Abstract

We describe the mitochondrial genome of *Hydropsyche pellucidula* Curtis 1834, which is the first described for the suborder Annulipalpia and the first in the order Trichoptera to show a non-canonical gene order. The mitogenome was obtained by *de novo* assembly of shotgun sequenced total genomic DNA using Illumina Miseq technology, which produced an average coverage of 115x and a minimum coverage of 48x. The mitochondrial genome includes 13 protein-coding genes, 2 rRNAs, 22 tRNAs. The genome is characterized by a rearrangement in the relative position of protein-coding and ribosomal genes. This mitogenome sequence will be useful for studies of the family Hydropsychidae, which is commonly used for freshwater pollution biomonitoring.

Keywords

Mitochondrial rearrangement, mitochondrial metagenomics, Hydropsychoidea, biomonitoring

Main text

The insect order Trichoptera contains around 12,000 described species (Mackay & Wiggins 1979). Both the aquatic larvae and terrestrial adult stages are essential components of aquatic and riparian communities and are used for biological assessment of water quality (Mackay & Wiggins, 2003; de Moor & Ivanov, 2008). We sequenced the mitogenome of *Hydropsyche pellucidula BMNH-1425186* (Trichoptera: Hydropsychidae). The high bioindicator value of the genus *Hydropsyche* (Tszydel et al. 2015), makes this mitogenome a useful tool for biomonitoring approaches.

The voucher specimen was a larva manually collected from Adam’s Pond, Richmond Park, London, UK. It was morphologically identified and deposited in the Natural History Museum of London (voucher code BMNH 1425186). The mitogenome was *de novo* assembled from a metagenomic library containing other aquatic macroinvertebrates following the mitochondrial metagenomics (MMG) approach (Gillett et al. 2014; Tang et al. 2014; Crampton-Platt et al. 2015). The mitochondrial
contig of *Hydropsyche pellucidula* was identified through its cox1 gene (barcode region) obtained by Sanger sequencing and by its 99.6% similarity to another barcode from Múrria et al., 2010 (HM134820). Gene annotations were predicted using MITOS (Bernt et al. 2013) and were manually refined.

The resulting mitogenome is 25,004 bp long with an even read coverage of 115x on average (min: 48x; max: 280x). We identified 13 protein-coding genes, 2 rRNAs and 22 tRNAs and a particularly long control region (~8kb). A terminal AT rich region did not allow us to circularize the genome with confidence. The gene order differs from canonical insect mitochondria. The *rrnS*, generally located between the *rrnL* and the control region is displaced to a region between *cob* and *nad1* and is flanked by two regions of around 600 and 800bp for which homology could not be established. Additionally, two tRNAs (*trnP, trnI*) are also found in non-canonical positions.

The sequence was validated by the construction of a phylogenetic tree for the order *Trichoptera* based on protein coding and rRNA genes from all complete or nearly complete mitogenomes and transcriptomes retrieved from GeneBank (September 2015; Benson et al., 2014). The dataset included 9 different species sharing a set of mitochondrial loci (*atp6, cob, cox1, cox2, cox3, nad1, nad3, nad4 and rrnL*). Three Lepidoptera genomes were selected as outgroups. Multiple alignments were built for each locus with MAFFT (Katoh & Standley 2013) and a maximum-likelihood phylogenetic analysis was conducted in RAxML-HPC2 (Stamatakis 2006) on the CIPRES server (Miller et al. 2010). The best tree was selected over 100 alternative runs, using a GTR-cat model and node support was calculated with 10000 bootstrap replicates.

As expected, *Hydropsyche pellucidula* is placed in the suborder Annulipalpia (Figure 1), which is recovered as monophyletic. In contrast, the suborder Integripalpia appears to be paraphyletic and contentious as previously reported (Ivanov 2002; Kjer et al. 2002). The tree is also consistent with the recent phylogenomic analysis of Misof et al., 2014. The rearrangement cannot be assigned to a
specific phylogenetic level, as other Annulipalpia data are based on transcriptomes and unknown
gene order. The mitogenome was deposited in Genbank: KT876876.

Acknowledgments

We would like to thank Alex Aitken, Kevin Hopkins and Peter Foster (Natural History Museum), for
their technical assistance and Núria Bonada and Félix Picazo for her help in morphological
identification. PA, CA collected the specimen. PA performed wet lab work. BL, ACP ran the
bioinformatic analyses. BL wrote the manuscript and APV supervised the project. This work was
founded by the NHM Biodiversity Initiative. PA was supported by a postdoctoral grant from The
Royal Society (Newton International Program, UK).

Declaration of Interest

The authors report no conflicts of interest. The authors alone are responsible for the content and

Ivanov, V.D., 2002. Contribution to the Trichoptera phylogeny: new family tree with consideration of

Figure 1: Phylogeny of the order Trichoptera based on 9 mitochondrial loci ($atp6$, $cob$, $cox1$, $cox2$, $cox3$, $nd1$, $nd3$, $nd4$ and $rrnL$). The new mitogenome is highlighted with a white box. Suborders are delimited by red (Annulipalpia) and blue (Integripalpia) backgrounds. Trichoptera species with a complete mitochondrial genome are marked by an asterisk. All other species are based on transcriptomic data, i.e. their relative gene order remains unknown.
