Towards a Greener Pharmacy by More Eco Design

Michel Baron

Abstract This review proposes an overview of the main trends explored by the pharmaceutical industry in order to develop a greener and smarter pharmacy minimizing any negative impact to the environment, and using more sustainable processes and drugs. If many drugs have their origin in nature, many active ingredients are “toxic by design”. Some trials were carried out to design “green pills”, or greener active ingredients “benign by design”, avoiding the environmental pollution risk. More efforts were developed to reduce fine chemicals production footprints, and to decrease their E factor. Biotechnology, and the use of enzymes for some transformation reactions is another good way of progress. Advanced galenics allows to reduce drug footprints on environment, since it can deliver the right dose of drug at the right time and at the right place, decrease the drug doses, and lower the wastes. Use of continuous processes is a strong trend in the area of primary and secondary pharmaceutical production. It is linked to the quality by design concept and to the in process control by process analytical technology tools. Added to their diversification strategy, and despite their lower research productivity, and that more and more patented blockbusters become or will become generics soon, it will help the pharmaceutical companies to continue their development. At the same time, these efforts toward a greener pharmacy, and a social education of patients, will contribute to the health organization economies and to preserve the future of our planet.

Keywords Green pharmacy · Benign by design · Advanced galenics · Green manufacturing · Solvent free synthesis · Continuous process

Introduction

The traditional model of pharmaceutical industry has changed a great deal since many factors decreased its profitability: the research productivity lowers, the requirements of health authorities in terms of patient safety are strengthened, the drugs refundings decreases, the blockbusters patents get in the public domain... As a result, the pharmaceutical industry is searching for new growth drivers. The big pharma companies developed a diversification strategy for 10 years, and the return on investment begins to appear, thanks to the fast growing emerging markets as well. Two main tendencies emerge from this: The development of generics, drugs already in the public domain, with very active international actors (but in this case, the price of drugs is rather low, and cost effective processes are needed for their production), and the development of bio drugs, more adapted to each patient (but in this case, the developing cost is very high, with an uncertain return on investment). One important new trend consists in developing a smarter green pharmacy fitting with mankind ambitions on the planet. This must be a global approach, including more eco design for pharmaceutical products and processes.

The Green Pill Paradigm

If many pharmaceutical drugs come originally from nature, these drugs and their derivatives designed to improve their

e mail: michel.baron@mines albi.fr

therapeutic action are “toxic by design”, and their toxicity depends on the dose used. If they are not destroyed in the metabolism, after emission in the waste water, some remain for a quite long time in the environment. One possibility to avoid this situation is to imagine drugs “benign by design”, with a similar therapeutic activity, but a better degradability in the environment.

Drugs from Green Sources

Many drugs have their origin in nature, and many plants were the basis of traditional medicine for thousands of years, all over the world, in Africa, America, Oceania, India, Asia, Europe [1]. Some examples of products extracted from plants are for instance cardiotonic heterosids like digitalin, coming from the plant *digitalis purpurea*, or alkaloids as morphine coming from *papaver somniferum* (Fig. 1) [2].

The chemists often use a natural molecule as a model to create a therapeutic class using semi synthesis. This sometimes gives more active products, and many alkaloid derivatives have been found active as antitumor compounds. Some examples are Taxotere, Vinorelbine, or Taxol (Fig. 2) [3].

Bacteria also provides sources of natural products, as for instance antibiotics. When Fleming discovered the antibacterial action of penicillium's cultures [4], he has already imagined that penicillin was a chemical compound with a

Fig. 1 *Papaver somniferum* and morphine 1

Fig. 2 Semi synthetic antimitotic agents: Taxol (a), Taxotère (b) and Vinorelbine (c) (after Potier [3])

Fig. 3 Penicillin G (a) and V (b)

definite structure. The antibacterial action was actually due to the structure of penicillin G (Fig. 3). This molecule is very interesting and has been widely used for many years. But its major drawback is its sensitivity to acid conditions in stomach, and it cannot be taken orally. Another molecule was developed on account of this, penicillin V (Fig. 3) showing a very similar structure and which can be taken orally, since its β lactam ring is stronger for sterical reasons. This was a great progress and penicillin V is still widely used for pediatric and other applications. From that time, many antibiotics were developed in various series (cephalosporins, etc.). Biological resources of the oceans have been exploited as well since human history, by catching fish and harvesting algae, and research during last decades on marine animals and algae revealed the importance of these resources to produce various molecules as antitumor agents, for the treatment of human diseases [5].

Toxic by Design

Many natural products display high toxicity, as snake venoms, or natural alkaloids (strychnine,...) synthesized in cells secondary metabolism. Some molecules coming from the nature or their derivatives obtained by semi synthesis are often very active as drugs, and naturally “toxic by design”, depending on the dose, and as edicted in Latin by Paracelsus: “dosis sola facit venenum”, meaning “only the (inappropriatly high) dose determines that a drug is a poison” [6]. This is the basis of the therapeutic index concept, giving the ratio between the active dose and the toxic dose for a drug.

Semi synthesis is often used to improve drugs action, as in the case of many semi synthetic antibiotics like penicillin V (Fig. 3), or to create more active artificial drugs

Fig. 4 Naproxen (a), its metabolite 6 O desmethylnaproxen (b), and some of their possible glycuronoderivatives (c g) (after Vree [8])

(as in the case of antitumoral vinorelbine, Fig. 2). Unfortunately, increasing drug activity can decrease its biodegradability, not only inside the body, but also outside.

Drug Metabolism in the Body

After administration to the patient in a specific dosage form, the drug molecules are absorbed into the circulatory system, and can undergo a broad range of reactions during metabolism. If some drugs can be excreted unchanged by the kidneys, as the antibiotics benzylpenicillin or vancomycin, most of them are metabolized by enzymes to different compounds. Drugs are generally hydrophobic, and their transformations lead to more hydrophilic products, easier to eliminate in urine or bile. Drug metabolism occurring mainly in the liver [7], is divided into two phases:

- Phase I: the functionalization reactions, introducing or unmasking a functional group (including oxidation, hydrolysis, reduction, hydration...). It involves Cytochrome P 450, a family of enzymes catalyzing various reactions as hydroxylation or epoxidation of different substrates.
- Phase II: the conjugation reactions, leading to highly polar inactive or less active molecules ready to be

excreted. The conjugation can be a glycuronidation, a sulfation, acetylation...

In general, the metabolism of a drug decreases its therapeutic effect. This is important, to avoid that after reaching the site of action, the drug produces its effect longer than to be desired or becomes toxic.

An example of metabolism is given in the case of the antiinflammatory drug naproxen (Fig. 4): the original drug is oxidized in humans to 6 O desmethylnaproxen (phase I) and both parent drug and metabolite are conjugated (phase II) as acylglycuronides [8].

The Flow of Drugs to the Environment

After its flow through the body, half the drug is sometimes rejected without change, and remains days, months or years in the water (Fig. 5) [9]. Fortunately, pharmaceutical products (active ingredients and metabolites) concentration in the environment is very low, and very far from the therapeutic dose. These substances are not eliminated from the water by usual methods, and a small quantity can be detected even in drinking water. According to the research in this field which began about 15 years ago, the risk of adverse effects through the ingestion of pharmaceuticals

Fig. 5 The flow of drugs to the environment (adapted from [9])

present in the drinking water seems to be negligible [10]. But some researchers are now wondering whether low doses of drugs mixtures could have some consequences for human health. In the case of “chemical mixtures” [11] synergy can exist with other emerging organic contaminants (EOC) and endocrine disruptive compounds (EDC), including oestrogens or bisphenol A (BPA) [12, 13]. These molecules and other coming from phytosanitary products (insecticides, herbicides,...), paints, solvents..., as DDT, PCB or flame retardants are widely spread in the nature, and due to their lipophilic character, they can concentrate in the food chain, with a potential risk for human, but this is still not well established and remains to be investigated [14]. Some smart processes were developed to destroy these compounds in a solid state and are now well established [15, 16]. The treatment [17] and valorization of sediments is also possible [18]. The possibilities of environmental remediation by genetically engineered bacteria was also explored [19].

Anyhow, the diffusion of these molecules in the aqueous environment makes more difficult the waste treatment. Biodegradation of phytosanitary products in biological wastewater treatment was tested successfully [20].

In the case of pharmaceutical molecules, advanced effluent treatment is not sustainable because of energy consumption, efficiency and efficacy, and its appropriateness must be assessed at a case by case study [21]. It can apply in the case of the pharmaceutical factories industrial effluents, since the wastes are well characterized in terms of quantity and quality. Till now, little is known about the fate of pharmaceutical molecules during sewage treatment

[22], depending on the operating conditions (aerobic, anaerobic,...) as well as in the environment. For instance, a UV disinfection can create new products sometimes more toxic than the initial molecule [22]. Photoproducts can even be formed by natural sunlight. Microbial transformations can also create more toxic metabolites, as for instance in the case of BPA, methylated by *mycobacterium* species to mono and dimethyl derivatives showing increased toxicity on zebrafish embryo exposed to these molecules [23]. Further environmental research is needed to understand better the transformations of drugs, and other molecules, and to imagine the best methodology in order to decrease or eliminate the undesirable metabolites.

Is the Green Pill an Utopia?

As the flow of drugs and metabolites to the environment (Fig. 5) can pollute the environment, some trials were carried out to transform pharmaceutical active ingredients into molecules having the same activity with human patient, but breaking down easily under the natural environmental conditions, as glufosfamide, obtained by the modification of a known leading structure [24].

Glufosfamide (Fig. 6) is a glycoconjugate obtained by associating glucose with ifosfamide [25, 26]. The rationale is because the cancer cells have an increased affinity to glucose called “the Warburg effect”. Glufosfamide has proven cytotoxic effects in preclinical and clinical trials, with many tumors. At the same time, its biodegradability is enhanced. It was proven that the biodegradability of this kind of compound depends on the stereochemistry of the glucoconjugate [27].

The computer aided design of new active molecules, in terms of discovery and development, showed its interest, to develop new drugs for various diseases, in particular for cancer therapies [28]. The use of this high technology could be a new way to develop drugs “benign by design”, and better biodegradable pharmaceuticals. Anyhow, if this is an excellent target and model to follow, it will require many years to make all drug substances “benign by design”, and the in silico screening for an early selection of drug candidates with favourable properties with regard to degradation is considered as still in its infancy [29].

Fig. 6 Ifofosfamide (a) and Glufosfamide (b)

Greener Drugs by Advanced Galenic?

Galenics is a very traditional science and art, and is considered in Europe as an invention by Galen [30], who developed the first galenic form, a pill made of a mixture of gum and a drug. Nowadays, many dosage forms have been developed, considered as traditional dosage forms, such as a tablet, the most popular and used dosage form in pharmacy because of its low cost and handiness for patients. Galenics shifted in the past decade from an empiric formulation to an engineered approach of pharmaceutical technology. New galenics aims to deliver the right dose of active ingredient at the right time and the right place. It means to use advanced pharmaceutical technology, and to invent and to develop adapted intelligent Drug Delivery Systems. It can be noted that a pharmaceutical dosage form contains not only active ingredients, but also excipients. Many of them come from natural sources, as cellulose, starch, gelatin, lactose, ..., and are widely used after transformation and/or purification. One tendency is to develop more and more excipients coming from natural sources (pectin, trehalose, chitosan,...), due to their better sustainability. It will not be developed in this review, and the readers interested in this area are invited to consult the extensive literature dedicated to it [31–35]. The development of advanced galenics, including the use of futuristic high technology nanodrugs [36] is now exponential. For this reason, it is inconceivable to present an exhaustive panorama. Some emblematic examples of developments contributing to green drug are described hereafter.

One way of progress is to improve drug bioavailability by advanced galenics, decreasing the footprints of dosage forms and drugs in the environment. Many examples of improvements appeared in the literature, as for instance the enhancement of bioavailability of poorly water soluble drugs, typically Class II drugs of the biopharmaceutics classification system (BCS, [37]) showing high lipophilicity and high lattice energy [38] by the use of various technologies. One important challenge is to develop particle engineering for drug delivery, in order to integrate these particles in dosage forms. Particle engineering for pulmonary delivery has drawn much attention. For this purpose, the properties of particles [39] in terms of size distribution, shape, morphology, flowability, surface energy, stability... must be well adapted to this application route.

Particle engineering strategies traditionally include top down and bottom up methodologies

Among the top down methodologies, one can notice the micronization [40] for instance using a jet milling. It allows to produce very fine particles and it has the advantage of being an industrial method. One drawback is

that the granulometric particle size distribution is sometimes broad, and it is rather difficult to control the shape, morphology, surface properties and electrostatic charge of the particles, since the newly created surfaces are thermodynamically activated, which create some instabilities. Another risk is to decrease the crystallinity and enhance the surface and chemical degradation, and to decrease the flowability. Some processes were developed as for instance the co-micronization of fenofibrate with various adjuvants as lactose monohydrate or microcrystalline cellulose, to improve the dissolution speed [41]. Drug micronization can be obtained by spray drying of a drug solution. But in this case, the particles are thermodynamically activated. The obtained amorphous particles show a tendency to recrystallize, thus changing the dissolution speed and then the future bioavailability of these particles. Spray Freeze drying using liquid nitrogen was used to prepare hollow porous microparticles of heat sensitive drugs [39].

Beside drug micronization, nanomization [42] by dry or wet process was carried out for solid active ingredients. When the size of particles decreases, the dissolution kinetics increases, and this allows to decrease the dose of active ingredients [43]. The use of supercritical solvents for fine particles design increased recently [44], and Bettini et al. reported that if some processes have been already scaled up to industrial manufacturing, the potential of this technology still remains largely unexplored. An inhalable insulin was developed, but an increased incidence of lung cancer among previous smokers was noticed after inhalable insulin treatment. Furthermore the treatment cost was much higher than the traditional form. Nevertheless it was found recently that inhalable insulin could present the advantage of attenuating pulmonary inflammation [45].

Bottom up strategies show some advantages, as for instance lower energy use than grinding, but on the other hand they call for solvent use. Among them, we can quote the microcrystallization of drugs. It has been developed to overcome milling induced disorders of crystalline powders. Another method was developed to stabilize inhalable proteins, to provide flowability, dispersibility and biochemical and conformational stability of the proteins, using supercritical fluid technology [39].

If the use of spherical crystallization [46] and the quasi emulsion solvent diffusion (QESD, Fig. 7) method has been well known to improve the properties of active ingredients [47], an antisolvent process involving ionic liquids was used recently to prepare ultrafine rifampicin particles [48].

Tools for Advanced Galenics

Many tools can be used to develop dosage forms, combining top down and bottom up technologies:

Fig. 7 Spherical crystallization by QESD method [47]

- amorphization of active ingredients by various methods among them the solvent method, the milling technology or the hot melt method [49]. The amorph form of drug is often more soluble than crystalline one. This way can be used to decrease the drug dose. The risk is to generate a crystallization inside the dosage form, and to loose a part of the drug activity during conservation. Some researchers proposed to stabilize amorph forms inside polymers for instance [50], and/or to produce solid dispersions [51, 52].
- use of a drug's more soluble polymorphic variety. In this case, the risk would be to create another crystalline form during the process or during conservation. Drug nanocrystals of indomethacine in the metastable form were produced using hydrophilic adjuvants as stabilizers [53].
- salts formation; the salts of active ingredients are generally much more soluble in water than the basic or the acidic form.
- co crystallization was developed rather recently and is a good tool as well to improve the bioavailability of drugs [54].
- encapsulation inside cyclodextrins: Hydrophobic drugs with low solubility can be encapsulated into hydrophilic cyclodextrins, and then their apparent solubility increases during the time necessary for sufficient absorption (2-6 h) in the gastrointestinal tractus. Then the active ingredient can pass the gastro intestinal barrier and the drug is transferred to the blood (Fig. 8). This encapsulation allows to decrease the active ingredient dose in a drug, and its daily dose, as observed also in the case of liposome encapsulation [55]. Various processes were proposed for cyclodextrin encapsulation including comelting [56], kneading [57, 58], or use of supercritical CO₂ [59]. This last possibility is very efficient, but expensive at the industrial scale.

Many combinations were developed from the above mentioned technologies, as to combine the use of cyclodextrins and nanoparticles [60], or to combine co crystallization and extrusion [61].

Fig. 8 Drug absorption after cyclodextrin encapsulation (adapted from [59])

Advanced Drug Delivery Systems (DDS)

If the first DDS were developed in order to increase the concentration of drug in the blood, the new DDS aim to maintain locally in the body precise drug concentrations. Another development is to use drug delivery technology for tissue engineering and regenerative medicine [62]. Many intelligent drug delivery systems were developed including photoresponsive polymersomes [63] (vesicles desintegrating upon U.V. irradiation), two layered dissolving microneedles for percutaneous delivery of peptides/protein [64], etc. Some efforts were carried out to develop sustainable release [65, 66].

The development of advanced galenics is now exponential. This is a good news for the patients. One limitation will be the cost of these technologies. Another is the safety of drug use.

Less Footprints for Fine Chemicals and Biotech Active Pharmaceutical Ingredients (API)

Concerning pharmaceutical fine chemicals and biotech active ingredient, increasing handling and use measures at the source is necessary in the long run. Due to the specificity, complexity, multistep character and purity targeted on these syntheses, the primary pharmaceutical production of API is considered as having one of the worst E factor

among the chemical industry sector (25–100 kg or more of waste by kg of API produced) [67]. If the bio industries involved in the production of drugs need very small amount of solvent, they need a deal of water for production and cleaning [68]. The big pharmaceutical companies worked a lot on their processes, to simplify and make them greener. Process R & D must design the best synthetic routes for active ingredients.

Small Molecules Syntheses

To synthesize small molecules as API, the companies search how to decrease the energy and time used for unitary operations, the amount of solvent... Some use microwaves to warm up the polar entities [69] for the scale up of organic reactions in a pharmaceutical Kilo lab. Other use ultrasonic conditions, since ultrasonic irradiation enhances chemical reactions and mass transfers via acoustic cavitation [70, 71] and many work on the processes intensification, as reported by Buchholtz [72], introducing more continuous chemical reactions. As edicted by Sheldon [73] “the best solvent is no solvent”, and some possibilities were proposed in order to use solvent free syntheses in high energy vibrating ball mills [74, 75] (Fig. 9). Due to the co grinding stochastic character, the kinetics is sometimes slow. Nevertheless, this method is interesting, because the absence of solvent makes often the synthesis globally safer, faster, energy and cost efficient. Due to high API complexity, and stereoisomeric needs, catalytic methodologies are often chosen, but as noticed by Federsel from Astra Zeneca [76], many catalysts used today contain a heavy metal component, and this can induce a contamination of the product and of the wastes as well. For this reason, a catalytic process is rarely green, and many companies are in search of green catalysts [77].

Enzymatic Methodologies

Use of enzymatic methodologies is an interesting way, since an enzyme can be considered as a natural catalyst, and the specificity of enzymes can be enhanced by

Fig. 9 Dibenzophenazines (a, b) and dibenzopyrido quinoxaline (c) solvent free synthesis [74, 75, 77]

Fig. 10 Atorvastatin 10

mutations of the protein chains. Some companies developed the use of enzymes instead of microorganisms, as DSM to produce semi synthetic penicillins, decreasing drastically the use of solvents for the purification steps, and purer antibiotics were obtained by this way [78]. They reduced energy consumption by 66 %, and wastes by 90 % compared to the traditional process. Another example is the synthesis of atorvastatin (10, Fig. 10), the active ingredient of Lipitor invented by Pfizer to treat hypercholesterolemia, one of the most sold drug in the world. The chemical synthesis of atorvastatin, uses traditionally cyanide and stoichiometric sodium borohydride (at -70°C) to produce 200T/year of the key chiral building block ethyl (*R*) 4-cyano 3-hydroxybutyrate (Hydroxynitrile 11, Fig. 11). But the obtention of this intermediate needs a separation of the racemic to isolate the good isomer. Codexis developed a new “green by design” biocatalytic process using Halo hydrin deshalogenase customized enzyme (Fig. 11) [79]. Table 1 [80] shows the advantages of the bio synthesis in terms of energy, yield, concentration... This biosynthesis was developed at a multi tons scale.

Similarly, Merck and Codexis improved drastically sitagliptin (antihyperglycemic drug used against diabetes) synthesis, using a customized enzyme [81].

In a general point of view, big pharma think green and to search new alternatives for primary production processes. Two main ways of progress are developed: synthesis of small molecules by direct routes, using less solvents, and if possible water or no solvent. When the complexity is increased, or in case of stereospecificity, use

Fig. 11 Synthesis of Atorvastatin key intermediate Hydroxynitrile 11 (adapted from [79])

Table 1 Comparison of the biocatalytic and chemical processes for the production of Hydroxynitrile [80]

Parameter	Enzymatic process	Chemical process
Crude substrate load	0.3 kg/L	0.1 kg/L
Substrate/catalyst (wt/wt)	Approximately 100:1	1:1
Conversion (%)	99.3	Not provided
Diastereomeric excess (%)	99.99	94
Cryogenic reaction conditions required	No	Yes
Solvent use	3.2 L/kg	27.5 L/kg

of catalysts or biotech ways are explored as well. In this case, isolation and recycling steps must be important key points of the process.

Pharmaceutical Forms Greener Manufacturing

Beginning of 2000, the Food & Drug Administration (FDA) inspectors noticed that the actual yields in the drug formulation (secondary production) facilities were lower than expectation in the marketing authorization applications, and that the production time was often much longer. Furthermore, they noticed that a lot of products which were not matching the quality standards had to be destroyed. The result was the implementation of quality by design (QbD) for pharmaceutical products research, development and production. This concept is linked to the process analytical technology (PAT) one, allowing the continuous monitoring of pharmaceutical processes, in order to ensure products final quality [82]. PAT is very well adapted to continuous processes and it is developing progressively in the industry,

Fig. 12 Symbolic pharmaceutical continuous process (after [84])

with various applications [83]. Novartis and the MIT develop a joint program “Blue sky vision” to transform batch oriented pharma production to a fully continuous approach [84] integrating QbD, and starting from chemical synthesis through final pharmaceutical dosage form (Fig. 12), promising impressive advantages in terms of total capital and operating costs.

If the idea of producing tablets by continuous process was launched some years ago [85], GSK, GEA and Siemens developed a new system for tablet continuous manufacturing [86]. Concerning the specific continuous drying and tableting process, the savings aimed is 65 % lower building volume, 60 % lower capital cost, 85 % less waste, 60 % less manpower, and less solvent. Some research groups in the world work on the questions raised by continuous blending of powder mixtures with pharmaceutical constraints [87].

If the development of continuous processes needs research and development investments, and investments in new machines at the beginning, it can generate profits in the long term, by increasing the yields of pharmaceutical forms, and helping to make the processes greener than before, then generating other advantages to the company. Recently, Pfizer developed the co design by modeling between R & D and manufacturing [88], allowing the members of the team to examine each step of possible route, for commercial nomination. Use of continuous processes is generally a good way to cut costs, and the technology is emerging in the pharmaceutical industry manufacturing [89]. At the same time, at the research level, new cost effective green processes are explored, which can be implemented in future more or less continuous manufacturing processes. These can be for instance direct compression [90], fast melt granulation [91], extrusion/spheronization in the presence of water as solvent with various grid geometries [92, 93] (Fig. 13), coating processes using water instead of organic solvents [83], dry coating [94–97] or other green processes.

Fig. 13 Pharmaceutical extrusion using a dome geometry grid [92, 93]

Good Use Practices

In order to preserve a safe environment, it seems obvious that our societies must evolve in the direction of diminishing drugs dissemination in the environment. A similar way is aimed for agriculture (intrants and phytosanitary products), and of course in a general point of view in the use of all kind of chemical products.

For the pharmaceutical drugs, a safe dispensation of the exact dose of drug needed by the patient in the case of prescriptions must be organized. In the case of self medication as well, the behaviour of the patient is important, avoiding overmedication. When drugs remain in the medicine chest, and of course when the expiration date is over, the patients must go to retail pharmacies, to give back the remaining drugs. A system exists in many european countries to recover and destroy them by incineration. Since the recycling by humanitarian associations is not longer in use (mainly due to quality defects), this system is the best to avoid the dissemination of drugs in the nature. The FDA recommends a few medicines to be flushed down the sink or toilet to help prevent danger to people and pets in the home [98]. This is only in some cases as aspirin, very rapidly destroyed in water and destroyed at 99.9 % in water treatment plants. But this choice is difficult for the people not well informed of the complexities and varieties of drug molecules. Some researchers published recently a life cycle comparison of environmental emissions from three disposal options for unused pharmaceuticals [99], and recommended as a result the trash disposal of unused pharmaceuticals. But it is without taking into consideration the fact that after a while, the molecules can diffuse and pollute the environment. Then the incineration with energy

recovery is at the present time the best way to destroy the medicines and their packaging, excepted in the case of drugs or organic products needing a special treatment [15, 16]. It is of course regrettable not to recycle the drug and provide them to affected populations, but the good solution for this was not found until now, despite some interesting proposals to improve the liability [100].

For this, the recovery of unused drugs by patients, a social education is necessary for the proper disposal of unused and expired medications in all countries [9].

A particular attention should be paid to hospitals and care institutions, to avoid toxic effluent discharge, due to relative high concentration of drugs in the effluents. We also must consider the fact that a reprocessing of drugs is possible in the industrial processes, if it has been anticipated in the marketing authorization [101]. Following recovery of the active ingredient and recrystallization, a new expiry date can be attributed, to avoid a waste of drug.

If the focus was made on the drugs in this paper, more generally, many other molecules (PCB, phthalates, bisphenol A, herbicides, and traces of more simple molecules as flame retardants, glycol ethers...), could have an impact on environment. Then, even if some adapted methods have been developed to eliminate these molecules from the environment [15], the best choice is to decrease the doses applied, and to avoid the dissemination of the leftover products in the environment.

The notion of Ecopharmacovigilance is developing, to evaluate and to control the risk of dissemination of pharmaceutical drugs in the environment, and decrease the emission level. This should be applied to all kinds of molecules potentially harmful for the environment, alone or in mixtures.

Conclusions

For the last decade the pharmaceutical industry moved towards making greener products and processes. This goal will be attained by using more eco design in active ingredients and drugs conception, as well as the processes at all stages of R & D and production. Among the various possibilities, it is possible to quote:

- development of processes using only water, or solvent free processes
- use of catalysts, and if possible green catalysts
- development of continuous processes
- development and implementation of PAT for in process control and to increase pharmaceutical operations yield
- development of an advanced galenic, including DDS, to ensure drug delivery of the right dose, at the right time, and at the right place.

- lean and project management at all steps of development and production

Research in new emerging processes requires multi disciplinary teams to work together, and of course some investments in R & D. The cost of these technologies must be well considered but they will help to match the objective of sustainability. And there is no longer doubt that the return to investment will be efficient, for the companies and their development as well as the health economy, and for our planet environment. If the pharmaceutical drugs “benign by design” could be an interesting target for the future, the processes generated by eco design for primary and secondary processing must be both ecologically and economically efficient, to save costs and create the future of pharmaceutical companies, of health organizations systems, and of our planet. A social education will contribute to avoid the dissemination of potential harmful products in the environment, and to recover unused drugs by the patients.

Acknowledgments Some case studies cited in this article were made by former and present coworkers and Ph'D students in our research center RAPSODEE (Ecole des Mines d'Albi CNRS Université de Toulouse France) and/or Spin Center (Ecole des Mines de St Etienne, France) and/or Paris South XI University France, whose names appear only in the reference list. The author expresses his sincere appreciation for their tremendous efforts invested in their research works. Financial supports are also appreciated, among others those from the Ministry of Economy, Finances and Industry, from the Centre National de la Recherche Scientifique (CNRS) and from the Agence Nationale pour la Recherche (ANR).
