HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers. L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
1.1 Research framework : Embodied Learning

Our goal is to "teach" a robot to interact autonomously in a face-to-face task with a human. Due to the complexity of the task, standard learning approach like learning by observation and kinesthetic demonstration are not efficient enough notably for social signals (such as gaze or head movements). Our approach, based on the embodied learning paradigm, will teach the robot with his own moves by embodied him [10]. Like a puppeteer, a pilot controls the robot remotely using an immersive teleoperation platform. In order to record an interaction with minimal bias, the platform should become "transparent" and the remote world represented in a "natural" way. Our actual research aims at rendering a coherent representation of the remote space and depth perception.

1.2 State of the Art

What we know about humans:
- Depth perception is based on several factors: Binocular disparity (stereovision), occlusion, parallax, convergence, known semantics of the objects [... [16, 5].
- Stereoscopic vision is useful before 15m (cannot differentiate from monovision after[1]
- Vvergence is useful in the peri-personal space (<2.0m) [14]

Current use of immersive teleoperation
- Search and rescue robot [8]
- Drone navigation [4]
- Immersive telepresence [6, 7, 3]

Gaze controlled methods
- Virtual gaze joystick "Moving to the center" [17][12]
- EyeSeeCam [11, 13]

Limitations of current immersive teleoperation devices
- Underestimation of depth in personal space (<2m), overestimation after 2m [2]

Drawback : In those setups, the stereo rig is fixed. The pilot loses the vvergence information and control, has reduced depth perception and experiences the accommodation-vvergence conflict. For a human facing the robot, the robot gaze is less interpretable.

1.3 SGCS : Stereo Gaze Contingent Steering

Proposed approach : Here we propose a new natural control method for a pair of stereoscopic robotic eyes with vvergence abilities, called SGCS (Stereo Gaze Contingent Steering), running alongside the control of a robotic head. An evaluation of the control method has also been performed.

2.2 Technological platform

We use the Mical platform "NA" from the CRISPS team at Gipsa. Specification :
- Icos 2.0 with enhanced face articulation [9].
- Cluster of 4 PC (3 Linux + 1 Windows) running a yarp (client-server robotic middleware).
- HTC Vive + SMI integration for eye-tracking
- IPD cameras equivalent to human IPD => reduced hyperstereopsis
- Communication with UDP/TCP through the YARP middleware
- IPD cameras equivalent to human IPD => reduced hyperstereopsis
- HTC Vive + SMI integration for eye-tracking
- Cluster of 4 PC (3 Linux + 1 windows) running a yarp (client-server robotic middleware).
- Icub 2.0 with enhanced face articulation [9].

3. Control methods

The control of the head and eye is done through a trangular command for the six head encoders: $\text{[roll, pitch, yaw, left, right, neck]}$.$\text{[roll, pitch, yaw, left, right, neck]}$

1. Head control: The head angles are driven by the HMD orientation value (standard approach).

2. Eye control:
   2.1 Gaze controlled methods
      (a) StereoClock: Using a transfer matrix $(UV_{to\_angle})$, the model is able for a chosen target (defined by a UV pair) to return an absolute angular command value to center the two stereo cameras images on it. This inverse linear model has (surprizingly) a precision of 0.5 on the three angles.
      
      $\text{UV}_{to\_angle} = \begin{bmatrix} u \backslash v \\ x \backslash y \backslash z \end{bmatrix} = \begin{bmatrix} [\text{roll, pitch, yaw, left, right, neck}] \end{bmatrix}$

3. Foveal display: Move the center of the video texture in the virtual world to a coherent position for the robot and cues on the pilot side.

4.4 Results

Discussion: Our SGCS control method is able to move the robotic eye in coherence with the orientation of the human eye (the camera optical axis is aligned with the human gaze). The cameras are looking where the human is looking with respect of tilt, azimut, and vvergence.

Future works: * Hypothesis: Control of vvergence improves perception and evaluation of depth in the near and medium field while maintaining oculomotor cues and reducing the accommodation-vvergence conflict. * Improve the reactivity of the control method: detection of fixation and saccades.
