omega \frac{T}{2}} \cos(y')^2 dy' + O(\delta^3) \\ &= \frac{\delta^2}{2} \frac{V^{(3)}(\bar{u})}{\omega} \underbrace{\int_0^{\pi} \cos(y')^2 dy'}_{=\pi/2} + O(\delta^3). \end{aligned}$$

Therefore the mass condition (30) can be written successively as

$$\begin{aligned} (1 - \frac{d_1}{d_2}) \frac{2}{T} \int_0^{T/2} (w - \bar{u}) + [(1 - \frac{d_1}{d_2}) \bar{u} + V'(\bar{u})] &= \frac{M^0}{L}, \\ (1 - \frac{d_1}{d_2}) \delta^2 \frac{V^{(3)}(\bar{u})}{T \omega^3} \frac{\pi}{2} + O(\delta^3) + \bar{u} + F(\bar{u}) &= U + F(U). \end{aligned}$$

Because $u \mapsto u + F(u)$ is locally invertible around U , and because δ is small, this means that we can choose $\bar{u}(\delta)$ according to this expression and get

$$\bar{u}(\delta) = U - \frac{\delta^2}{1 + F'(U)} (1 - \frac{d_1}{d_2}) \frac{V^{(3)}(U)}{\omega(U)^2} \frac{1}{4} + O(\delta^3).$$

Conclusion According to Lemma 2.7, the intervals of values ϵ are finally given by

$$\begin{aligned} \sqrt{\epsilon d_1} &= \frac{L}{n} \frac{\omega(\bar{u})}{2\pi} \left[1 + \frac{\delta^2 (V^{(3)}(\bar{u}))^2}{24 \omega(\bar{u})^4} + O(\delta^3) \right] \\ &= \frac{L}{n} \frac{\omega(U)}{2\pi} \left[1 + \delta^2 \frac{(V^{(3)}(U))^2}{(\omega(U))^2} \left(\frac{1}{24 (\omega(U))^2} + \frac{L(1 - \frac{d_1}{d_2})}{16 n \pi (1 + F'(U)) \omega(U)} \right) + O(\delta^3) \right]. \end{aligned}$$

This ends the proof of Theorem 2.6. □

2.4 Interpretation *via* entropy functionals

In this part, we again consider equation on a regular bounded domain $\Omega \subset \mathbb{R}^d$

$$\begin{cases} \partial_t u_\epsilon - d_1 \Delta u_\epsilon = \epsilon^{-1} (v_\epsilon - F(u_\epsilon)), \\ \partial_t v_\epsilon - d_2 \Delta v_\epsilon = -\epsilon^{-1} (v_\epsilon - F(u_\epsilon)). \end{cases}$$

Following [17], several entropy functionals allow to tackle, on the one hand the asymptotic dynamic of the solution and on the other hand the fast reaction limit, in the case where no Turing instabilities may appear. More precisely, we have the following three keys equality

Let G be an antiderivative of F . Multiplying the equation on u_ε by $F(u_\varepsilon)$ and on v_ε by v_ε , we have

$$\begin{aligned} \frac{d}{dt} \int_{\Omega} \left(G(u_\varepsilon)(x, t) + \frac{1}{2} v_\varepsilon^2(x, t) \right) dx &= -d_1 \int_{\Omega} F'(u_\varepsilon) |\nabla u_\varepsilon|^2 dx - d_2 \int_{\Omega} |\nabla v_\varepsilon|^2 dx \\ &\quad - \frac{1}{\varepsilon} \int_{\Omega} (v_\varepsilon - F(u_\varepsilon))^2 dx. \end{aligned} \quad (32)$$

Multiplying the equation on $w_\varepsilon = u_\varepsilon + v_\varepsilon$ by w_ε , we find that

$$\frac{d}{dt} \int_{\Omega} \frac{w_\varepsilon^2}{2} dx = - \int_{\Omega} \nabla w_\varepsilon \cdot (d_1 \nabla u_\varepsilon + d_2 \nabla v_\varepsilon) dx. \quad (33)$$

Multiplying the equation on u_ε by Δu_ε , we find that

$$\frac{d}{dt} \int_{\Omega} \frac{|\nabla u_\varepsilon|^2}{2} dx = -d_1 \int_{\Omega} (\Delta u_\varepsilon)^2 dx + \frac{1}{\varepsilon} \left(\int_{\Omega} \nabla u_\varepsilon \cdot \nabla v_\varepsilon dx - \int_{\Omega} F'(u_\varepsilon) |\nabla u_\varepsilon|^2 dx \right), \quad (34)$$

and that

$$\frac{d}{dt} \int_{\Omega} \frac{|\nabla u_\varepsilon|^2}{2} dx = -d_1 \int_{\Omega} (\Delta u_\varepsilon)^2 dx - \frac{1}{\varepsilon} \left(\int_{\Omega} (v_\varepsilon - F(u_\varepsilon)) \Delta u_\varepsilon dx \right). \quad (35)$$

From this, we deduce the following proposition, taken from [17] (see also Appendix B, for more details)

Proposition 2.8 *Combining equalities (32)–(35), the following equality holds*

$$\begin{aligned} \frac{d}{dt} \int_{\Omega} \left(G(u_\varepsilon)(x, t) + \frac{1}{2} v_\varepsilon^2(x, t) + \frac{\varepsilon d_1}{2} |\nabla u_\varepsilon|^2 + \frac{\varepsilon d_1^2}{4(d_2 - d_1)} w_\varepsilon^2 \right) dx &= \\ -\varepsilon \int_{\Omega} \left(d_1 \Delta u_\varepsilon + \frac{1}{\varepsilon} (v_\varepsilon - F(u_\varepsilon)) \right)^2 dx &- \frac{1}{d_2 - d_1} \int_{\Omega} (d_1 \nabla u_\varepsilon + d_2 \nabla v_\varepsilon)^2 dx. \end{aligned} \quad (36)$$

Combining equalities (32) and (33), the following equality holds for $d_2 > d_1$

$$\begin{aligned} \frac{d}{dt} \int_{\Omega} \left(G(u_\varepsilon)(x, t) + \frac{1}{2} v_\varepsilon^2(x, t) + \frac{d_1}{d_2 - d_1} w_\varepsilon^2 \right) dx &= -d_1 \int_{\Omega} \left(F'(u_\varepsilon) + \frac{d_1}{d_2} \right) |\nabla u_\varepsilon|^2 dx \\ &\quad - \frac{d_1 + d_2}{d_2(d_2 - d_1)} \int_{\Omega} (d_1 \nabla u_\varepsilon + d_2 \nabla v_\varepsilon)^2 dx - \frac{1}{\varepsilon} \int_{\Omega} (v_\varepsilon - F(u_\varepsilon))^2 dx. \end{aligned} \quad (37)$$

and for $d_1 > d_2$

$$\begin{aligned} \frac{d}{dt} \int_{\Omega} \left(G(u_\varepsilon)(x, t) + \frac{1}{2} v_\varepsilon^2(x, t) + \frac{d_2}{d_1 - d_2} w_\varepsilon^2 \right) dx &= -d_1 \int_{\Omega} \left(F'(u_\varepsilon) + \frac{d_2}{d_1} \right) |\nabla u_\varepsilon|^2 dx \\ &\quad - \frac{d_1 + d_2}{d_2(d_1 - d_2)} \int_{\Omega} (d_1 \nabla u_\varepsilon + d_2 \nabla v_\varepsilon)^2 dx - \frac{1}{\varepsilon} \int_{\Omega} (v_\varepsilon - F(u_\varepsilon))^2 dx. \end{aligned} \quad (38)$$

These inequalities have standard consequences in term of behaviors of solutions that we recall and complete with a larger range of validity for the parameters.

Long time asymptotic, $\varepsilon > 0$ fixed. Using the energy dissipation, the equality (36) ensures that, asymptotically, as $t \rightarrow \infty$, the solutions converge to a stationary state. We refer to [15, 16] for more precise results on this topic.

The limit $\varepsilon \rightarrow 0$, $d_1 \neq d_2$. The equalities (37), (38) are useful in the two cases when $d_2 > d_1$ and $\frac{d_1}{d_2} + F'(\cdot) \geq c_o > 0$ or $d_1 > d_2$ and $\frac{d_2}{d_1} + F'(\cdot) \geq c_o > 0$. On the one hand, it shows that the solution necessary converges in long time to a constant stationary state in accordance with Theorem 2.4.

On the other hand, these equalities provide us with uniform bounds, with respect to ε , on the derivatives of u and v . They give the existence of a constant $C > 0$ independent of $\varepsilon > 0$ such that

$$\int_{t=0}^{+\infty} \int_{\Omega} |\nabla u_{\varepsilon}|^2 + |\nabla v_{\varepsilon}|^2 dx dt < C.$$

The situation is exactly the same as in [4] which treats the case $F'(\cdot) \geq 0$. Therefore, we can extend the result in [4], with the same proof, to obtain the

Theorem 2.9 *Assume $d_1 < d_2$ and $\frac{d_1}{d_2} + F'(\cdot) \geq c_o > 0$, or $d_1 > d_2$ and $\frac{d_2}{d_1} + F'(\cdot) \geq c_o > 0$. As $\varepsilon \rightarrow 0$, $w_{\varepsilon} = u_{\varepsilon} + v_{\varepsilon}$ converges a.e. to a function w that satisfies the equation*

$$\begin{cases} \partial_t w - \Delta A(w) = 0, & x \in \Omega, t \geq 0 \\ \frac{\partial w}{\partial \nu} = 0 & \text{on } \partial\Omega, \end{cases} \quad (39)$$

where A is defined in Section 1.1 and is written

$$A(w) := d_1 u + d_2 F(u), \text{ with } w = u + F(u).$$

Let us mention that the question of convergence of u_{ε} , v_{ε} , when $\varepsilon \rightarrow 0$, in the case where (20) is not satisfied, is very difficult to tackle because of the oscillations of size $\frac{1}{\sqrt{d_1 \varepsilon}}$ that may appear as shown in Section 2.2.

The case $d_1 = d_2$ is simpler but requires a specific proof because w_{ε} satisfies the heat equation.

3 A 2×2 cross diffusion system

In Section 2, in the context of a system of two reaction-diffusion equations, we established an equivalence between Turing instability for a steady state of (1), and ill-posedness (*e.g.* “backward parabolicity”) of the corresponding fast reaction limit equation. Here, we aim at exhibiting a class of 4×4 reaction-diffusion systems for which the asymptotic $\varepsilon \rightarrow 0$ produces a full 2×2 cross diffusion systems and in which the equivalence Turing instability / backward parabolicity holds as before.

We use the notations and assumptions of section 1.2.

3.1 Turing instabilities and backward cross-diffusion equation

Here again, we obtain the direct analog of the “backward parabolicity” property for the cross diffusion system (8), that is the negativity of the Jacobian of the matrix M defined below. More precisely we have the following result

Proposition 3.1 Assume (14). Then, a linearly constant steady state $\bar{U} = {}^t(\bar{u}^1, \bar{u}^2, \bar{u}^3, \bar{u}^4)$ is asymptotically Turing unstable for (6) if and only if $\det M(\bar{V}) < 0$, where

$$M = \begin{pmatrix} A_v & A_w \\ B_v & B_w \end{pmatrix}, \quad \bar{V} := \frac{1}{2} \begin{pmatrix} \bar{u}^1 + \bar{u}^2 \\ \bar{u}^3 + \bar{u}^4 \end{pmatrix}.$$

In other words, Turing instability is equivalent to backward parabolicity of the cross-diffusion system.

We recall that, because we assume self-diffusion is positive in (14), that means $A_v > 0$, $B_w > 0$, the matrix M has always an eigenvalue with positive real part; the cross-diffusion system cannot be fully backward with two negative eigenvalues.

Proof of Proposition 3.1. We define the change of variables

$$v_\varepsilon = \frac{u_\varepsilon^1 + u_\varepsilon^2}{2}, \quad w_\varepsilon = \frac{u_\varepsilon^3 + u_\varepsilon^4}{2}, \quad y_\varepsilon = \frac{d_1 u_\varepsilon^1 + d_2 u_\varepsilon^2}{2}, \quad z_\varepsilon = \frac{d_3 u_\varepsilon^3 + d_4 u_\varepsilon^4}{2}.$$

We find that

$$u_\varepsilon^1 = 2 \frac{d_2 v_\varepsilon - y_\varepsilon}{d_2 - d_1} \text{ and } u_\varepsilon^3 = 2 \frac{d_4 w_\varepsilon - z_\varepsilon}{d_4 - d_3}.$$

With the new variables, we obtain the following system of equations

$$\begin{cases} \partial_t y_\varepsilon = (d_2 + d_1) \Delta y_\varepsilon - d_1 \Delta v_\varepsilon + \frac{(d_1 - d_2)}{2\varepsilon} \left(R(v_\varepsilon, w_\varepsilon) - v_\varepsilon \frac{(d_1 + d_2)}{(d_2 - d_1)} + \frac{2y_\varepsilon}{(d_2 - d_1)} \right), \\ \partial_t v_\varepsilon = \Delta y_\varepsilon, \\ \partial_t z_\varepsilon = (d_4 + d_3) \Delta z_\varepsilon - d_3 \Delta w_\varepsilon + \frac{(d_3 - d_4)}{2\varepsilon} \left(S(v_\varepsilon, w_\varepsilon) - w_\varepsilon \frac{(d_3 + d_4)}{(d_4 - d_3)} + \frac{2z_\varepsilon}{(d_4 - d_3)} \right), \\ \partial_t w_\varepsilon = \Delta z_\varepsilon, \end{cases}$$

and so

$$\begin{cases} \partial_t y_\varepsilon = (d_2 + d_1) \Delta y_\varepsilon - d_1 \Delta v_\varepsilon + \frac{1}{\varepsilon} (A(v, w) - y_\varepsilon), \\ \partial_t v_\varepsilon = \Delta y_\varepsilon, \\ \partial_t z_\varepsilon = (d_4 + d_3) \Delta z_\varepsilon - d_3 \Delta w_\varepsilon + \frac{1}{\varepsilon} (B(v, w) - z_\varepsilon), \\ \partial_t w_\varepsilon = \Delta z_\varepsilon. \end{cases}$$

The linearized equation, around a stationary state $(\bar{v}, \bar{w}, \bar{y}, \bar{z})$, is given by

$$\begin{cases} \partial_t y_\varepsilon = (d_2 + d_1) \Delta y_\varepsilon - d_1 \Delta v_\varepsilon + \frac{1}{\varepsilon} (A_v(\bar{v}, \bar{w}) v_\varepsilon + A_w(\bar{v}, \bar{w}) w_\varepsilon) - \frac{y_\varepsilon}{\varepsilon}, \\ \partial_t v_\varepsilon = \Delta y_\varepsilon, \\ \partial_t z_\varepsilon = (d_4 + d_3) \Delta z_\varepsilon - d_3 \Delta w_\varepsilon + \frac{1}{\varepsilon} (B_v(\bar{v}, \bar{w}) v_\varepsilon + B_w(\bar{v}, \bar{w}) w_\varepsilon) - \frac{z_\varepsilon}{\varepsilon}, \\ \partial_t w_\varepsilon = \Delta z_\varepsilon. \end{cases} \quad (40)$$

Now, we decompose each solution of (40) with respect to the eigenfunctions E_i of the Laplacian associated to the eigenvalues $\lambda_i \leq 0$, that is we write

$$v_\varepsilon = \sum_{i=0}^{+\infty} E_i v_\varepsilon^i(t), \quad w_\varepsilon = \sum_{i=0}^{+\infty} E_i w_\varepsilon^i(t), \quad y_\varepsilon = \sum_{i=0}^{+\infty} E_i y_\varepsilon^i(t), \quad z_\varepsilon = \sum_{i=0}^{+\infty} E_i z_\varepsilon^i(t).$$

We find that

$$\frac{d}{dt} \begin{pmatrix} v_\varepsilon^i \\ w_\varepsilon^i \\ y_\varepsilon^i \\ z_\varepsilon^i \end{pmatrix} = M_i \begin{pmatrix} v_\varepsilon^i \\ w_\varepsilon^i \\ y_\varepsilon^i \\ z_\varepsilon^i \end{pmatrix}, \quad M_i = \begin{pmatrix} 0 & 0 & \lambda_i & 0 \\ 0 & 0 & 0 & \lambda_i \\ a^{31} & a^{32} & a^{33} & 0 \\ a^{41} & a^{42} & 0 & a^{44} \end{pmatrix}$$

with

$$\begin{aligned} a^{31} &= -d_1\lambda_i + \frac{1}{\varepsilon}A_v, & a^{32} &= \frac{1}{\varepsilon}A_w, & a^{33} &= (d_1 + d_2)\lambda_i - \frac{1}{\varepsilon}, \\ a^{41} &= \frac{1}{\varepsilon}B_v, & a^{42} &= -d_3\lambda_i + \frac{1}{\varepsilon}B_w, & a^{44} &= (d_3 + d_4)\lambda_i - \frac{1}{\varepsilon}. \end{aligned}$$

Let us mention that, because $\lambda_i < 0$, $A_v > 0$, $B_w > 0$ we have

$$a^{31} > 0, \quad a^{33} < 0, \quad a^{42} > 0, \quad a^{44} < 0.$$

We find that

$$\begin{aligned} P(\eta) &:= \text{Det}(A_i - \eta I_4) \\ &= \eta^4 + \eta^3(-a^{33} - a^{44}) + \eta^2(a^{33}a^{44} - \lambda_i(a^{42} + a^{31})) + \eta\lambda_i(a^{31}a^{44} + a^{42}a^{33}) + \lambda_i^2(a^{31}a^{42} - a^{41}a^{32}). \end{aligned}$$

We have

$$a^{31}a^{42} - a^{41}a^{32} < 0 \Leftrightarrow (A_vB_w - B_vA_w) < 0 \quad \text{if } \varepsilon \text{ small enough,}$$

hence, we obtain for $\varepsilon > 0$ small enough, that P has a positive root if and only if $(A_vB_w - B_vA_w) < 0$ which ends the proof of Proposition 3.1. $\square$

3.2 Entropy functional

In general, we could not find an entropy functional for the system (6). However, when there exists two functions ϕ_1 and ϕ_2 such that

$$\phi_1(w) + \int_0^v A(y, w)dy = \phi_2(v) + \int_0^w B(v, y)dy := \Phi(v, w), \quad (41)$$

the following proposition holds

Proposition 3.2 *Assume that assumption (41) holds. Let*

$$E_1(t) := \frac{1}{2} \left(\|\nabla y\|_{L^2(\Omega)}^2 + \|\nabla z\|_{L^2(\Omega)}^2 + d_1\|\nabla v\|_{L^2(\Omega)}^2 + d_3\|\nabla w\|_{L^2(\Omega)}^2 \right) + \frac{1}{\varepsilon} \int_{\Omega} \Phi(t, x)dx.$$

Then, the following estimate holds

$$\frac{d}{dt}E_1(t) = -\frac{1}{\varepsilon} \left(\|\nabla y\|_{L^2(\Omega)}^2 + \|\nabla z\|_{L^2(\Omega)}^2 \right) - (d_1 + d_2)\|\Delta y\|_{L^2(\Omega)}^2 - (d_3 + d_4)\|\Delta z\|_{L^2(\Omega)}^2.$$

Proof of Proposition 3.2. We work on the system (40). Multiplying the equation on y_ε by Δy_ε and the equation on z_ε by Δz_ε , and the equations on v and w by Φ , we find that

$$\begin{aligned} \frac{d}{dt} & \left(\frac{1}{2}(\|\nabla y\|_{L^2(\Omega)}^2 + \|\nabla z\|_{L^2(\Omega)}^2 + d_1\|\nabla v\|_{L^2(\Omega)}^2 + d_3\|\nabla w\|_{L^2(\Omega)}^2) + \frac{1}{\varepsilon} \int_{\Omega} \Phi(t, x)dx \right) \\ &= -\frac{1}{\varepsilon} \left(\|\nabla y\|_{L^2(\Omega)}^2 + \|\nabla z\|_{L^2(\Omega)}^2 \right) - (d_1 + d_2)\|\Delta y\|_{L^2(\Omega)}^2 - (d_3 + d_4)\|\Delta z\|_{L^2(\Omega)}^2. \end{aligned}$$

$\square$

A Hamiltonian system

We give another approach to the existence of periodic solutions in the context of Theorem 2.6.

We consider $\mu \in \mathcal{C}^1(\mathbb{R})$ and the vector field $\Theta : \mathbb{R}^2 \rightarrow \mathbb{R}^2$

$$\Theta \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} = \begin{pmatrix} y_2 \\ \mu(y_1) \end{pmatrix}.$$

We assume appropriate growth conditions on μ so that, for any $Y_0 \in \mathbb{R}^2$ the system

$$\begin{aligned} Y'(t) &= \Theta(Y(t)), \\ Y(0) &= Y_0, \end{aligned}$$

admits a global solution. We denote by $\Phi_t(Y_0)$ the corresponding flow.

Proposition A.1 *If $\mu'(\bar{u}) < 0 = \mu(\bar{u})$ for some real number $\bar{u}$, there exists a neighborhood V of $(\bar{u}, 0)$ such that for any $Y_0 \in V \setminus (\bar{u}, 0)$, $t \mapsto \Phi_t(Y_0)$ is periodic and non constant.*

Proof. By assumption the point $\bar{Y} := (\bar{u}, 0)$ is an equilibrium for our system. A straightforward computation shows that if $\gamma' = \mu$ and $t \mapsto (y_1(t), y_2(t))$ is a solution, then the following function is constant

$$t \mapsto \frac{y_2(t)^2}{2} - \gamma(y_1(t)).$$

The corresponding Hamiltonian H satisfies $\nabla H(y_1, y_2) = (-\mu(y_1), y_2)$ and

$$D^2 H(y_1, y_2) = \begin{pmatrix} -\mu'(y_1) & 0 \\ 0 & 1 \end{pmatrix}.$$

In particular $\nabla H(\bar{Y}) = 0$ and $D^2 H(\bar{Y}) > 0$: H has a local strict minimum at $\bar{Y}$. Take W a neighborhood of $\bar{Y}$ on which $Y \neq \bar{Y} \Rightarrow H(Y) > H(\bar{Y})$ and also $\mu(y_1)(y_1 - \bar{u}) < 0$, the latter being possible thanks to the assumption $\mu'(\bar{u}) < 0 = \mu(\bar{u})$. Consider a closed circle $\mathcal{C} \subset W$ around $\bar{Y}$. If $\delta = \min_{\mathcal{C}} H$, by continuity we have the existence of a neighborhood V of $\bar{Y}$ on which $\sup_V H < \delta$. For any $Y_0 \in V$ the map $t \mapsto H(\Phi_t(Y_0))$ is constant, in particular $\Phi_t(Y_0)$ may not cross $\mathcal{C}$. If D is the open disk delimited by $\mathcal{C}$ we have just proved $Y_0 \in V \Rightarrow \{\Phi_t(Y_0) : t \geq 0\} \subset D$.

Now if $Y_0 \in V$ and $\Phi_t(Y_0) = (y_1(t), y_2(t))$, it is not possible to have $y_1 > \bar{u}$ near $+\infty$. Indeed, recall that near $+\infty$ a bounded concave nonincreasing function is constant. In particular, if $y_1 > \bar{u}$ near $+\infty$, then $y_1'' = y_2 = \mu(y_1) < 0$ near infinity, so that y_1 is concave and non constant ; since $\{\Phi_t(Y_0) : t \geq 0\} \subset D$, y_1 must be increasing. But then the same argument applies on y_1' which is nonincreasing (because $y_1'' < 0$) and concave (because $y_1'' = \mu(y_1)$ is decreasing). In a similar way, we cannot have $y_1(t) < \bar{u}$ near $+\infty$.

We eventually proved that $t \mapsto y_1(t)$ takes the value $\bar{u}$ infinitely many times. But because of the Hamiltonian equation, for a given value of $y_1(t)$, there are at most two possible choices for $y_2(t)$: the map $t \mapsto (y_1(t), y_2(t))$ may not be injective and is hence periodic. Since Θ vanishes only at $\bar{Y}$ on V , $t \mapsto \Phi_t(Y_0)$ is non constant if $Y_0 \neq \bar{Y}$.

Proposition A.2 *Under the Assumptions of Proposition A.1, for a possibly smaller neighborhood V , the following holds: for any $z_0 < \bar{u}$ such that $(z_0, 0) \in V$, the period function $T(z_0)$ is well-defined.*

Proof. Fix γ such that $\gamma' = \mu$ and $\gamma(\bar{\mu}) = 0$. Then, γ is strictly increasing before $\bar{\mu}$ ($\gamma_{\uparrow}$ the restriction) and strictly decreasing after ($\gamma_{\downarrow}$ the restriction). In particular, taking V smaller if necessary, we can assume that for any $z_0 < \bar{\mu}$ such that $(z_0, 0) \in V$, there exists $h(z_0) > \bar{\mu}$ such that $\gamma(z_0) = \gamma(h(z_0))$. The function h is actually defined by the formula $h(z_0) = \gamma_{\downarrow}^{-1}(\gamma(z_0))$ and is $\mathcal{C}^1$. As noticed before, along the flow the map $(y_1, y_2) \mapsto y_2^2/2 - \gamma(y_1)$ is constant, in particular starting from $(z_0, 0)$, the value of the hamiltonian remains equal to $H_0 := -\gamma(z_0)$. But the only other point of the real axis (belonging to V) on which the hamiltonian can take the same value is $(h(z_0), 0)$. Since the phase portrait is symmetric w.r.t. to the real axis, the period function is given by $T(z_0) := 2 \min\{t > 0 : \gamma(y_1(t)) = -H_0\}$. On the interval $(0, T(z_0)/2)$ the map $t \mapsto y_1(t)$ is strictly increasing so that we infer (using $s = y_1(t)$)

$$\frac{T(z_0)}{2} = \int_0^{\frac{T(z_0)}{2}} dt = \int_{y_1(0)}^{y_1(\frac{T(z_0)}{2})} \frac{ds}{y_1'(y_1^{-1}(s))} = \int_{z_0}^{h(z_0)} \frac{ds}{y_2(y_1^{-1}(s))}.$$

Using the constraint $y_2(t)^2/2 - \gamma(y_1(t)) = H_0$, we get here

$$\frac{T(z_0)}{2} = \frac{1}{\sqrt{2}} \int_{z_0}^{h(z_0)} \frac{ds}{\sqrt{H_0 + \gamma(s)}}.$$

B The entropy

We explain why two specific idendities are singled out in section 2.4. We set

$$\alpha = \frac{d_1 + d_2}{|d_2 - d_1|} - 1 \tag{42}$$

and define

$$I(t) = \int_{\Omega} \left(G(u_{\varepsilon})(x, t) + \frac{1}{2} v_{\varepsilon}^2(x, t) + \alpha \frac{w_{\varepsilon}^2}{2} \right) dx,$$

$$J(t) = \frac{1}{\varepsilon} \int_{\Omega} (v_{\varepsilon} - F(u_{\varepsilon}))^2 dx.$$

We compute, combining the idendities (32) and (33)

$$\begin{aligned} \frac{dI(t)}{dt} + J(t) &= -d_1 \int_{\Omega} F'(u_{\varepsilon}) |\nabla u_{\varepsilon}|^2 dx - d_2 \int_{\Omega} |\nabla v_{\varepsilon}|^2 dx - \alpha \int_{\Omega} \nabla w_{\varepsilon} \cdot (d_1 \nabla u_{\varepsilon} + d_2 \nabla v_{\varepsilon}) dx \\ &= -d_1 \int_{\Omega} [F'(u_{\varepsilon}) + \beta] |\nabla u_{\varepsilon}|^2 dx \\ &\quad - \int_{\Omega} [d_2(1 + \alpha) |\nabla v_{\varepsilon}|^2 + \alpha(d_1 + d_2) \nabla u_{\varepsilon} \cdot \nabla v_{\varepsilon} + d_1(\alpha - \beta) |\nabla u_{\varepsilon}|^2] dx \end{aligned}$$

Depending on our choice of α , we find β such that the last expression is a square, that is

$$\begin{aligned} \alpha^2(d_1 + d_2)^2 &= 4d_2(1 + \alpha)d_1(\alpha - \beta), \\ -\alpha^2(d_1 - d_2)^2 + 4d_1d_2\alpha &= 4d_1d_2(\alpha + 1)\beta. \end{aligned}$$

And thus the largest value of β is given by

$$4d_1d_2\beta = \max_{\alpha>0} \frac{-\alpha^2(d_1 - d_2)^2 + 4d_1d_2\alpha}{\alpha + 1}$$

the first order condition gives

$$\begin{aligned} \alpha^2(d_1 - d_2)^2 + 2\alpha(d_1 - d_2)^2 - 4d_1d_2 &= 0, \\ (d_1 - d_2)^2(\alpha + 1)^2 &= (d_1 - d_2)^2 + 4d_1d_2 = (d_1 + d_2)^2 \end{aligned}$$

and the positive root is the value in (42).

- For $d_2 > d_1$, we find

$$\alpha = \frac{2d_1}{d_2 - d_1}, \quad \beta = \frac{d_1}{d_2},$$

because $4d_1d_2\beta = \frac{2\alpha(d_1-d_2)^2-4d_1d_2+4d_1d_2\alpha}{\alpha+1} = \frac{2\alpha(d_1^2+d_2^2)-4d_1d_2}{\alpha+1} = \frac{1}{d_1+d_2}[4d_1(d_2^2+d_1^2) - 4d_1d_2(d_2-d_1)]$.

- For $d_1 > d_2$, we find

$$\alpha = \frac{2d_2}{d_1 - d_2}, \quad \beta = \frac{d_2}{d_1},$$
