Design and analysis of a finite volume scheme for a concrete carbonation model

Claire Chainais-Hillairet, Benoît Merlet and Antoine Zurek

Abstract In this paper we introduce a finite volume scheme for a concrete carbonation model proposed by Aiki and Muntean in [1]. It consists in a Euler discretisation in time and a Scharfetter-Gummel discretisation in space. We give here some hints for the proof of the convergence of the scheme and show numerical experiments.

Key words: Finite volume scheme, convergence analysis, free-boundary system

MSC (2010): 65M08, 65N08, 35Q30

1 Introduction

The carbonation phenomenon is a physico-chemical reaction which is the main cause of concrete structure degradation. We can describe the carbonation process as follows: $\text{CO}_2(\text{g})$ from the atmosphere enters in the concrete and it is quickly transformed in $\text{CO}_2(\text{aq})$. The introduction of $\text{CO}_2(\text{aq})$ in concrete drives the carbonation reaction. This reaction facilitates a drop of the pH inside the material and allows the corrosion process to damage the metallic reinforcement bars. It deteriorates the concrete and reduces the durability of the structure.

In order to model this phenomenon Aiki and Muntean proposed in [1] a free-boundary system where the varying space domain represents the carbonated zone. The unknowns u and v represent the mass concentration of CO_2 respectively in water and air and s represents the penetration depth which measures the size of the

antoine.zurek@inria.fr

carbonated zone. The unknowns u and v solve a weakly coupled system of reaction-diffusion equations in the varying domain $(0, s(t))$ and s solves an ordinary differential equation. The concentrations u and v are subjected to Dirichlet boundary conditions at $y = 0$ and Robin/Neumann boundary conditions at $y = s(t)$.

For this system Aiki and Muntean have shown in [1] the existence and the uniqueness of a global solution. They also have shown that the penetration depth follows a $\sqrt{t}$ -law of propagation in [2, 3]. Our aim is to define a finite volume scheme for the concrete carbonation model and to show the convergence of the numerical scheme. In this short paper, we just give sketch of the convergence proof. Full details will be provided in a forthcoming paper [8].

2 Presentation of the model

Let us define the carbonated domain $Q_s(T) = \{(y, t) : 0 < y < s(t), 0 < t < T < +\infty\}$. The system considered by Aiki and Muntean in [1] writes

$$\partial_t u - \partial_y(\kappa_u \partial_y u) = f(u, v) \quad \text{in } Q_s(T), \quad (1a)$$

$$\partial_t v - \partial_y(\kappa_v \partial_y v) = -f(u, v) \quad \text{in } Q_s(T), \quad (1b)$$

$$s'(t) = \psi(u(s(t), t)) \quad \text{for } 0 < t < T, \quad (1c)$$

$$s(0) = s_0, \quad (1d)$$

$$-\kappa_u \partial_y u(s(t), t) - s'(t)u(s(t), t) = \psi(u(s(t), t)) \quad \text{for } 0 < t < T, \quad (1e)$$

$$-\kappa_v \partial_y v(s(t), t) - s'(t)v(s(t), t) = 0 \quad \text{for } 0 < t < T, \quad (1f)$$

$$u(0, t) = g(t), v(0, t) = r(t) \quad \text{for } 0 < t < T, \quad (1g)$$

$$u(y, 0) = u_0(y), v(y, 0) = v_0(y) \quad \text{for } 0 < y < s(0). \quad (1h)$$

Here and hereafter we suppose the following assumptions:

- (A1) $\psi : \mathbb{R} \longrightarrow \mathbb{R}$ drives the carbonation reaction and is defined by $\psi(x) = \alpha x$ with $\alpha > 0$,
- (A2) $f : \mathbb{R}^2 \longrightarrow \mathbb{R}$ measures the availability of $CO_2(\text{aq})$ for the carbonation reaction. It is defined by $f(p, q) = \beta(\gamma q - p)$ where β and γ are two real constants,
- (A3) g and r belong to $W^{1,2}(0, T)$,
- (A4) u_0 and v_0 belong to $L^\infty([0, s_0])$,
- (A5) the diffusive coefficients κ_u and κ_v are two positive constants,
- (A6) $s_0 > 0$,
- (A7) there exist g^* and r^* two positive constants such that $0 \leq g \leq g^*$, $0 \leq r \leq r^*$ on $[0, +\infty)$ and $0 \leq u_0 \leq g^*$, $0 \leq v_0 \leq r^*$ on $[0, s_0]$ with $g^* = \gamma r^*$.

For numerical reasons, it is convenient to rewrite (1) on a fixed space domain. For this, we use the change of variables

$$\begin{aligned} \cup_{0 \leq t \leq T} [0, s(t)] \times \{t\} &\rightarrow [0, 1] \times [0, T] = Q(T), \\ (y, t) &\mapsto \left(x(y, t) = \frac{y}{s(t)}, t\right), \end{aligned}$$

and we associate $u(y, t) = \bar{u}(x(y, t), t)$ and $v(y, t) = \bar{v}(x(y, t), t)$. Then if we drop the bars, we obtain, as in [6]

$$s(t)\partial_t(s(t)u) + \partial_x J_u = s^2(t)f(u, v) \quad \text{in } Q(T), \quad (2a)$$

$$s(t)\partial_t(s(t)v) + \partial_x J_v = -s^2(t)f(u, v) \quad \text{in } Q(T), \quad (2b)$$

$$s'(t) = \psi(u(1, t)) \quad \text{for } 0 < t < T, \quad (2c)$$

$$s(0) = s_0, \quad (2d)$$

$$J_u(1, t) = s(t)\psi(u(1, t)), \quad J_v(1, t) = 0 \quad \text{for } 0 < t < T, \quad (2e)$$

$$u(0, t) = g(t), \quad v(0, t) = r(t) \quad \text{for } 0 < t < T, \quad (2f)$$

$$u(x, 0) = u_0(s_0 x), \quad v(x, 0) = v_0(s_0 x) \quad \text{for } 0 < x < 1, \quad (2g)$$

with $J_w = -\kappa_w \partial_x w - s(t)s'(t)xw$, for $w = u$ or v . We now define the notion of weak solution for (2). For this, we introduce the functional space $H = \{z \in H^1(0, 1) : z(0) = 0\}$ endowed with the $H^1(0, 1)$ norm. Assuming (A1) – (A7), we say that (s, u, v) is a weak solution of (2) if the following conditions are satisfied

$$(S1) \quad (u, v) \in (L^2(0, T; H^1(0, 1)) \cap L^\infty(Q(T)))^2,$$

$$(S2) \quad u - g, v - r \in L^2(0, T; H),$$

$$(S3) \quad s \in W^{1,\infty}(0, T), s(0) = s_0 \text{ and } s'(t) = \psi(u(1, t)) \text{ for almost every } t \in [0, T],$$

$$(S4) \quad \text{for all } \phi \in \mathcal{C}_c^\infty([0, T] \times (0, 1])$$

$$\begin{aligned} & - \int_0^T \int_0^1 u(x, t) s(t) \partial_t(s(t)\phi(x, t)) dx dt - \int_0^1 u_0(s_0 x) s_0^2 \phi(x, 0) dx \\ & + \int_0^T \int_0^1 \kappa_u \partial_x u(x, t) \partial_x \phi(x, t) dx dt + \int_0^T \int_0^1 s(t) s'(t) x u(x, t) \partial_x \phi(x, t) dx dt \\ & + \int_0^T s(t) \psi(u(1, t)) \phi(1, t) dt = \int_0^T \int_0^1 s^2(t) f(u(x, t), v(x, t)) \phi(x, t) dx dt, \end{aligned}$$

$$(S5) \quad \text{for all } \phi \in \mathcal{C}_c^\infty([0, T] \times (0, 1])$$

$$\begin{aligned} & - \int_0^T \int_0^1 v(x, t) s(t) \partial_t(s(t)\phi(x, t)) dx dt - \int_0^1 v_0(s_0 x) s_0^2 \phi(x, 0) dx \\ & + \int_0^T \int_0^1 \kappa_v \partial_x v(x, t) \partial_x \phi(x, t) dx dt + \int_0^T \int_0^1 s(t) s'(t) x v(x, t) \partial_x \phi(x, t) dx dt \\ & = - \int_0^T \int_0^1 s^2(t) f(u(x, t), v(x, t)) \phi(x, t) dx dt. \end{aligned}$$

3 Numerical scheme

Let us first introduce some notation related to the discretisation of $[0, 1]$. A mesh $\mathcal{T}$, consists in a finite sequence of cells $(x_{i-\frac{1}{2}}, x_{i+\frac{1}{2}})$ for $1 \leq i \leq l$, with

$$0 = x_{\frac{1}{2}} < x_{\frac{3}{2}} < \dots < x_{l-\frac{1}{2}} < x_{l+\frac{1}{2}} = 1.$$

We define x_i as the center of the cell $(x_{i-\frac{1}{2}}, x_{i+\frac{1}{2}})$ and $x_0 = x_{\frac{1}{2}}$, $x_{l+1} = x_{l+\frac{1}{2}}$. We set h_i the length of the cell $(x_{i-\frac{1}{2}}, x_{i+\frac{1}{2}})$, $h_{i+\frac{1}{2}}$ the length of the interval $[x_i, x_{i+1}]$ and we define $h = \max\{h_i, 1 \leq i \leq l\}$ the size of the mesh. Finally, we define an integer N_T and a time step Δt such that $N_T \Delta t = T$ and $(t_n)_{0 \leq n \leq N_T}$ with $t_n = n\Delta t$. In the sequel, when we use the notation w , it means that $w = u$ or v . We discretize the initial and Dirichlet conditions. We set,

$$s^0 = s_0, \quad (3)$$

$$w_i^0 = \frac{1}{h_i} \int_{x_{i-\frac{1}{2}}}^{x_{i+\frac{1}{2}}} w_0(s_0 x) dx, \quad \text{for } 1 \leq i \leq l, \quad \text{and } w_{l+1}^0 = w_0(s_0), \quad (4)$$

$$v_0^n = \frac{1}{\Delta t} \int_{t_n}^{t_{n+1}} r(t) dt, \quad u_0^n = \frac{1}{\Delta t} \int_{t_n}^{t_{n+1}} g(t) dt, \quad \text{for } 0 \leq n \leq N_T - 1. \quad (5)$$

Then, for $1 \leq i \leq l$ and $0 \leq n \leq N_T - 1$, the scheme writes

$$s^{n+1} = s^n + \Delta t \psi(u_{l+1}^n), \quad (6)$$

$$s^{n+1} h_i \frac{s^{n+1} v_i^{n+1} - s^n v_i^n}{\Delta t} + \left(G_{v, i+\frac{1}{2}}^{n+1} - G_{v, i-\frac{1}{2}}^{n+1} \right) = -(s^{n+1})^2 h_i \beta(\gamma v_i^{n+1} - u_i^n), \quad (7)$$

$$s^{n+1} h_i \frac{s^{n+1} u_i^{n+1} - s^n u_i^n}{\Delta t} + \left(G_{u, i+\frac{1}{2}}^{n+1} - G_{u, i-\frac{1}{2}}^{n+1} \right) = (s^{n+1})^2 h_i \beta(\gamma v_i^{n+1} - u_i^{n+1}). \quad (8)$$

It remains to define the numerical fluxes $G_{w, i+\frac{1}{2}}^n$. We define $C^{n+1} = s^{n+1}(s^{n+1} - s^n)/\Delta t$ and we use the Scharfetter-Gummel fluxes (see [7, 11]), that is:

$$G_{w, i+\frac{1}{2}}^{n+1} = \kappa_w \frac{B\left(h_{i+\frac{1}{2}} \frac{C^{n+1}}{\kappa_w} x_{i+\frac{1}{2}}\right) w_i^{n+1} - B\left(-h_{i+\frac{1}{2}} \frac{C^{n+1}}{\kappa_w} x_{i+\frac{1}{2}}\right) w_{i+1}^{n+1}}{h_{i+\frac{1}{2}}}. \quad (9)$$

Here B is the Bernoulli function defined by $B(x) = x/(e^x - 1)$ for $x \neq 0$ and $B(0) = 1$. We supplement the numerical scheme with Robin/Neumann boundary conditions at $x = 1$,

$$G_{v, l+\frac{1}{2}}^{n+1} = 0, \quad G_{u, l+\frac{1}{2}}^{n+1} = s^{n+1} \psi(u_{l+1}^{n+1}), \quad \text{for } 0 \leq n \leq N_T - 1. \quad (10)$$

We remark that the equations (6), (7) and (8) are decoupled. Thus, if we know (s^n, u^n, v^n) we can compute s^{n+1} by (6) and then v^{n+1} and u^{n+1} thanks to (7) and (8).

4 Main results

Theorem 1. *The numerical scheme (3)-(10) admits a unique solution. Moreover, for every $n \geq 0$ and $i \in \{0, \dots, l+1\}$, we have*

$$0 \leq v_i^n \leq r^*, \quad 0 \leq u_i^n \leq g^*, \quad 0 \leq \frac{s^{n+1} - s^n}{\Delta t} \leq \alpha g^*, \quad (11)$$

and

$$0 < s^{n+1} \leq s^0 + T \alpha g^*, \quad \text{for } 0 \leq n \leq N_T. \quad (12)$$

Sketch of the proof. We rewrite the scheme (7)-(10) as two independent linear systems. Furthermore, thanks to the boundary condition for v at $x = 1$ and the definition of B , we can eliminate v_{l+1}^{n+1} as $v_{l+1}^{n+1} = \exp\left(-h_{i+\frac{1}{2}} C^{n+1} / \kappa_v\right) v_l^{n+1}$, for $n \geq 0$. Hence, as (7)-(8) are decoupled, we obtain two independent linear systems $\mathbb{M}_v^n v^{n+1} = b_v^n$ and $\mathbb{M}_u^n u^{n+1} = b_u^n$, with, for $n \geq 0$, $\mathbb{M}_v^n \in \mathbb{R}^{l \times l}$ and $\mathbb{M}_u^n \in \mathbb{R}^{(l+1) \times (l+1)}$. Then, following the ideas of [6], we prove that $\mathbb{M}_v^n$ and $\mathbb{M}_u^n$ are M-matrices. As a consequence, we deduce the existence of solutions to (S) and the nonnegativity of u^{n+1} and v^{n+1} . Finally, we show that $M_v^n(v^{n+1} - r^* I_l) \leq 0$ and $M_u^n(u^{n+1} - g^* I_{l+1}) \leq 0$ and we deduce the upper bounds of (11) and (12). $\square$

In order to use discrete functional analysis tools we introduce some functional sets. Let $\mathcal{T}$ a mesh of $[0, 1]$ of size h and Δt a time step. We define the set of piecewise constant functions in space as

$$X_{\mathcal{T}} = \{w_h : [0, 1] \longrightarrow \mathbb{R} : \exists (w_i)_{0 \leq i \leq l+1} \in \mathbb{R}^{l+2} \text{ and} \\ w_h(x) = \sum_{i=1}^l w_i \mathbf{1}_{(x_{i-\frac{1}{2}}, x_{i+\frac{1}{2}})}(x) + w_0 \mathbf{1}_{\{x=0\}}(x) + w_{l+1} \mathbf{1}_{\{x=1\}}(x)\}.$$

We define also the set of piecewise constant functions in space and time as

$$X_{\mathcal{T}, \Delta t} = \{w_{h, \Delta t} : [0, 1] \times [0, T] \longrightarrow \mathbb{R} : \exists (w_h^{k+1})_{0 \leq k \leq N_T-1} \in (X_{\mathcal{T}})^{N_T} \\ \text{and } w_{h, \Delta t}(x, t) = \sum_{k=0}^{N_T-1} w_h^{k+1}(x) \mathbf{1}_{[t_k, t_{k+1})}(t)\}.$$

Finally, we define a discrete derivative operator in space $\partial_{x, \mathcal{T}}$ for all $w_{h, \Delta t} \in X_{\mathcal{T}, \Delta t}$ by

$$\partial_{x, \mathcal{T}} w_{h, \Delta t}(x, t) = \partial_{x, \mathcal{T}}^i w_{h, \Delta t} = \frac{(w_{i+1}^{k+1} - w_i^k)}{h_{i+\frac{1}{2}}} \quad \text{for } (x, t) \in (x_i, x_{i+1}) \times (t_k, t_{k+1}).$$

Let $(\mathcal{T}_m, \Delta t_m)$ be a sequence of discretizations such that $(h_m, \Delta t_m)_m \rightarrow 0$. If we consider for each m the approximate solutions s_m , u_m and v_m , where $w_m = w_{\Delta t_m, h_m}$ and for $t \in [0, T]$

$$s_m(t) = s_{\Delta t_m}(t) = \sum_{k=0}^{N_T-1} \left(s^{k+1} + (t - t_{k+1}) \frac{s^{k+1} - s^k}{\Delta t} \right) \mathbf{1}_{[t_k, t_{k+1})}(t).$$

Theorem 2. *The sequence $(s_m, u_m, v_m)_m$ converges to (s, u, v) with*

$$\begin{aligned} w_m &\rightarrow w \text{ in } L^2(0, T; L^2(0, 1)), \\ \partial_{x, \mathcal{T}_m} w_m &\rightharpoonup \partial_x w \text{ in } L^2(0, T; L^2(0, 1)), \\ s_m &\rightarrow s \text{ in } \mathcal{C}([0, T]), \\ \partial_t s_m &\xrightarrow{w^*} s' \text{ in } L^\infty(0, T), \end{aligned}$$

and (s, u, v) is the weak solution to (2).

Sketch of the proof. First, we establish $L^2(0, T; H^1(0, 1))$ and $H^1(0, T; H^*)$ discrete estimates for $(u_m)_m$ and $(v_m)_m$, where H^* is the dual space to H . Then, thanks to a discrete version of the Aubin-Simon lemma [9], we obtain some compactness results for $(u_m, v_m)_m$ and the convergence of a subsequence towards some limit (u, v) . For the sequence $(s_m)_m$, we use Theorem 1 and the Ascoli theorem to show that $(s_m)_m$ converges to some function $s \in W^{1, \infty}(0, T)$. We also prove the convergence of the traces following [5]. Finally passing to the limit in the numerical scheme as in [4] we obtain that (s, u, v) is the weak solution to (2). As the system (2) admits a unique solution (see [1]), we deduce the convergence of the whole sequence (s_m, u_m, v_m) . $\square$

5 Numerical experiments

We consider the following test case:

κ_u	κ_v	g	r	s_0	u_0	v_0	α	γ	β
1	0.1	15	2.25	0.5	1	1	1	6.5	7.5

Table 1: Definition of the test case.

Fig 1 shows the different profiles of v and u as a function of $x \in [0, s(t)]$ for $t \in \{20, 40, 60, 80, 100\}$. We note that the profiles are similar to those given in [3, 10]. Fig 2 shows the behavior of s for $T = 100$ in linear scale and for $T = 1000$ in logarithmic scale. These numerical experiments support the $\sqrt{T}$ -law of propagation given in [3, 10].

Fig. 1: Profiles of v (on the left) and u at different times. The solutions are plotted on $[0, s(t)]$.

Fig. 2: Behavior of s in linear scale for $T = 100$ (on the left) and in logarithmic scale for $T = 1000$.

The exact solutions u and v of (2) are not explicitly known. Thus, in order to investigate the question of the L^∞ and L^2 -convergence rate in space of the scheme, we compute two reference solutions on a uniform mesh composed of 2560 cells and with $\Delta t = (1/2560)^2$. Then, we compute the L^∞ and L^2 -norm of the difference between the approximate solution and the average of the reference solution over 10, 20, 40, 80, 160, 320, 640 and 1280 cells. Eventually, in Table 2, we present the L^∞ and L^2 -convergence rate in space of the scheme at final time $T = 0.1$. As we can observe the scheme has an order around 2 in space, which is consistent with the choice of the Scharfetter-Gummel fluxes.
