THE GENERALIZED FRANCHETTA CONJECTURE
FOR SOME HYPER-KÄHLER VARIETIES

LIE FU, ROBERT LATERVEER, AND CHARLES VIAL,
with an appendix joint with MINGMIN SHEN

Abstract. We study the generalized Franchetta conjecture for holomorphic symplectic varieties. The conjecture predicts that the restriction of an algebraic cycle on the universal family of certain polarized hyper-Kähler varieties to a fiber is rationally equivalent to zero if and only if its cohomology class vanishes. We provide the following evidences: (1) The Beauville–Donagi family of Fano varieties of lines on cubic fourfolds; (2) The relative square, relative cube, relative Hilbert square and relative Hilbert cube of the universal families of K3 surfaces which are complete intersections in (weighted) projective spaces; (3) The relative product of the relative $r_1, \ldots, r_m$-th Hilbert powers of the universal family of quartic K3 surfaces, where $r_1 + \cdots + r_m \leq 5$; (4) The relative square and relative Hilbert square of the universal families of K3 surfaces of genera 6, 7, 8, 9, 10 and 12; (5) Relative square of the universal Fano variety of lines of the universal family of cubic fourfolds; (6) Zero-cycles and codimension 2 cycles for the Lehn–Lehn–Sorger–van Straten family of hyper-Kähler eightfolds. We also draw many consequences in the direction of the Beauville–Voisin conjecture as well as Voisin’s refinement for coisotropic subvarieties. In the appendix, we establish a new relation among tautological cycles on the square of the Fano variety of lines of a smooth cubic fourfold and provide some applications.

1. Introduction

The original Franchetta conjecture [13] (proven in [19], see also [25] and [2]) states the following:

**Theorem 1.1** ([13], [19], [25], [2]). Let \( g \geq 2 \) be an integer and \( M_g \) be the moduli space of smooth projective curves of genus \( g \). Denote by \( M^\circ_g \subset M_g \) the Zariski open subset parameterizing those curves without nontrivial automorphisms and by \( C \to M^\circ_g \) the universal curve. Then for any line bundle \( L \) on \( C \) and any \( b \in M^\circ_g \), the restriction of \( L \) to the fiber \( C_b \) is a multiple of the canonical bundle of \( C_b \).

In the case of the universal family of K3 surfaces \( S \to \mathcal{F}_g^\circ \), where \( \mathcal{F}_g^\circ \) is the moduli space of polarized K3 surfaces of genus \( g \) without non-trivial automorphisms, O’Grady proposed in [32] the following analogue of the Franchetta conjecture. Recall that the Beauville–Voisin class ([7]) of a projective K3 surface \( S \) is the 0-cycle class \( o_S \) represented by any point on a rational curve of the K3 surface. It enjoys the property that the intersections of any two divisors, as well as the second (Chow-theoretic) Chern class of \( S \), are multiples of \( o_S \).

**Conjecture 1.2** (O’Grady [32]). Notation is as above. Then for any algebraic cycle \( z \in CH^2(S) \) and any point \( b \in \mathcal{F}_g^\circ \), the restriction of \( z \) to the fiber K3 surface \( S_b \) is a multiple of the Beauville–Voisin class of \( S_b \).

Using Mukai models, Conjecture 1.2 is verified in [33] for K3 surfaces with genus \( g \leq 10 \) and \( g = 12, 13, 16, 18, 20 \). Otherwise, Conjecture 1.2 is still wide open.

The main goal of the paper is to investigate the following higher dimensional analogue of O’Grady’s Conjecture 1.2 concerning projective hyper-Kähler varieties. Recall that a smooth projective variety is called hyper-Kähler or irreducible holomorphic symplectic, if it is simply connected and \( H^2,0 \) is generated by a nowhere degenerate holomorphic 2-form.

**Conjecture 1.3** (Generalized Franchetta Conjecture, cf. [8]). Let \( F \) be the moduli space of polarized hyper-Kähler varieties of a given type, \( F^\circ \) be its open subset parametrizing hyper-Kähler varieties with trivial automorphism groups and \( X^\circ \to F^\circ \) be the universal family. For any \( z \in CH(X^\circ)_Q \), if its restrictions to the very general fibers are homologically trivial then its restriction to any fiber is (rationally equivalent to) zero.

One could also be optimistic and expect that Conjecture 1.3 holds more generally for self-products of hyper-Kähler varieties, i.e., for any \( z \in CH(X^\circ \times_{F^\circ} \cdots \times_{F^\circ} X^\circ)_Q \), if its restrictions to the very general fibers are homologically trivial then its restriction to any fiber is (rationally equivalent to) zero. We provide some evidence in Theorems 1.4, 1.5, 1.11 and 1.12 below.

Recently, Bergeron and Li [8] proven the cohomological version of the generalized Franchetta Conjecture 1.3 for relative 0-cycles when the second Betti number is sufficiently large, which is an important support in favor of the conjecture.

Let us also mention that Conjecture 1.3 is closely related to the so-called Beauville–Voisin conjecture and its refinement (see Conjecture 2.3 and 2.4). On the one hand, the proof of some of our main results actually uses some known cases of Beauville–Voisin conjecture (especially [41]) ; on the other hand, the Generalized Franchetta Conjecture implies the part of Beauville–Voisin conjecture involving only Chern classes and the polarization, see Proposition 2.5.

We outline the main results of the paper, which provide more evidences for the Generalized Franchetta Conjecture 1.3.
1.1. Powers and Hilbert powers of some K3 surfaces. We can establish Conjecture 1.3 for the relative squares and cubes, as well as the relative Hilbert squares and Hilbert cubes, of the universal family of K3 surfaces which are complete intersections in projective spaces.

Theorem 1.4. Let $B^o$ be the parameter space of smooth K3 surfaces of genus $g = 3, 4$ or $5$, and let $S^o \to B^o$ be the universal family. Let $X^o$ be $S^o \times_B S^o$, $S^o \times_B S^o \times_B S^o$, $S^o \times_B S^o \times_B S^o \times_B S^o$, $S^o \times_B S^o$, $S^o \times_B S^o$, $S^o \times_B S^o$ or $S^o \times_B S^o$. For any cycle $z \in \text{CH}(X^o)_Q$ and any $b \in B^o$, the restriction of $z$ to the fiber $X_b$ is zero if and only if it is numerically trivial.

The proof will be given in §4 for squares and Hilbert squares and in §5.2 for the other cases. We note that, thanks to the result of de Cataldo and Migliorini [11], the crucial cases are the self-products $S^o \times_B S^o$, $S^o \times_B S^o \times_B S^o$. This is in line with our optimistic expectation that the generalized Franchetta conjecture should hold for self-products of hyper-Kähler varieties.

By pushing our techniques further (cf. §5.1), we can also treat some other cases of (Hilbert) powers of K3 surfaces:

Theorem 1.5. The Generalized Franchetta Conjecture 1.3 holds for

(i) $S \times_B S$, $\text{Hilb}_B^2 S$, $S \times_B S \times_B S$, $S \times_B \text{Hilb}_B^2 S$ and $\text{Hilb}_B^3 S$, where $S \to B$ is the universal family of smooth K3 surfaces of genus 2 (double planes).

(ii) $\text{Hilb}_B^k S \times_B \cdots \times_B \text{Hilb}_B^r S$, where $S \to B$ is the universal family of smooth quartic K3 surfaces and $r_1 + \cdots + r_m \leq 5$.

(iii) The relative square and relative Hilbert square of the universal family of K3 surfaces of genera 6, 7, 8, 9, 10, 12.

The proof will be given in §5.3, where these results are just special cases of the more general but more technical Theorem 5.6. See also Remark 5.7 which explains that the ranges in Theorems 1.4 and 1.5 above are, at least most of them, already at the limit of our method.

As immediate consequences, we obtain some partial confirmation of Voisin’s refinement of the Beauville–Voisin conjecture involving coisotropic subvarieties (Conjecture 2.4):

Corollary 1.6. Let $S$ be a general K3 surface of genus $g \leq 10$ or 12, and let $X$ be the Hilbert square $X = S^{[2]}$. Let $R(X) \subset \text{CH}(X)_Q$ denote the $Q$-subalgebra generated by the polarization class $h$, the Chern classes $c_i$, and the Lagrangian surface $T \subset X$ constructed in [20, Proposition 4]. Then $R^*(X)$ injects into cohomology by the cycle class map.

Corollary 1.7. Let $S \subset \mathbb{P}^3$ be a quartic K3 surface, and let $X = S^{[3]}$, $S^{[2]} \times S^{[2]} \times S$, $S^{[2]} \times S^3$ or $S^{[2]} \times S^{[3]}$. Let $R(X) \subset \text{CH}(X)_Q$ denote the $Q$-subalgebra generated by the polarization class $h$, the Chern classes $c_i$, the coisotropic subvarieties $E_{\mu}$ of [44, 4.1 item 1]), the Lagrangian surface $T \subset S^{[2]}$ constructed in [20, Proposition 4], and the surface of bitangents $U \subset S^{[2]}$. Then $R^*(X)$ injects into cohomology by the cycle class map.

Corollary 1.8. Let $S \subset \mathbb{P}^4$ be a general K3 surface of degree 6, and let $X = S^{[3]}$. Let $R(X) \subset \text{CH}(X)_Q$ denote the $Q$-subalgebra generated by the polarization class $h$, the Chern classes $c_i$, the coisotropic subvarieties $E_{\mu}$ of [44, 4.1 item 1]), and the indeterminacy locus $I \subset X$ of the birational anti–symplectic involution of Beauville [3] (so I $\cong \mathbb{P}^3$). Then $R^*(X)$ injects into cohomology by the cycle class map.

These three corollaries are proven in §5.3 and also partially extended to products of Hilbert schemes in Corollary 5.8. A similar application to a 19–dimensional family of double EPW sextics is given in §5.5.
Another consequence, whose proof as well as the background is in \cite{5,6}, concerns the Bloch conjecture for the anti–symplectic involution on Hilbert squares of quartic surfaces constructed by Beauville \cite{3}:

**Corollary 1.9.** Let $X = S^{[2]}$ be the Hilbert square of a quartic $K3$ surface $S$, and let $\iota$: $X \to X$ be the anti–symplectic involution of Beauville \cite{3}. Then

\[
\iota^* = -\text{id}: \quad \text{CH}^i(X)_{(2)} \to \text{CH}^i(X)_{(2)} \quad (i = 2, 4),
\]

\[
\iota^* = \text{id}: \quad \text{CH}^i(X)_{(j)} \to \text{CH}^i(X)_{(j)} \quad (j = 0, 4).
\]

(Here, the notation $\text{CH}^i(X)_{(\iota)}$ refers to the Fourier decomposition of $\text{CH}(X)_{\mathbb{Q}}$ constructed by Shen–Vial \cite{35}.)

1.2. **Beauville–Donagi family.** For the universal family of Fano varieties of lines, which form a complete family of projective hyper-Kähler fourfolds of $K3^{[2]}$-type \cite{6}, we have the following slightly stronger result than predicted by Conjecture 1.3:

**Theorem 1.10.** Let $B^o$ be the parameter space of smooth cubic fourfolds, $X^o \to B^o$ be the universal family and $\mathcal{F}^o \to B^o$ be the universal family of Fano varieties of lines of the fibers of $X^o/B^o$. Then for any $i \in \mathbb{N}$, any $z \in \text{CH}^i(\mathcal{F}^o)_{\mathbb{Q}}$ and any $b \in B^o$, the restriction of $z$ to the fiber $F_b$ is numerically trivial if and only if it is (rationally equivalent to) zero.\footnote{In fact, we show that the restriction of $\text{CH}^i(\mathcal{F}^o)_{\mathbb{Q}}$ to $\text{CH}^i(F_b)_{\mathbb{Q}}$ is the tautological subring, which is defined as the $\mathbb{Q}$-subalgebra generated by the Plücker polarization of $F_b$ and by the Chern classes of $F_b$, see Remark 3.3.}

In order to study the next case (Theorem 1.12), we also prove the following analogous result on the relative square of the universal family of Fano varieties of lines:

**Theorem 1.11.** Notation is as in Theorem 1.10. Then for $z \in \text{CH}^i(\mathcal{F}^o \times_{B^o} \mathcal{F}^o)_{\mathbb{Q}}$ and any $b \in B^o$, the restriction of $z$ to the fiber $F_b \times F_b$ is numerically trivial if and only if it is (rationally equivalent to) zero.\footnote{We actually show that the restriction of $\text{CH}^i(\mathcal{F}^o \times_{B^o} \mathcal{F}^o)_{\mathbb{Q}}$ to $\text{CH}(F_b \times F_b)_{\mathbb{Q}}$ is the tautological subring, which is defined as the $\mathbb{Q}$-subalgebra generated by the tautological subrings of the two factors together with the classes of the diagonal and the incidence subvariety; see Proposition 6.2.}

The proof of Theorem 1.10 (resp. Theorem 1.11) consists of two steps. First we show that cycles that belong to the image of the restriction map $\text{CH}^i(\mathcal{F}^o)_{\mathbb{Q}} \to \text{CH}^i(F_b)_{\mathbb{Q}}$ (resp. $\text{CH}^i(\mathcal{F}^o \times_{B^o} \mathcal{F}^o)_{\mathbb{Q}} \to \text{CH}^i(F_b \times F_b)_{\mathbb{Q}}$) are tautological in the sense of Remark 3.3 (resp. Definition 6.2). Second we show that relations among tautological cycles modulo numerical equivalence in fact hold modulo rational equivalence. More precisely, we determine completely in terms of generators and relations the rings of tautological cycles for $F_b$ and $F_b \times F_b$. In the case of $F_b \times F_b$, all relations but one had been established in \cite{41} and \cite{35}. The remaining relation is established in a joint appendix with Mingmin Shen, where we also draw some consequences concerning the multiplicative properties of the Chow motive of $F_b$.

1.3. **Lehn–Lehn–Sorger–van Straten family.** Similarly to the Fano varieties of lines of cubic fourfolds, Lehn–Lehn–Sorger–van Straten (LLSvS) consider in \cite{24} the twisted cubic curves on a cubic fourfold not containing a plane and show that the base of the maximal rationally connected (MRC) quotient of the moduli space of such curves is a hyper-Kähler eightfold. Later Addington and M. Lehn show in \cite{2} that this hyper-Kähler eightfold is of $K3^{[3]}$-deformation type. For the universal family of LLSvS hyper-Kähler eightfolds, we have the following result, which confirms the zero-cycle and codimension-2 cycle cases of the Generalized Franchetta Conjecture\cite{1,3}.

\[1\]
Theorem 1.12. Let $B^{\circ}$ be the parameter space of smooth cubic fourfolds not containing a plane and let $Z \to B^{\circ}$ be the universal family of LLSvS hyper-Kähler eightfolds ([24]). Then

(i) for any $b \in B^{\circ}$ and for any $\gamma \in \text{CH}^8(Z)$ which is fiber-wise of degree 0, the restriction of $\gamma$ to the fiber $Z_b$ is (rationally equivalent to) zero.

(ii) for any $b \in B^{\circ}$ and for any $\gamma \in \text{CH}^2(Z)_Q$, its restriction to the fiber $Z_b$ is zero if and only if its cohomology class vanishes.

As a consequence, we deduce a part of the Beauville–Voisin Conjecture 2.3 as well as the refined Conjecture 2.4 for LLSvS eightfolds:

Corollary 1.13. Given any smooth cubic fourfold $X$ which does not contain a plane, let $Z$ be the LLSvS hyper-Kähler eightfold associated to $X$. Denote by $h$ the polarsubalgebraization class. Then the classes

$$h^8, c_2 h^6, c_2^2 h^4, c_2^3 h^2, c_4 h^4, c_2 c_4 h^2, c_2^2 c_4, c_6 h^2, c_2 c_6, c_4^2 c_2, c_8 \in \text{CH}_0(Z)_Q$$

are all proportional, where $c_i := c_i(T_Z)$ is the $i$-th (Chow-theoretic) Chern class of the tangent bundle of $Z$. We call the generator of degree 1 in this one-dimensional subspace the canonical 0-cycle class or the Beauville–Voisin class of $Z$, denoted by $\mathcal{o}_Z$.

More strongly, let $R(Z)$ be the $\mathbb{Q}$-subalgebra generated by the polarization class $h$, the Chern classes $c_i$ together with the following classes of coisotropic subvarieties of $Z$:

- the embedded cubic fourfold $X \subset Z$ ([24]);
- the space of twisted cubics contained in a general hyperplane section of $X$ ([37]);
- the coisotropic subvarieties of codimension 1, 2, 3, 4 constructed by Voisin ([44, Corollary 4.9]);
- the fixed locus of the anti-symplectic involution $\iota$ of $Z$ ([22]);
- the images by $\iota$ of all the above subvarieties.

Then $R^8(Z) = \mathbb{Q} \cdot \mathcal{o}_Z$.

Conventions. All algebraic varieties are over the field of complex numbers. We work with Chow groups with rational coefficients. For the $m$-th Hilbert scheme of a surface $S$, the two notations $S^{[m]}$ and $\text{Hilb}^m(S)$ are used interchangeably and similarly for the relative situation.

Acknowledgements. The authors want to thank Nicolas Addington, Zhiyuan Li, Renjie Lyu, Nicolas Ressayre, Qizheng Yin for their interest and helpful comments and discussions.

2. General remarks

2.1. Generic fiber vs. geometric fibers. There is the following slightly different version of the generalized Franchetta conjecture for hyper-Kähler varieties:

Conjecture 2.1. Let $\mathcal{F}$ be the moduli space of polarized hyper-Kähler varieties and let $\pi : \mathcal{X} \to \mathcal{F}$ be the universal family. Denote by $\mathcal{X}_\eta$ the generic fiber of $\pi$, where $\eta = \text{Spec}(\mathcal{C}(\mathcal{F}))$. Then the group $\text{CH}^*(\mathcal{X}_\eta)_{\text{hom}}$ is torsion.

Here homological equivalence is with respect to some classical Weil cohomology, for instance, étale cohomology or de Rham cohomology.

Lemma 2.2. Conjecture 1.3 and Conjecture 2.1 are equivalent.

Proof. Let us start by assuming Conjecture 1.3. Since $\text{CH}(\mathcal{X}_\eta) = \lim_{\longrightarrow} \text{CH}(\mathcal{X}_U)$, where $U$ runs through all non-empty Zariski open subset of the moduli space $\mathcal{F}$, for a given cycle $z_\eta \in \text{CH}(\mathcal{X}_\eta)$,
we can assume it comes from the universal family over a Zariski open subset $F^\circ$ of $F$, namely, $z \in \text{CH}(X^\circ)$. Using [38, Lemma 2.1], the hypothesis that the restriction of $z$ to the geometric generic fiber is homologically trivial implies that the restriction of $z$ to every very general geometric fiber is also trivial. Now the conclusion of Conjecture [1.3] says that the restriction of $z$ to a very general geometric fiber is (rationally equivalent to) zero. By the standard argument of decomposition of the diagonal ([9], [40], [43]), this implies the existence of a Zariski open dense subset $U \subset F$, such that $z|_{X^\circ_U}$ is zero. In particular, $z_\eta$ is rationally equivalent to zero.

For the other direction, since we know that $\text{CH}^*(X_\eta)$ is torsion, by restriction we can show Conjecture [1.3] for general fibers. Then a standard specialization argument allows us to conclude for all fibers.

Thanks to Lemma [2.2], we will focus in this paper on Conjecture [1.3].

2.2. Relation to Beauville–Voisin conjecture. As is mentioned in the introduction, the Generalized Franchetta Conjecture [1.3] is very much related to the following Beauville–Voisin conjecture:

Conjecture 2.3 (Beauville–Voisin [5], [41]). Let $X$ be a projective hyper-Kähler variety. Let the Beauville–Voisin subring $\langle c_i(X), \text{Pic}(X) \rangle$ be the $\mathbb{Q}$-subalgebra of $\text{CH}^*(X)$ generated by line bundles and all (Chow theoretic) Chern classes of $T_X$. Then the restriction of the cycle class map to the Beauville–Voisin subring is injective. In other words, any polynomial of line bundles and Chern classes of $X$ is homologically equivalent to zero if and only if it is rationally equivalent to zero.

The original version due to Beauville in [5], under the name of weak splitting property, contains only line bundles; the Chern classes of the tangent bundle are introduced by Voisin in [41]. Some active progress towards this conjecture has recently been made: see [5], [41], [15], [45], [34], [17, Theorem 1.14] for the known results and more details. More recently, Voisin [44] proposes the following stronger version of Conjecture 2.3 involving the coisotropic subvarieties (in particular lagrangian subvarieties):

Conjecture 2.4 (Voisin’s refinement [44]). Let $X$ be a projective hyper-Kähler variety. Then the restriction of the cycle class map to the $\mathbb{Q}$-subalgebra of $\text{CH}(X)$ generated by line bundles, Chern classes of $T_X$ and coisotropic subvarieties, is injective.

We would like to point out that the generalized Franchetta conjecture implies the part of the Beauville–Voisin conjecture involving only the Chern classes of the tangent bundle and the polarization class. More generally it actually implies part of the refined Conjecture 2.4 once taking into account coisotropic subvarieties which are defined universally over the moduli space (see Corollaries [1.6], [1.7], [1.8], [5.9] and [1.13] for examples):

Proposition 2.5. Let $\mathcal{F}$ be a moduli space of polarized hyper-Kähler varieties. If Conjecture [1.3] holds true for the universal family over $\mathcal{F}$, then for any member $X$ of this family, the cycle class map restricted to the $\mathbb{Q}$-subalgebra generated by the polarization line bundle and the Chern classes of $T_X$, is injective. More generally, still assuming Conjecture [1.3] for any member $X$ of this family, the cycle class map restricted to the $\mathbb{Q}$-subalgebra generated by the algebraic cycles of $X$ that exist universally over the moduli space, is injective.

Proof. Let $X^\circ \to \mathcal{F}^\circ$ be the universal family, where $\mathcal{F}^\circ \subset \mathcal{F}$ is an open subset. For any member $X$ and any given polynomial of polarization line bundle and Chern classes of the tangent bundle $z := P(h, c_i(T_X)) \in \text{CH}(X)$ such that the cohomology class of $z$ vanishes, we want to show that $z = 0$. Consider $\gamma := P(h, c_i(T_{X^\circ/r^\circ})) \in \text{CH}(X^\circ)$. If $X$ belongs to $\mathcal{F}^\circ$, then clearly $\gamma|_X = z$ and hence $\gamma$ has fiber-wise vanishing cohomology class. Then the generalized Franchetta conjecture [1.3] says exactly
that $z$ is rationally equivalent to zero. If $X$ does not belong to $\mathcal{F}^\circ$, the specialization argument for algebraic cycles allows us to conclude. The last assertion is more or less tautological. □

2.3. Moduli space vs. parameter space.

Remark 2.6. To show the Generalized Franchetta Conjecture 1.3 in some cases, it will be convenient to work over some parameter space which dominates the moduli space, instead of the moduli space itself. More precisely, keep the same notation as in Conjecture 1.3 and let $B \rightarrow U$ be a surjective morphism to some Zariski dense open subset $U$ of the moduli space $\mathcal{F}^\circ$. Denote by $\mathcal{Y} \rightarrow B$ the pulled-back family of the universal family $X^\circ \rightarrow \mathcal{F}^\circ$. Then the generalized Franchetta conjecture for $\mathcal{Y} \rightarrow B$ implies the generalized Franchetta conjecture for $X^\circ \rightarrow \mathcal{F}^\circ$.

\[
\begin{array}{cccc}
\mathcal{Y} & \rightarrow & X_U & \leftarrow & X^\circ \\
\downarrow & & \downarrow & & \downarrow \\
B & \rightarrow & U & \leftarrow & \mathcal{F}^\circ
\end{array}
\]

Indeed, for any $z \in \text{CH}(X^\circ)$, denote by $z' \in \text{CH}(\mathcal{Y})$ its pull-back image in $\mathcal{Y}$. Obviously, the hypothesis that the restriction of $z$ to a very general fiber of $X^\circ / \mathcal{F}^\circ$ is homologically trivial implies the same thing for the restriction of $z'$ to the fibers of $\mathcal{Y} / B$. The generalized Franchetta conjecture for $\mathcal{Y} / B$ then implies that $z'$ restricts to zero on each fiber of $\mathcal{Y} / B$. Hence so is $z$ for each fiber of $X_U \rightarrow U$. A specialization argument shows that the same thing holds for each fiber of $X^\circ \rightarrow \mathcal{F}^\circ$.

3. Fano varieties of lines of cubic fourfolds

In this section, we prove Theorem 1.10, which by Remark 2.6 confirms the Generalized Franchetta Conjecture 1.3 for the 20-dimensional complete family of hyper-Kähler fourfolds constructed by Beauville–Donagi in [6]. The key idea of the proof is as in [42] and [33]: the universal family has very simple Chow groups.

We start by setting up some notations. Let $V$ be a 6-dimensional vector space and $\mathbb{P}^5 = \mathbb{P}(V)$ be its projectivization. The parameter space of possibly singular cubic fourfolds is given by the following projective space:

$$B := \mathbb{P}(H^0(\mathbb{P}^5, O(3))) = \mathbb{P}(\text{Sym}^3 V^\vee) \cong \mathbb{P}^{55}.$$ 

Let $B^\circ \subset B$ be the open subset parameterizing smooth cubic fourfolds. We thus have the universal family $X \rightarrow B$ as well as the smooth family $X^\circ \rightarrow B^\circ$ by base-change.

Let $G := \text{Gr}(\mathbb{P}^1, \mathbb{P}^5) \cong \text{Gr}(2, 6)$ be the Grassmannian variety parameterizing all projective lines in $\mathbb{P}^5$. Denote by $S$ (resp. $Q$) the tautological rank-2 subbundle (resp. rank-4 quotient bundle), fitting into the following short exact sequences of vector bundles over $G$:

$$0 \rightarrow S \rightarrow O_G \otimes V \rightarrow Q \rightarrow 0.$$ 

Note that for any equation $f \in \text{Sym}^3 V^\vee$, the above short exact sequence gives a section $s_f$ of the vector bundle $\text{Sym}^3 S^\vee$, whose zero locus ($s_f = 0$) is exactly the Fano variety of lines of the cubic fourfold defined by $f$.

Consider the incidence subvariety $\mathcal{F}$ in $B \times G$ defined by

$$\mathcal{F} := \{(l, f) \in B \times G \mid f|_l = 0\},$$
together with the two natural projections:

\[ \begin{array}{ccc}
\pi & \quad \mathcal{F} \\
B & \downarrow & \quad G \\
p & \quad & \end{array} \]

It is easy to see that \( \pi : \mathcal{F} \to B \) is the universal Fano variety of lines of fibers of \( X/B \) and that \( p : \mathcal{F} \to G \) is a projective bundle whose fiber over a line \( l \in G \) parametrizes all (possibly singular) cubic fourfolds containing \( l \).

As in [33, Lemma 2.1], we have the following:

**Lemma 3.1.** For any \( b \in B \), the following two images of restriction maps are the same:

\[ \text{Im} (\text{CH}(\mathcal{F}) \to \text{CH}(F_b)) = \text{Im} (\text{CH}(G) \to \text{CH}(F_b)). \]

**Proof.** The inclusion \( \supseteq \) is trivial (we have the factorization \( F_b \to \mathcal{F} \to G \)).

Let us show the inverse inclusion. Given any cycle \( z \in \text{CH}(\mathcal{F}) \), by the projective bundle formula,

\[ z = \sum_{k \geq 0} p^*(z_k) \cdot \xi^k, \]

where \( z_k \in \text{CH}(G) \) and \( \xi = c_1(O_p(1)) \). As in [33, Lemma 2.1], we easily check that \( \xi \) is a linear combination of cycles pulled back from \( B \) by \( \pi \) and cycles pulled back from \( G \) by \( p \). Hence \( z \) is a polynomial of cycles of the form \( p^*(a) \) and \( \pi^*(b) \). The latter type being zero when restricted to any fiber \( F_b \), the restriction of \( z \) to \( F_b \) is therefore the restriction of some cycle of \( G \). \( \square \)

**Lemma 3.2.** For any \( b \in B^o \),

\[ \text{Im} (\text{CH}(G) \to \text{CH}(F_b)) \subseteq \langle c_i(F_b), \text{Pic}(F_b) \rangle, \]

where the right hand side is the Beauville–Voisin subring of \( \text{CH}(F_b) \) generated (as a \( Q \)-algebra) by line bundles and all Chern classes of the tangent bundle of \( F_b \).

**Proof.** Since \( \text{CH}(G) \) is generated (as a \( Q \)-algebra) by \( c_1(S^V) \) and \( c_2(S^V) \), it suffices to show that both of their restrictions to \( F_b \) lie in the Beauville–Voisin ring. The first one being a line bundle, it remains to show \( c_2(S^V|_{F_b}) \in \langle c_i(F_b), \text{Pic}(F_b) \rangle \). However, using the short exact sequence

\[ 0 \to T_{F_b} \to T|_{F_b} \to \text{Sym}^3 S^V|_{F_b} \to 0 \]

together with \( T_G \simeq S^V \otimes Q \), one finds that

\[ ch(T_{F_b}) = ch(S^V|_{F_b}) \left( 6 - ch(S|_{F_b}) \right) - ch\left( \text{Sym}^3 S^V|_{F_b} \right), \]

and hence \( c_2(T_{F_b}) = -ch_2(T_{F_b}) = 5c_1(S^V|_{F_b})^2 - 8c_2(S^V|_{F_b}) \). Therefore, \( c_2(S^V|_{F_b}) \) also belongs to the Beauville–Voisin ring. \( \square \)

We can now easily conclude:

**Proof of Theorem 1.10.** For any \( z \in \text{CH}(F^o) \), by the surjectivity of \( \text{CH}(\mathcal{F}) \to \text{CH}(F^o) \), we can actually assume that \( z \in \text{CH}(\mathcal{F}) \). For any \( b \in B^o \), thanks to Lemma 3.1, \( z|_{F_b} \) is the restriction of some cycle from \( G \), which must lie in the Beauville–Voisin ring \( \langle c_i(F_b), \text{Pic}(F_b) \rangle \) by Lemma 3.2. Now the equivalence between homological triviality and rational triviality of \( z|_{F_b} \) is a consequence of Voisin’s result [41, Theorem 1.4(ii)] saying that the cycle class map restricted to the Beauville–Voisin ring.
ring is injective. Finally, numerical equivalence and homological equivalence coincide for Fano varieties of lines of cubic fourfolds by [10]. □

**Remark 3.3.** In fact, the above proof shows that the restriction of a cycle \( z \in \text{CH}(F) \) to a fiber Fano variety of lines \( F \) is in the so-called tautological ring \( R^*(F) \), which is the \( \mathbb{Q} \)-subalgebra of \( \text{CH}^*(F) \), in general smaller than the Beauville–Voisin ring, generated by the Plücker polarization class \( g \) and the Chern classes of \( F \). In particular,

- \( R^1(F) = \mathbb{Q} \cdot g \);
- \( R^2(F) = \mathbb{Q} \cdot g^2 \oplus \mathbb{Q} \cdot c_2 \);
- \( R^3(F) = \mathbb{Q} \cdot g^3 \) (by [41] Lemma 3.5 \( gc_2 \) and \( g^3 \) are proportional);
- \( R^4(F) = \mathbb{Q} \cdot \varphi_F \), where \( \varphi_F \) is the canonical 0-cycle class and \( c_2^2, c_4, g^4, g^2 c_2 \) are all proportional to it by [41] Lemma 3.2.

### 4. Hilbert squares of complete intersection K3 surfaces

In this section, we prove Theorem 1.4 for squares and Hilbert squares. There are three families of complete intersection K3 surfaces, namely, quartic surfaces in \( \mathbb{P}^3 \), complete intersections of quadric and cubic hypersurfaces in \( \mathbb{P}^4 \) and complete intersections of three quadric hypersurfaces in \( \mathbb{P}^5 \).

Let us fix some notations: in each of the three cases

- \( P := \mathbb{P}^3, \mathbb{P}^4 \) resp. \( \mathbb{P}^5 \) is the ambient projective space;
- \( E := \mathcal{O}_P(4), \mathcal{O}_P(2) \oplus \mathcal{O}_P(3), \) resp. \( \mathcal{O}_P(2)^{\oplus 3} \) is the relevant vector bundle;
- \( B := \text{Pic}(\mathbb{P}, E) \) is the parameter (projective) space and \( B^0 \) is the open subset parameterizing smooth K3 surfaces.
- \( S := \{(x,[s]) \in \mathbb{P} \times B \mid s(x) = 0\} \) is the universal family.

We have therefore the natural projections, where \( p \) is clearly a projective bundle;

\[
\begin{array}{ccc}
S & \overset{p}{\longrightarrow} & \mathbb{P} \\
\downarrow \pi & & \downarrow \\
B & & 
\end{array}
\]

Similarly, the relative square and the open complement of the relative diagonal in it fit into the following diagram

\[
\begin{array}{ccc}
S \times_B S & \overset{q'}{\longrightarrow} & \mathbb{P} \times \mathbb{P} \\
\downarrow i & & \downarrow \\
[S \times_B S] \setminus \Delta_{S/B} & \overset{q}{\longrightarrow} & \mathbb{P} \times \mathbb{P} \setminus \Delta \mathbb{P} \\
\downarrow \pi_2 := (\pi, \pi) & & \downarrow \\
S \times_B S & \overset{q = (p,p)}{\longrightarrow} & \mathbb{P} \times \mathbb{P} \\
\downarrow \pi_2 := (\pi, \pi) & & \downarrow \\
B & & 
\end{array}
\]

Note that although \( q \) itself is not a projective bundle, its restriction \( q' \) is. Let \( \xi \) be the first Chern class of \( \mathcal{O}_p(1) \). The relative diagonal \( \Delta_{S/B} \) being of codimension 2, \( \xi \) extends uniquely to the whole \( S \times_B S \), which we still denote by \( \xi \) by abuse of notation.
We can show the analogue of Lemma 3.1 in our case:\footnote{Proposition 4.1 will be generalized for the so-called stratified projective bundle in §5.1.}

**Proposition 4.1.** For any \( b \in B^* \), we have:

\[
\text{Im}(\text{CH}(S \times_B S) \to \text{CH}(S_b \times S_b)) = \text{Im}(\text{CH}(P \times P) \to \text{CH}(S_b \times S_b)) + \Delta, \text{Im}(\text{CH}(P) \to \text{CH}(S_b)),
\]

where \( \Delta : S_b \to S_b \times S_b \) is the diagonal embedding.

**Proof.** Notation is as in Diagrams (1) and (2). By base-change, it is easy to see that the right-hand side is contained in the left-hand side. Concerning the inverse inclusion, the projective bundle formula gives, for any \( z \in \text{CH}(S \times_B S) \),

\[
j^*(z) = \sum_{k \geq 0} q^*(z_k) \cdot \xi^k,
\]

for some cycles \( z_k \in \text{CH}(P \times P) \setminus \Delta_P \). As in Lemma 3.1, it is easy to see that \( \xi = j \pi_2^*(h) + q^*(\alpha) \), where \( h = c_1(O_B(1)) \) and \( \alpha \in \text{CH}(P \times P) \setminus \Delta_P \). For each \( k \), we denote still by \( z_k \in \text{CH}(P \times P) \) its closure and similarly for \( \alpha \). Therefore, we have

\[
z - \sum_k q^*(z_k) \cdot \left( \pi_2^*(h) - q^*(\alpha) \right)^k \in \ker(j^*).
\]

By the localization sequence, there exists \( \gamma \in \text{CH}(S) \), such that

\[
(3) \quad z - \sum_k q^*(z_k) \cdot \left( \pi_2^*(h) - q^*(\alpha) \right)^k = \Delta_*(\gamma),
\]

where \( \Delta : S \to S \times_B S \) is the diagonal embedding.

Since \( p : S \to P \) is also a projective bundle with \( c_1(O_P(1)) = \pi^*(h) \), we have

\[
\gamma = \sum_l p^*(\gamma_l) \cdot \pi^*(h)^l,
\]

for some \( \gamma_l \in \text{CH}(P) \). Substituting this into (3), we get

\[
(4) \quad z = \sum_k q^*(z_k) \cdot \left( \pi_2^*(h) - q^*(\alpha) \right)^k + \sum_l \Delta_*(p^*(\gamma_l) \cdot \pi^*(h)^l),
\]

Now for any \( b \in B^* \), the restriction \( z|_{S_b \times S_b} \) is of the desired form simply because the restrictions of \( \pi_2^*(h) \) and \( p^*(h) \) to the fibers vanish. \qed

**Proof of Theorem 1.4 for relative squares.** Keep the same notations as before. Thanks to Proposition 4.1, we only need to show that for any smooth complete intersection K3 surface \( S \subset P \), the cycle class map restricted to \( \text{Im}(\text{CH}(P \times P) \to \text{CH}(S \times S)) + \Delta, \text{Im}(\text{CH}(P) \to \text{CH}(S)) \) is injective. Denote \( H := c_1(O_P(1)) \) and \( h := H|_S \). Since \( \text{CH}(P \times P) \) is generated by \( \text{pr}_1^*(H) \) and \( \text{pr}_2^*(H) \), and \( \Delta(h) = h \circ s + s \circ h \) (see [2]), it is enough to show that the cycle class map of \( S \times S \) restricted to the subalgebra generated by \( \text{pr}_1^*(h), \text{pr}_2^*(h) \) and \( \Delta \) is injective. It is the easiest case of Voisin’s [41], Proposition 2.2. \qed
Proof of Theorem 1.4 for relative Hilbert squares. Consider the blow-up of $S^\circ \times_{B^\circ} S^\circ$ along the relative diagonal $\Delta_{S^\circ/B^\circ}$, the natural involution switching two factors lifts to the blow-up. It is well-known that the Hilbert square is the quotient of this lifted involution and

$$\text{CH}'(\text{Hilb}^2_{B^\circ}(S^\circ)) = \text{CH}'(\text{Bl}_A (S^\circ \times_{B^\circ} S^\circ))^{\text{inv}} \cong \text{CH}'(S^\circ \times_{B^\circ} S^\circ)^{\text{inv}} \oplus \text{CH}^{-1}(S^\circ),$$

where all isomorphisms are compatible with the restriction to the fibers. Therefore for any $b \in B^\circ$ and any $z \in \text{CH}'(\text{Hilb}^2_{B^\circ}(S^\circ))$, its restriction to the fiber $z|_{\text{Hilb}^2_{S^\circ} S^\circ}$, viewed as an element in $\text{CH}'(S_b \times_{S_b} S_b)^{\text{inv}} \oplus \text{CH}^{-1}(S_b)$, lives in $\text{Im}(\text{CH}(S^\circ \times_{B^\circ} S^\circ)^{\text{inv}} \to \text{CH}'(S_b \times_{S_b} S_b)^{\text{inv}} \oplus \text{Im}(\text{CH}^{-1}(S^\circ) \to \text{CH}^{-1}(S_b))$. We can thus conclude thanks to the established cases of the generalized Franchetta conjecture for the relative squares $S^\circ \times_{B^\circ} S^\circ$ and for $S^\circ$.

\[\square\]

5. Some more cases of Hilbert schemes of K3 surfaces

In this section, we try to push the results of §4 to higher (Hilbert) powers and to K3 surfaces of higher genera. Let us first provide the technical tool.

5.1. Stratified projective bundle. As one can observe the similarity between Lemma 3.1 and Proposition 4.1 (also Proposition 6.1 later), the goal of this technical subsection is to summarize these situations.

**Definition 5.1** (Stratified projective bundle). A projective morphism $q : X \to Y$ is called a stratified projective bundle if there exists a commutative cartesian diagram

\[
\begin{array}{ccc}
X_r & \cdots & X_1 & \xrightarrow{q_1} & X_0 = X \\
\downarrow q_r & & \downarrow q_1 & & \downarrow q_0 = q \\
Y_r & \cdots & Y_1 & \xrightarrow{q_1} & Y_0 = Y
\end{array}
\]

where all horizontal morphisms are closed immersions, such that for any $0 \leq i \leq r$, the restriction of $q_i$

$$q_i' : X_i \setminus X_{i+1} \to Y_i \setminus Y_{i+1}$$

is a projective bundle ($X_{r+1} = Y_{r+1} = \emptyset$). The above diagram is called a stratification of $q$.

Now we can state the following generalization of Lemma 3.1 and Proposition 4.1 (see also Proposition 6.1 for an example).

**Proposition 5.2.** Let $q : X \to Y$ be a stratified projective bundle with a given stratification \((5)\) and $\pi : X \to B$ be a surjective morphism. Assume moreover that for any $0 \leq i \leq r$, $Y_i$ is smooth projective, $X_i$ is flat over a (common) Zariski open subset $B^* \subset B$, $\text{codim}_{X_i}(X_i \setminus X_{i+1}) \geq 2$ and finally there exists a line bundle on $B$ whose restriction to fibers of the projective bundle $q_i'$ is non-trivial. Then for any $b \in B^*$

$$\text{Im}(\text{CH}(X) \to \text{CH}(X_b)) = \sum_{i=0}^r \iota_i \text{Im}(q_{i,b}' : \text{CH}(Y_i) \to \text{CH}(X_{i,b})), $$

where $X_b$ (resp. $X_{i,b}$) is the fiber of $X$ (resp. the Zariski closure of $X_i \setminus X_{i+1}$) over $b$, $\iota_i : X_{i,b} \hookrightarrow X_b$ is the natural inclusion and $q_{i,b}'$ is the restriction of $q_i$ to $X_{i,b}$.
Proof. Since the $X_i$’s are flat over $B^0$, by base-change, the right-hand side is clearly contained in the left-hand side. We use induction on $r$ to prove the other inclusion. For any $z \in \text{CH}(X)$, the projective bundle formula shows that

$$j^*(z) = \sum_{k \geq 0} q''_0(z_k) \cdot \xi^k,$$

for some cycles $z_k \in \text{CH}(Y_0 \setminus Y_1)$ where $j : X \setminus X_1 \hookrightarrow X$ is the open immersion and $\xi = c_1(O_{\mathcal{I}}(1))$. By hypothesis, $\xi = j^\ast \pi^\ast(h) + q''_0(\alpha)$, where $h$ is a divisor on $B$ and $\alpha \in \text{CH}(Y_0 \setminus Y_1)$. We extend $z_k$ and $\alpha$ to $Y_0$, keeping the same notation for the classes on $Y_0$. Therefore

$$z - \sum_k q''_0(z_k) \cdot (\pi^\ast(h) - q''_0(\alpha))^k \in \text{Ker}(j^\ast).$$

By the localization sequence, there exists $\gamma \in \text{CH}(X_1)$, such that

$$z = \sum_k q''_0(z_k) \cdot (\pi^\ast(h) - q''_0(\alpha))^k + \iota(\gamma),$$

where $\iota : X_1 \hookrightarrow X$ is the natural inclusion.

Noting that the restriction of $\pi^\ast(h)$ to $X_b$ vanishes, we have that

$$z|_{X_b} \in \text{Im}(q'' : \text{CH}(Y) \to \text{CH}(X_b)) + \text{Im}(\iota : \text{CH}(X_1 \to X)|_{X_b}),$$

where the second term is $t_1, \text{Im}(\text{CH}(X_1) \to \text{CH}(X_1,b))$ by flat base-change. Observing that $q_1 : X_1 \to Y_1$ is again a stratified projective bundle verifying all the conditions, the induction hypothesis allows us to conclude. □

5.2. Cubes and Hilbert cubes of complete intersection K3 surfaces. We prove Theorem 1.4 for cubes and Hilbert cubes in this subsection. Notation is as in §4.

The geometry is quite close\footnote{In fact, complete intersection K3 surfaces are special cases of Calabi–Yau complete intersections considered in [14] and so all results in loc.cit. apply.} to the one considered in [14], in particular, we will study collinear triples in the projective space $\mathbb{P}$. For three points in $\mathbb{P}$ there are four types of relative positions: non-collinear, collinear and distinct, two coincide but not with the third, all coincide. As a result, the evaluation map of the relative cube of the universal family

$$q : S \times_B S \times_B S \to \mathbb{P} \times \mathbb{P} \times \mathbb{P}$$

is not a projective bundle but is a stratified projective bundle (Definition 5.1) with the following stratification:

\begin{align*}
S = \delta_{S/B} \xrightarrow{c} \Delta_{12} \cup \Delta_{13} \cup \Delta_{23} \xrightarrow{c} \Delta_{12} \cup \Delta_{13} \cup \Delta_{23} \cup \Delta_3 \xrightarrow{c} S \times_B S \times_B S & \xrightarrow{\pi_3} B \\
P = \delta_p \xrightarrow{c} \Delta_{12} \cup \Delta_{13} \cup \Delta_{23} \xrightarrow{c} \Delta_3 \xrightarrow{c} \mathbb{P} \times \mathbb{P} \times \mathbb{P}
\end{align*}

where in the first row, $\Delta_{i,j} : S \times_B S \hookrightarrow S \times_B S \times_B S$ are three big (relative) diagonals, $\Delta$ is the Zariski closure of

$$\Delta : = \{(x,y,z) \in S \times_B S \times_B S \mid x, y, z \text{ collinear and distinct}\};$$

in the second row, $\Delta_{i,j} : P \times P \hookrightarrow P \times P \times P$ are three big diagonals and

$$J := \{(x,y,z) \in P \times P \times P \mid x, y, z \text{ collinear}\}.$$
Proposition 5.3. We have for any $b \in B^0$,
\[
\operatorname{Im}(\mathrm{CH}(S \times_B S \times_B S) \to \mathrm{CH}(S_b \times S_b \times S_b)) = \operatorname{Im}(\mathrm{CH}(P \times P \times P) \to \mathrm{CH}(S_b \times S_b \times S_b)) + \sum_{1 \leq i < j \leq 3} \Delta_{i,j} \operatorname{Im}(\mathrm{CH}(P \times P) \to \mathrm{CH}(S_b \times S_b)) + \delta \operatorname{Im}(\mathrm{CH}(P) \to \mathrm{CH}(S_b)),
\]
where $\Delta_{i,j} : S^3_b \hookrightarrow S^3_b$ are the inclusions of big diagonals and $\delta : S_b \hookrightarrow S^3_b$ is the inclusion of the small diagonal.

Proof. It is straight-forward to check that \cite{7} indeed stratifies $q$ into projective bundles and the codimension of $I$ in $S \times_B S \times_B S$ is $\dim(P) - 1$ (cf. \cite{14} Lemma 1.2) which is $\geq 2$. Moreover, it is clear that $\pi_b^*\mathcal{O}_B(1)$ restricts to the relative ample tautological line bundle on fibers of all projective bundles. All assumptions of Proposition 5.2 being satisfied, it implies that for any $b \in B^0$,
\[
\operatorname{Im}(\mathrm{CH}(S \times_B S \times_B S) \to \mathrm{CH}(S_b \times S_b \times S_b)) = \operatorname{Im}(\mathrm{CH}(P \times P \times P) \to \mathrm{CH}(S_b \times S_b \times S_b)) + \sum_{1 \leq i < j \leq 3} \Delta_{i,j} \operatorname{Im}(\mathrm{CH}(P \times P) \to \mathrm{CH}(S_b \times S_b)) + \delta \operatorname{Im}(\mathrm{CH}(P) \to \mathrm{CH}(S_b)),
\]
where $\iota : I_b \hookrightarrow S^3_b$ is the inclusion of the Zariski closure of the locus of collinear and distinct triples. We only have to show that the second term on the right-hand side is redundant. Indeed, for any $b \in B^0$, consider the cartesian square
\[
\begin{array}{ccc}
\Delta_{12} \cup \Delta_{13} \cup \Delta_{23} \cup I_b & \xrightarrow{\iota} & S_b \times S_b \times S_b \\
\downarrow & & \downarrow \\
J & \xrightarrow{\square} & P \times P \times P
\end{array}
\]
Here the intersection is transversal along $I_b \setminus \Delta_{i,j}$ (without excess intersection) and $\operatorname{codim}_{S^3_b} I_b = \operatorname{codim}_{P^3} J = \dim P - 1$, while along $\Delta_{i,j}$ the intersection has excess dimension $\dim P - 3$ (cf. \cite{14} Lemma 1.2]) with excess normal bundle $\mathcal{O}(1)_{\mathcal{O}(1)}(1)$. The excess intersection class on $\Delta_{i,j} = S_b \times S_b$ is therefore a polynomial in $h_1$ and $h_2$ with $h_i := \pi^*_i(\mathcal{O}(1)|_{S_b})$, hence is the pull-back of an element in $\mathrm{CH}(P \times P)$. As a result, by the excess intersection formula (cf. \cite{18} §6.3]) applied to the above cartesian square, any element in the second term $\iota_* \operatorname{Im}(\mathrm{CH}(J) \to \mathrm{CH}(I_b))$, up to an element in the third term $\sum_{1 \leq i < j \leq 3} \Delta_{i,j} \operatorname{Im}(\mathrm{CH}(P \times P) \to \mathrm{CH}(S_b \times S_b))$, is an element in the first term $\iota_* \operatorname{Im}(\mathrm{CH}(P \times P \times P) \to \mathrm{CH}(S_b \times S_b \times S_b))$, thus is redundant. \hfill \square

We are now ready to prove the remaining cases of Theorem 1.4:

Proof of Theorem 1.4 for relative cubes. Denote by $h = c_1(\mathcal{O}_P(1)|_{S_b})$ and $h_i := \pi^*_i(h)$. Thanks to Proposition 5.3, for any $z \in \mathrm{CH}(S \times_B S \times_B S)$ and any $b \in B^0$, the restriction $z|_{S_b \times S_b \times S_b}$ is a polynomial in $h_1, h_2, h_3, \Delta_{12}, \Delta_{13}, \Delta_{23}$ (and $\delta = \Delta_{12}\Delta_{23}$). We can conclude by the $m = 3$ case of Voisin’s \cite{41} Proposition 2.2], where the essential point is the decomposition of the small diagonal due to Beauville–Voisin \cite{7} Proposition 3.2]. \hfill \square

\footnote{So there is no excess intersection in the case of quartic surfaces.}
Proof of Theorem 1.4 for relative Hilbert cubes. To simplify the notation, we denote by $S^{[m]} := \text{Hilb}^m(S)$ and similarly $S^{[m]/B} := \text{Hilb}^m_B S$. Let us first recall the result of de Cataldo–Migliorini [11] in the special case of Chow groups of Hilbert cubes of surfaces: for any surface $S$, denote by $\rho : S^{[3]} \to S^{(3)}$ the Hilbert-Chow morphism which sends a 0-dimensional subscheme to its support 0-cycle. We have the incidence subvarieties

$$U := \{(z, x_1, x_2, x_3) \in S^{[3]} \times S^3 \mid \rho(z) = x_1 + x_2 + x_3\};$$
$$V := \{(z, x_1, x_2) \in S^{[3]} \times S^2 \mid \rho(z) = 2x_1 + x_2\};$$
$$W := \{(z, x) \in S^{[3]} \times S \mid \rho(z) = 3x\};$$

and the main result of [11] says that they together induce an injective morphism

$$(U_*, V_*, W_*) : \text{CH}(S^{[3]}) \hookrightarrow \text{CH}(S^3) \oplus \text{CH}(S^2) \oplus \text{CH}(S).$$

Note that the above correspondences have natural family counterparts, denoted by $U_*, V_*, W_*$. Let $z \in \text{CH}(S^{[3]/B})$ be such that the cohomology class of $z|_{S^3_B}$ vanishes. By the above injectivity, it is enough to show that for any $b \in B^*$, $U_*(z|_{S^3_b}), V_*(z|_{S^3_b})$ and $W_*(z|_{S^3_b})$ are zero. To this end, observe that $U_*(z|_{S^3_b}) = U_*(z)|_{S^3_b}$ is the restriction of a cycle of the total family $S \times_B S \times_B S$ with trivial cohomology class, hence is zero by the relative cube case of Theorem 1.4 just proven. Similarly, the vanishing of $V_*(z|_{S^3_b})$ and $W_*(z|_{S^3_b})$ follow from the relative square case proven in §4 and [33] respectively. Finally, the proof of the case of $S \times_B S^{[2]/B}$ is similar (in fact, easier) by using the motivic decomposition for Hilbert squares.

5.3. Beyond complete intersection K3 surfaces. The techniques we utilized above in order to prove Theorem 1.4 for (Hilbert) squares and cubes of complete intersection K3 surfaces can also be employed to attack the Generalized Franchetta Conjecture 1.3 for families of K3 surfaces for which Mukai models are available. In this subsection, we give a sufficient condition for the conjecture to hold for Hilbert schemes of K3 surfaces in a certain range.

Recall that for a natural number $g$, we say that the Mukai model for K3 surfaces of genus $g$ exists, if there exist an ambient homogeneous space $G = G_g$ (often a Grassmannian) and a globally generated homogeneous vector bundle $E = E_g$ on $G$, such that the zero locus of a general section of $E$ gives a general K3 surface of genus $g$. For the available constructions of Mukai models and the corresponding $G$ and $E$, we refer to [13] as well as the original sources [26], [27], [28], [29].

The crucial condition for our techniques to work is the following:

**Definition 5.4.** For an $r \in \mathbb{N}^*$, we say that the Mukai model $(G, E)$ satisfies the condition $(\star_r)$ if

$$(\star_r) : \text{for any } x_1, \cdots, x_r \text{ distinct points of } G, \text{ the following evaluation map is surjective}$$

$$H^0(G, E) \to \bigoplus_{i=1}^r E_{x_i}.$$  

Or equivalently, $H^0(G, E \otimes I_{x_1} \otimes \cdots \otimes I_{x_r})$ is of codimension $r \cdot \text{rank}(E)$ in $H^0(G, E)$. Clearly, $(\star_r)$ implies $(\star_k)$ for all $k < r$. 

Proposition 5.5. Notation is as before. Fix a genus \( g \) for which the Mukai model exists. Assume Condition \((\star_r)\) is satisfied. Then for any \( b \in B^\circ \),

\[
\text{Im} \left( \text{CH}(S^{r/B}) \to \text{CH}(S'_b) \right) = R(S'_b),
\]

where the tautological ring \( R(S') \) is the subring of the (rational) Chow ring \( \text{CH}(S') \) generated by big diagonals \( \Delta_{i,j} \) (\( 1 \leq i < j \leq r \)), polarization classes \( g_i := \text{pr}^*_i(g) \) and Beauville–Voisin classes \( o_i := \text{pr}^*_i(o_S) \) (\( 1 \leq i \leq r \)).

Proof. The proof is to rephrase every step of §5.2 in the general setting. We proceed by induction on \( r \). Consider the evaluation map \( q : S'^{r/B} \to G' \), which is a stratified projective bundle (Definition 5.1) with the stratification on \( G' \) given by the different types of incidence relations for \( r \) points of \( G \):

\[
\begin{align*}
X_n = S' & \longrightarrow \cdots \longrightarrow X_1 \underset{q_1=p}{\longrightarrow} X_0 = S^{r/B} \longrightarrow B \\
Y_n = G' & \longrightarrow \cdots \longrightarrow Y_1 \underset{q_0=q}{\longrightarrow} Y_0 = G'
\end{align*}
\]

By Proposition 5.2 for any \( b \in B^\circ \),

\[
\text{Im} \left( \text{CH}(S^{r/B}) \to \text{CH}(S'_b) \right) = \sum_{i=0}^{n} i_i^* \text{Im} \left( \text{CH}(Y_i) \to \text{CH}(X'_i) \right),
\]

where \( X'_i \) is the Zariski closure of \( X_i \setminus X_{i+1} \). Let us show that each term of (9) is in the tautological ring \( R(S'_b) \) by ascending order for \( 0 \leq i \leq n \):

- If \( i = 0 \), since the Chow ring of \( G \) satisfies the K"unneth formula, we only need to show that

\[
\text{Im} \left( \text{CH}(G) \to \text{CH}(S_b) \right) \subset R(S_b).
\]

However, since \( \text{CH}(G) \) is generated by the Chern classes of its tautological subbundle, so it is enough to check that \( c_1(G)|_{S_b} \) and \( c_2(G)|_{S_b} \in R(S_b) \). The first one is precisely the polarization class and the second one follows from a direct computation using the short exact sequence

\[
0 \to T_{S_b} \to T_G|_{S_b} \to E|_{S_b} \to 0,
\]

together with the fact that \( c_2(S_b) = 24o_{S_b} \) (8).

- If a general point of \( Y_i \) is parameterizing \( r \) points of \( G \) where at least two of them coincide, then the contribution of the \( i \)-th term of (9) factors through \( R(S'_b) \) by the induction hypothesis, hence is contained in \( R(S'_b) \).

- If a general point of \( Y_i \) is parameterizing \( r \) different points of \( G \), then the hypothesis \((\star_r)\) means precisely that any \( r \) different points of \( G \) impose independent conditions on \( B \), each of codimension \( \text{rank}(E) \). Therefore, \( X'_i \), the Zariski closure of \( X_i \setminus X_{i+1} \), has the same codimension in \( X_{i-1} \) as \( \text{codim}_{Y_i}(Y_i) \). The excess intersection formula (18 §6.3) applied to the cartesian diagram

\[
\begin{align*}
X_i = X_{i+1} \cup X'_i & \longrightarrow X_{i-1} \\
\downarrow \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \ quasi
tells us that modulo the \((i + 1)\)-th term of (9), the contribution of the \(i\)-th term is contained in the \((i - 1)\)-th term.

\[\square\]

**Theorem 5.6.** Let \(g \in \mathbb{N}^*\) such that the Mukai model exists for K3 surfaces of genus \(g\). Assume the Mukai model satisfies the condition \((\star_1)\). If moreover, the cycle class map restricted to the tautological ring \(R(S^g)\) is injective for any K3 surface \(S\) of genus \(g\), then the Generalized Franchetta Conjecture 1.3 holds for \(S^{[r_1]/B} \times_B \cdots \times_B S^{[r_m]/B}\), for any \(r_1, \ldots, r_m\) whose sum \(\leq r\), where \(S \to B\) is the universal family of K3 surfaces of genus \(g\).

**Proof.** The case of relative powers \(S^{k/B}\), for any \(k \leq r\) is a direct consequence of Proposition 5.5 and the hypothesis on the injectivity of the cycle class map on the tautological ring. For other cases, we use de Cataldo–Migliorini’s result [11] for Chow motives of Hilbert schemes of surfaces to reduce to the cases of \(S^{k/B}\) for all \(1 \leq k \leq r\). \[\square\]

We apply Theorem 5.6 to some Mukai models to get concrete unconditional results:

**Proof of Theorem 1.5.** To use Theorem 5.6, we proceed by a case-by-case analysis of the positivity of the homogeneous bundle in the Mukai model. See Mukai’s series of papers [26], [27], [28], [29] for more information on the geometry of these models.

- K3 surfaces of genus \(g = 2\) are smooth degree 6 hypersurfaces in the weighted projective space \(\mathbb{P} := \mathbb{P}(1, 1, 1, 3)\). The Mukai model for this family is thus \((G, E) = (\mathbb{P}, \mathcal{O}(6))\). Note that the K3 surfaces in this family all avoid the singular point \(O = [0, 0, 0, 1]\). Let us check the condition \((\star_3)\), i.e., that the evaluation map

\[H^0(\mathbb{P}, \mathcal{O}(6)) \to \bigoplus_{i=1}^3 C_{x_i}\]

is surjective for distinct \(x_1, x_2, x_3 \neq O\), where \(C_x\) denotes the fiber of \(\mathcal{O}(6)\) at \(x\). It is easy to see that \(\mathbb{P}(1, 1, 1, 3)\) is isomorphic to the projective cone over the third Veronese embedding of \(\mathbb{P}^2\) (cf. [12]) and \(O\) is the vertex. By upper-semicontinuity, it is enough to treat the most degenerate case for three distinct points of \(\mathbb{P} \setminus \{O\}\), which is when they lie in the same ruling of the projective cone. In this case, as the restriction of \(\mathcal{O}(6)\) to the ruling is \(\mathcal{O}(2)\), the condition \((\star_3)\) follows from the surjections:

\[H^0(\mathbb{P}, \mathcal{O}(6)) \to H^0(\mathbb{P}^1, \mathcal{O}_{\mathbb{P}^1}(2)) \to \bigoplus_{i=1}^3 C_{x_i},\]

where \(\mathbb{P}^1\) is the ruling which contains \(x_i\)’s. To conclude, by Theorem 5.6, we only need to know the injectivity of the cycle class map restricted to the tautological ring \(R(S^3)\), which is covered by Voisin’s [41, Proposition 2.2].

- For quartic surfaces \((g = 3)\), let us first show that \((\mathbb{P}^3, \mathcal{O}(4))\) satisfies \((\star_5)\), i.e., that the evaluation map

\[H^0(\mathbb{P}^3, \mathcal{O}(4)) \to \bigoplus_{i=1}^5 C_{x_i}\]

is surjective for distinct \(x_i\)’s. Again, it is enough to treat the most degenerate cases, namely:

---

8Equivalently, these K3 surfaces are also double covers of \(\mathbb{P}^2\) ramified along smooth sextic curves.
– when \(x_1, \ldots, x_5\) are collinear, then this follows from the surjectivity of the restriction and the evaluation
\[
H^0(P^3, \mathcal{O}(4)) \to H^0(P^1, \mathcal{O}(4)) \to \bigoplus_{i=1}^5 C_{x_i},
\]
where \(P^1\) is the line containing these points.

– when \(x_1, \ldots, x_5\) are in a conic \(C\). Then the Koszul resolution provides an exact sequence
\[
0 \to \mathcal{O}_{P^3}(-3) \to \mathcal{O}_{P^3}(-1) \oplus \mathcal{O}_{P^3}(-2) \to \mathcal{O}_{P^3} \to \mathcal{O}_C \to 0,
\]
which allows us to see that the restriction map \(H^0(P^3, \mathcal{O}(4)) \to H^0(C, \mathcal{O}_C(8))\) is surjective.

Since \(H^0(C, \mathcal{O}_C(8)) \to \bigoplus_{i=1}^5 C_{x_i}\) is clearly surjective, we are done.

The condition (⋆) is proven. By Voisin [11, Proposition 2.2], the cycle class map restricted to the tautological ring \(R(S^3)\) is injective for a quartic K3 surface \(S\). Now both assumptions of Theorem 5.6 being satisfied, we can conclude.

- For \(g = 6\), the Mukai model is \((G, E) = (\text{Gr}(2, 5), \mathcal{O}(1)^{\oplus 3} \oplus \mathcal{O}(2))\), where \(\mathcal{O}(1)\) is the Plücker line bundle. It is clear that the condition (⋆) is equivalent to the surjectivity of
\[
H^0(G, \mathcal{O}(1)) \to C_{x_1} \oplus C_{x_2}
\]
for any two distinct points \(x_1, x_2 \in G\). However, the last condition follows from the very ampleness of the Plücker line bundle \(\mathcal{O}(1)\).

- For \(g = 7\), the Mukai model is \((G, E) = (\text{OGr}(5, 10), U^{\oplus 8})\), where \(\text{OGr}(5, 10)\) is the orthogonal Grassmannian parameterizing isotropic subspaces of dimension 5 in a vector space of dimension 10 equipped with a non-degenerate quadratic form and \(U\) is a line bundle corresponding to the half spinor representation. The proof is similar to the previous case: one uses the very ampleness of \(U\).

- For \(g = 8\), the Mukai model is \((G, E) = (\text{Gr}(2, 6), \mathcal{O}(1)^{\oplus 6})\), where \(\mathcal{O}(1)\) is the Plücker line bundle. The proof goes as for \(g = 6\) by the very ampleness of the Plücker line bundle.

- For \(g = 9\), the Mukai model is \((G, E) = (\text{LGr}(3, 6), \mathcal{O}(1)^{\oplus 4})\), where \(\text{LGr}(3, 6)\) is the symplectic Grassmannian parameterizing Lagrangian subspaces in a 6-dimensional vector space equipped with a symplectic form and \(\mathcal{O}(1)\) is the restriction of the Plücker line bundle of \(\text{Gr}(3, 6)\). The proof goes as before: one uses the very ampleness of \(\mathcal{O}(1)\).

- For \(g = 10\), the Mukai model is \((G, E) = (\text{Gr}(2/P, \mathcal{O}(1)^{\oplus 3})\), where \(G\) is the 5-dimensional quotient of the simply-connected semi-simple algebraic group of type \(G_2\) by a maximal parabolic subgroup \(P\) and \(\mathcal{O}(1)\) is the line bundle associated to the adjoint representation of \(G_2\); in other words, \(G = \text{Gr}(2/P) \hookrightarrow \mathbb{P}(\mathcal{N})\). Again, we can conclude by the very ampleness of \(\mathcal{O}(1)\).

- For \(g = 12\), we use a slight variant of the above argument. Indeed, the general K3 surface of genus 12 can be constructed as an anti-canonical section in a smooth prime Fano threefold \(X\) of genus 12 (cf. [11, Section 3.1]). The Fano threefold \(X\) has very ample anti-canonical bundle, and \(H^2(X, \mathcal{Q}) = 0\) ([11, Corollary 4.3.5]) so that \(X\) has trivial Chow groups\(^9\) (this Fano threefold \(X\) is the variety denoted by \(X_{22} \subset \mathbb{P}^3\) in [11] Propositions 4.1.11 and 4.1.12]; actually \(X\) is an intersection of quadrics). We now consider a variant of Theorem 5.6 replacing \(G\) by \(X\) and \(E\) by \(-K_X\). The very ampleness of \(-K_X\) ensures that condition (⋆) holds. As \(X\) has trivial Chow groups, there is a Chow–Künneth formula for products of \(X\), and so one is reduced to the statement for the K3 surface \(S_0\), which is [33].

\(^9\)Following Voisin [42], we say a smooth projective variety has \(trivial\ \text{Chow groups}\) if the cycle map \(\text{cl}^i : \text{CH}^i(X)_{\mathbb{Q}} \to H^{2i}(X, \mathbb{Q})\) is injective for any \(i\).
Remark 5.7 (Limit of our method). Given a Mukai model \((G, E)\),

- the global generation of \(E\) corresponds to condition \((\ast_1)\), which explains the essential reason why one can prove the Generalized Franchetta Conjecture for K3 surfaces with a Mukai model in \[33\].

- For K3 surfaces of genus 2, \(G = \mathbb{P}(1, 1, 1, 3)\) and \(E = O(6)\), the condition \((\ast_4)\) is not satisfied: it is violated by three distinct points lying on the same ruling, away from the singular point.

- For the quartic K3 surfaces, \(G = \mathbb{P}^3\) and \(E = O(4)\), the condition \((\ast_5)\) is not satisfied: it is violated by six collinear distinct points. Similarly, for the other two families of complete intersection K3 surfaces (genus 4 and 5), \((\ast_4)\) is violated by four collinear distinct points.

- For K3 surfaces of genus 6 and 8, whose Mukai model is \((G, E) = (\text{Gr}(2, 5), O(1)^{\otimes 3} \oplus O(2))\) and \((\text{Gr}(2, 6), O(1)^{\otimes 6})\) respectively, the condition \((\ast_3)\) is not satisfied. Indeed, it is equivalent to the surjectivity of \(H^0(G, O(1)) \to C_{x_1} \oplus C_{x_2} \oplus C_{x_3}\), which is violated by three distinct collinear points of \(G\).

- For K3 surfaces of genus 13 and 20, the Mukai models are respectively

\[(G, E) = \left(\text{Gr}(3, 7), (\wedge^2 S^\vee)^{\otimes 2} \oplus \wedge^3 Q\right)\text{ and } \left(\text{Gr}(4, 9), (\wedge^2 S^\vee)^{\otimes 3}\right).

where \(S\) is the tautological sub-bundle and \(Q\) is the tautological quotient bundle. We claim that none of them verifies the condition \((\ast_2)\). For example, in the genus 13 case, the condition \((\ast_2)\) is equivalent to the surjectivities of the following two evaluation maps

\[H^0(G, \wedge^2 S^\vee) \to \wedge^2 S^\vee_x \oplus \wedge^2 S^\vee_y,\]

\[H^0(G, \wedge^2 Q) \to \wedge^2 Q_x \oplus \wedge^2 Q_y,\]

for any \(x \neq y \in G\), which, by Bott theorem, amount to say that for any two different 3-dimensional subspaces \(W_1, W_2\) in a 7-dimensional vector space \(V\), the natural maps

\[\wedge^2 V^\vee \to \wedge^2(W^\vee_1) \oplus \wedge^2(W^\vee_2)\]

\[\wedge^2 V \to \wedge^2(V/W_1) \oplus \wedge^2(V/W_2)\]

are surjective. It is not true when \(\dim W_1 \cap W_2 \geq 2\). The case of genus 20 is similar.

- For K3 surfaces of genus 18, the Mukai model is \((G, E) = (O\text{Gr}(3, 9), U^{\otimes 5})\), where \(U\) is the rank 2 vector bundle associated to the representation \(V\) associated to the fourth dominant weight \(\omega_4 = \frac{1}{2}(\alpha_1 + 2\alpha_2 + 3\alpha_3 + 4\alpha_4)\), of the (semi-simple part of the) maximal parabolic group \(P\). We claim that \((\ast_2)\) does not hold, i.e., there exist two different points \(x, y \in G\) such that \(H^0(G, U) \to U_x \oplus U_y\) is not surjective. Let \(x = P/P\) and \(y = wP/P\) where \(w = s_{\alpha_3}\), as an element in the Weyl group \(W\), is the reflection with respect to the third simple root. Clearly, \(w\) does not belong to the Weyl group \(P\), which is generated by \(s_{\alpha_1}, s_{\alpha_2}, s_{\alpha_3}\). A direct computation shows that the representation \(H^0(G, U)\) has multiplicity one for all weights. On the other hand, \(\omega_4\) is a common weight for \(V\) and its conjugate by \(w\) (since \(w.\omega_4 = \omega_4\)). Hence \(H^0(G, U) \to U_x \oplus U_y\) cannot be surjective.

- If one wants to follow the same strategy of this paper to attack the Generalized Franchetta Conjecture \[1.3\] for (Hilbert) powers beyond the range stated in Theorem \[1.4\] and Theorem \[1.5\] one has to deal with some essentially new universal cycle, which may not belong to the tautological ring, or rather, the tautological ring should be enlarged to include some more incidence classes from projective geometry than just the polarization class.

\[\text{We thank Nicolas Ressayre for his kind help on the proof.}\]
Nevertheless, the injectivity of the cycle class map restricted to the enlarged tautological ring is a consequence of the general Bloch-Beilinson conjecture over number fields.

5.4. Applications towards the Beauville–Voisin conjecture. Let us now turn to the consequences of our results in the direction of the Beauville–Voisin conjecture (and its refined version Conjecture 2.4):

Proof of Corollaries 1.6 and 1.7 and 1.8 The coisotropic subvarieties $E_\mu$, the Lagrangian surfaces $T$ and $U$, and the Lagrangian threefold $I$ of Corollary 1.8 can all be defined over (suitable relative powers of) the universal family, and so these are just special cases of Proposition 2.5 combined with Theorems 1.4 and 1.5. □

One can also prove a version of Corollaries 1.6 and 1.7 and 1.8 for product varieties of arbitrarily high dimension, but the statement is now restricted to 0–cycles and 1–cycles:

Corollary 5.8. Let $X$ be a product

$$X = X_1 \times X_2 \times \cdots \times X_s,$$

where $X_j$ is either a Hilbert square $S^{[2]}$ where $S$ is a K3 surface of genus $g \in \{2, 3, 4, 5, 6, 7, 8, 9, 10, 12\}$, or a Hilbert cube $S^{[3]}$ where $S$ is a degree 6 complete intersection K3, or a Hilbert scheme $S^{[r]}$ where $S$ is a quartic K3 surface and $r \leq 5$. Let $\widetilde{R}(X) \subset CH(X)$ denote the $\mathbb{Q}$-subalgebra generated by (pullbacks of) divisors on $X_j$, the Chern classes $c_i(T_{X_j})$, plus the following coisotropic subvarieties:

- the coisotropic subvarieties $E_\mu$ of [44, 4.1 item 1]);
- the Lagrangian surfaces $T \subset X_j$ constructed in [20, Proposition 4] (if $X_j = S^{[2]}$);
- the surface of bitangents $U \subset X_j$ (if $X_j = S^{[2]}$ and $S$ is a quartic K3 surface);
- the locus $I \subset X_j$ as in Corollary 1.8 (if $X_j = S^{[3]}$ and $S$ is a degree 6 K3 surface).

Then $\widetilde{R}^{2m}(X)$ and $\widetilde{R}^{2m-1}(X)$ inject into cohomology via the cycle class map.

Proof of Corollary 5.8 This uses the fact that the $X_j$ have a multiplicative Chow–Künneth decomposition $\{\pi_{X_j}^k\}$, in the sense of [35, Chapter 8], [36]; see also Appendix A.2. This induces a bigrading of the Chow ring of $X_j$, given by

$$CH^i(X_j)_{(k)} := (\pi_{X_j}^{2i-k}), CH^i(X_j).$$

It is readily seen that the projectors $\pi_{X_j}^k$ are universally defined (i.e., they exist as a relative cycle for the family $X_j \times_X X^\circ_j$). Theorem 5.6 applied to the relative cycle $T - (\pi_{X_j}^k), T$ (where we use the formalism of relative correspondences as in [30, Section 8.1]), thus implies that

$$T \in CH^2(X_j)_{(0)}.$$

Similarly $U \in CH^2(X_j)_{(0)}$ and $I \in CH^3(X_j)_{(0)}$. The same argument also shows that $E_\mu \in CH^*(X_j)_{(0)}$, which is actually true for Hilbert schemes of arbitrary K3 surfaces, cf. [44, Lemma 4.3].

The product $X$ also has a multiplicative Chow–Künneth decomposition, and hence there is a bigrading of the Chow ring $CH(X)$, by [35, Theorem 8.6]. Since divisors and Chern classes of

---

1In this paper, the notation $R(X)$ is reserved for the tautological ring of $X = S^n$ a power of K3 surface, generated by big diagonals and Chern classes.
are also in $\text{CH}(X_j)_{(0)}$, and pullback under any projection $X \to X_j$ preserves the bigrading \cite[Corollary 1.6]{16}, we see that there is an inclusion

$$\tilde{R}(X) \subset \text{CH}(X)_{(0)}.$$ 

The corollary now follows, since it is known that $\text{CH}^i(X)_{(0)}$ injects into cohomology for $i \geq \text{dim}(X) - 1$, see \cite[Introduction]{19}. □

5.5. **Double EPW sextics.** The interested reader will have no trouble finding further applications in the flavour of Corollaries \cite[1.6]{16}, \cite[1.7]{17} and \cite[1.8]{18}. For instance, consider the Hilbert square $X = S^{[2]}$, where $S$ is a generic K3 surface of genus 6. As shown by O’Grady \cite[Section 4]{31}, $X$ is isomorphic to a small resolution $X_A$ of a singular double EPW sextic $X_A$ (notation is as in \cite{31}). Let $\epsilon : X \to X_A$ denote the small resolution, and let $f_A : X_A \to Y_A$ denote the double cover to the associated EPW sextic $Y_A$. The surface $S$ being generic corresponds to the fact that the Lagrangian vector space $A$ is generic (in the precise sense given in \cite[§4]{31}) in the divisor $\Delta \subset \text{LGr}(\wedge^3 V)$ studied in \cite{31}. This construction produces Lagrangian surfaces in $X$: the surface

$$P := \epsilon^{-1}(\text{Sing}(X_A))$$

(which is isomorphic to $\mathbb{P}^2$ since $X_A$ has only one singular point), and the surface

$$\text{Fix} := \epsilon^{-1}(\text{Fix}(\iota)),$$

where $\text{Fix}(\iota)$ denotes the fixed point locus of the (anti–symplectic) covering involution $\iota$ of $X_A$. These Lagrangian surfaces are easily seen to be universally defined. (Indeed, as shown in \cite{31}, there is a stratification

$$\text{Fix} = (f_A \circ \epsilon)^{-1}(Y_A[2]), \quad P = (f_A \circ \epsilon)^{-1}(Y_A[3]).$$

On the other hand (as explained in \cite[Section 3]{31}), there exist family versions $Y[i]$ of the subvarieties $Y_A[i]$ over the base $\Delta$. One can do a base change

$$
\begin{array}{c}
\overline{X}_{B^0} \to \overline{X} \\
\downarrow \quad \downarrow \\
\mathcal{Y}_{B^0} \to \mathcal{Y} \\
\downarrow \quad \downarrow \\
B^0 \to \Delta
\end{array}
$$

where $B^0 \subset B$ is an open such that the rational map $B \to \Delta$ of \cite[Section 4]{31} is defined, and $\overline{X}$ is the tautological family of singular double EPW sextics over $\Delta$. One obtains relative versions of $P$ and $\text{Fix}$ by pulling back $\mathcal{Y}[i]$ under the birational morphism $X_{B^0} \to \overline{X}_{B^0}$.) Thus, applying Theorem 1.5 one obtains the following:

**Corollary 5.9.** Let $X = S^{[2]}$, where $S$ is a generic K3 surface of genus 6. The $\mathbb{Q}$-subalgebra

$$< D_1, D_2, c_i(T_X), P, \text{Fix}, T > \subset \text{CH}(X)$$

injects into cohomology via the cycle class map. (Here $D_1, D_2$ are two divisors generating the Picard group of $X$, and $T$ is the Lagrangian surface of \cite[Proposition 4]{20}.)
5.6. An application to Bloch’s conjecture. Given a quartic K3 surface $S$, Beauville [3] constructed an interesting involution $\iota$ on $X := S^{[2]}$, which generically sends $\{x_1, x_2\}$ to $\{x_3, x_4\}$, where $x_1, \ldots, x_4$ are the four intersection points of the line $\overline{x_1, x_2}$ with $S$. The involution $\iota$ is anti-symplectic. According to the generalized Bloch conjecture (cf. [40, §11.2]), which roughly says that $\text{CH}_0$ is ‘controlled’ by the holomorphic forms, the action of $\iota$ on $\text{CH}_0(X)$ should be id on $\text{Gr}^0 F_\iota \text{CH}_0(X)$ and $\text{Gr}^1 F_\iota \text{CH}_0(X)$ (just as on $H^0(X)$ and $H^{4,0}(X)$) and should be $-\text{id}$ on $\text{Gr}^2 F_\iota \text{CH}_0(X)$ (just as on $H^{2,0}(X)$), where $F$ is the conjectural Bloch–Beilinson filtration. On the other hand, as conjectured in [5] by Beauville and worked out by Shen–Vial in [35] in the case of Hilbert squares of K3 surfaces, we have a canonical splitting of this filtration for $X$, giving a direct sum decomposition:

$$\text{CH}^4(X) = \text{CH}^4(X)_0 \oplus \text{CH}^4(X)_{(2)} \oplus \text{CH}^4(X)_{(4)}.$$ 

Hence the action of $\iota$ on the three summands should be $\text{id}$, $-\text{id}$ and $\text{id}$, respectively. Our results allow us to confirm this expectation.

**Proof of Corollary [1.9]** Let $S^o \to B^o$ be the universal family of smooth quartic K3 surfaces and $X^o \to B^o$ be the relative Hilbert square. As noted above, the bigrading $\text{CH}^*(X)_{(i)}$ is induced by a self–dual multiplicative Chow–Künneth decomposition $\{\pi^i_X\}$ that is universally defined. The anti-symplectic involution $\iota$ can also be defined on the level of the universal family; let us denote $\Gamma_i \in \text{CH}^4(X^o \times_{B^o} X^o)$ the graph of the involution $\iota: X^o \to X^o$.

The relative correspondence

$$\pi^i_X \circ \Gamma_i \circ \pi^j_X \in \text{CH}^4(X^o \times_{B^o} X^o)$$

is fiberwise homologically trivial for $i \neq j$. Theorem [1.5] (ii) for $\text{Hilb}^2_b S \times_{B} \text{Hilb}^2_b S$ implies that

$$\left(\pi^i_X \circ \Gamma_i \circ \pi^j_X\right)|_{X_b \times X_b} = 0 \quad \text{in} \quad \text{CH}^4(X_b \times X_b), \quad \forall i \neq j \quad \forall b \in B^0,$$

i.e., $\Gamma_{b}$ belongs to $\text{CH}^4(X_b \times X_b)_{(0)}$, and thus $\iota_b$ preserves the bigrading $\text{CH}^*(X_b)_{(i)}$.

Next, the fact that $\iota_b$ is anti–symplectic means that for any $b \in B^o$ there exists a divisor $D_b \subset X_b$, and a cycle $\gamma_{b}$ supported on $D_b \times D_b$, such that

$$\left((\Delta_X + \Gamma_i) \circ \pi^2_X\right)|_{X_b \times X_b} = \gamma_{b} \quad \text{in} \quad H^8(X_b \times X_b).$$

Using a Hilbert schemes argument as in [42] Proposition 3.7, the $D_b$ and $\gamma_{b}$ can be spread out, i.e., there exists a divisor $D \subset X$ and a relative cycle $\gamma$ supported on $D \times_{B^o} D$ such that

$$\left((\Delta_X + \Gamma_i) \circ \pi^2_X - \gamma\right)|_{X_b \times X_b} = 0 \quad \text{in} \quad H^8(X_b \times X_b), \quad \forall b \in B^0.$$

Applying Theorem [1.5] once more, we find that

$$\left((\Lambda_X + \Gamma_i) \circ \pi^2_X - \gamma\right)|_{X_b \times X_b} = 0 \quad \text{in} \quad \text{CH}^4(X_b \times X_b), \quad \forall b \in B^0.$$ 

For general $b \in B^0$, the restriction $\gamma|_{X_b \times X_b}$ will be supported on (divisor)$\times$(divisor), and so $\gamma|_{X_b \times X_b}$ will act as $0$ on $\text{CH}^2(X_b)_{(2)}$. It follows that

$$(\iota_b)^* = -\text{id}: \quad \text{CH}^2(X_b)_{(2)} \to \text{CH}^2(X_b)_{(2)} \quad \text{for general} \ b \in B^0.$$

To extend this to all $b \in B^0$, one notes that the above construction can be done with a divisor $D \subset X$ in general position with respect to $X_b$.

The statement for $\text{CH}^4(X_b)_{(2)}$ follows upon taking the transpose of relation (11), and using the relation (10). The remaining statements are proven similarly. □

**Remark 5.10.** Corollary [1.9] was proven in a more convoluted way in [23].
6. Lehn-Lehn-Sorger-van Straten hyper-Kähler eightfolds

In this section we first show Theorem 1.11 and then deduce from it Theorem 1.12.

Keep the same notation as in §3. We still have a correspondence:

However the problem is that \( q \) is no longer a projective bundle: the fiber of \( q \) over a pair of lines \( (l, l') \) is the subspace of cubic fourfolds containing both \( l \) and \( l' \), whose dimension depends therefore on the relative position of \( (l, l') \). To adapt the same strategy to this case, we use similar techniques as in [42, 16] by studying the various strata of the morphism \( q \). There are three possible relative positions between two projective lines in \( \mathbb{P}^5 \): identical, intersect but not identical, not intersect.

On the one hand, for a (general) cubic fourfold \( X \) with Fano variety of lines \( F \), let

\[
I := \{(l, l') \in F \times F \mid l \cap l' \neq \emptyset\}
\]

be the 6-dimensional incidence subvariety of \( F \times F \). The incidence subvariety \( I \) has two natural projections to \( F \) with fiber over \( l \in F \) the surface \( S_l \) parameterizing lines inside \( X \) meeting \( l \). Similarly, we consider the family version of this incidence subvariety inside \( F \times B F \):

\[
I := \{(b, l, l') \in F \times B F \mid l \cap l' \neq \emptyset\} = \{(b, l, l') \in B \times G \times G \mid l, l' \subset X_b \ ; l \cap l' \neq \emptyset\}.
\]

On the other hand, we define \( J := \{(l, l') \in G \times G \mid l \cap l' \neq \emptyset\} \) to be the incidence subvariety of \( G \times G \).

These incidence subvarieties, together with the diagonals, give the stratification for \( q \):

\[
\begin{array}{ccc}
\mathcal{F} &=& \Delta_{\mathcal{F} / B} \quad \xrightarrow{q} \quad \mathcal{F} \times_B \mathcal{F} \quad \xrightarrow{\pi_2} \quad B \\
p && q \\
\downarrow && \downarrow \\
G &=& \Delta_G \quad \xrightarrow{\mathcal{F}} \quad G \times G
\end{array}
\]

where \( q \) is a projective bundle outside of \( I \) and \( q|_F \) is also a projective bundle outside of \( \Delta_{\mathcal{F}} \); in other words, \( q \) is a stratified projective bundle in the sense of Definition 5.1.

Applying Proposition 5.2 to \( q \), we have the following analogue of Lemma 3.1 and Proposition 4.1 in our case:

**Proposition 6.1.** For any \( b \in B \), we have

\[
\text{Im} \ (\text{CH}(\mathcal{F} \times_B \mathcal{F}) \to \text{CH}(F_b \times F_b)) = \text{Im} \ (\text{CH}(G \times G) \to \text{CH}(F_b \times F_b)) + i_! \text{Im} \ (\text{CH}(J) \to \text{CH}(I_b)) + \Delta \text{Im} \ (\text{CH}(G) \to \text{CH}(F_b)),
\]

where \( i : I_b \hookrightarrow F_b \times F_b \) and \( \Delta : F_b \hookrightarrow F_b \times F_b \) are the inclusions.
As the incidence subvariety $J$ is singular along the smaller stratum $\Delta_G$, it is more convenient to work with a natural resolution of singularities. To this end, we define

$$
\tilde{I} := \{(b,x,l,l') \in B \times P^5 \times G \mid l,l' \subset X_b \ ; \ x \in l \cap l'\} ;
$$

$$
\tilde{J} := \{(x,l,l') \in P^5 \times G \mid x \in l \cap l'\} ;
$$

$$
\mathcal{P} := \{(b,x,l) \in B \times P^5 \times G \mid l \subset X_b \ ; \ x \in l\} ;
$$

$$
Q := \{(x,l) \in P^5 \times G \mid x \in l\} ,
$$

where $\tilde{I}$ (resp. $\tilde{J}$) admits a natural birational morphism to $I$ (resp. $J$), which contracts $\mathcal{P}$ (resp. $Q$) to $\mathcal{F}$ (resp. $G$). We summarize the situation in the following diagram whose squares are all cartesian:

Recall that $G = \text{Gr}(P^1, P^5)$, $S$ is the tautological rank-2 sub-bundle, $g := c_1(S''|_F) \in CH^1(F)$ is the Plücker polarization class, and $c := c_2(S'|_F) \in CH^2(F)$. We computed in Lemma 3.2 that $c_2(F) = 5g^2 - 8c$. In $CH(F \times F)$, $g_i := pr_i^*(g)$ and $c_i := pr_i^*(c)$ for $i = 1, 2$.

**Definition 6.2** (Tautological ring of $F \times F$). Let $X$ be a smooth cubic fourfold and $F$ be its Fano variety of lines. We define the tautological ring of $F \times F$, denoted by $R(F \times F)$, to be the $Q$-subalgebra of $CH(F \times F)$ generated by the classes $c_1, c_2, g_1, g_2, \Delta, I$, where $\Delta$ and $I$ are the class in $CH(F \times F)$ of the diagonal $\Delta_F$ and the incidence subvariety $I$ respectively.

**Proposition 6.3.** For any point $b \in B^0$, we have

$$
\text{Im} (CH(F \times F) \to CH(F_b \times F_b)) = R(F_b \times F_b).
$$

**Proof.** To simplify the notation, let us leave out the subscript $b$. Thanks to Proposition 6.1, we only need to deal with the following three cases:

- For $\text{Im} (CH(G \times G) \to CH(F \times F))$, it is enough to observe that $CH(G \times G)$ satisfies the Künneth formula (since the cycle class map $CH(G \times G) \to H(G \times G, Q)$ is an isomorphism).
- For $i$, $\text{Im} (CH(I) \to CH(I))$, consider

$$
\tilde{I} := \{(x,l,l') \in X \times G \times G \mid x \in l \cap l'\} \quad \text{and} \quad \tilde{J} := \{(x,l,l') \in P^5 \times G \times G \mid x \in l \cap l'\}
$$

fitting into the diagram

$$
\begin{array}{ccc}
\tilde{I} & \xrightarrow{\tau} & I \\
\downarrow & & \downarrow \\
\tilde{J} & \xrightarrow{\tau} & J \\
 & & \downarrow \\
 & & G \times G \\
 & & \downarrow \\
& & P^5
\end{array}
$$
Denote by $\tilde{t} = \tau' \circ i$ and $\tilde{j} = \tau \circ j$. Then any cycle in $I$ can be written as $\tau_*(\alpha)$ for some $\alpha \in CH(I)$. Observe that $I$ is a $\mathbb{P}^4 \times \mathbb{P}^4$-bundle over $\mathbb{P}^5$ such that the two relative $O(1)$ on the fibers are given by $\tilde{j}^*(g_1)$ and $\tilde{j}^*(g_2)$, respectively. Therefore $\alpha$ is a linear combination of cycles of the form $\tau^*(h^k)\tilde{\tau}^*(g_1^m g_2^m)$ where $k, l, m \in \mathbb{N}$ and $h = O_{\mathbb{P}^5}(1)$.

$$
\begin{align*}
\tilde{i}_*(\tau^*(h^k)\tilde{\tau}^*(g_1^m g_2^m))|_I &= \tilde{i}_* \circ \tau'_* \left( \tau^*(h^k)\tilde{\tau}^*(g_1^m g_2^m) \right) \\
&= \tilde{i}_* \left( \tau^*(h^k)\tilde{\tau}^*(g_1^m g_2^m) \right) \\
&= \tilde{g}_1^m g_2^m \cdot \tilde{i}_*(\tau^*(h^k)|_I) \\
&= \tilde{g}_1^m g_2^m \cdot \Gamma_{\tilde{h}_k}
\end{align*}
$$

where $\Gamma_{\tilde{h}_k}$, defined in [35, Appendix A] is the cycle of $F \times F$ represented by the subvariety $\{(l, l') \in F \times F \mid \exists x \in H_1 \cap \cdots \cap H_k \text{ such that } x \in I \cap l' \}$, where $H_1, \ldots, H_k$ are $k$ general hyperplanes in $\mathbb{P}^5$. It is proven in [35, Appendix A] that when $k \geq 1$, $\Gamma_{\tilde{h}_k}$ is actually a polynomial of $c_1, c_2, g_1, g_2$, while $\Gamma_{\tilde{h}_1} = I$.

- For $\Delta, \text{Im} (CH(G) \to CH(F))$, let us remark that for any $\alpha \in CH(F)$, we have $\Delta_c(\alpha) = \Delta \cdot \text{pr}_1^*(\alpha)$. Thus it suffices to see that $\text{Im} (CH(G) \to CH(F))$ is generated by $g$ and $c$.

$\square$

Consequently, in order to prove Theorem 1.11 we need to study the injectivity of the cycle class map restricted to the tautological ring $R(F \times F)$.

**Proposition 6.4.** Let $X$ be a smooth cubic fourfold and let $F$ be its Fano variety of lines. Then the cycle class map restricted to the tautological ring $R^*(F \times F)$ is injective.

**Proof.** It suffices to show the proposition for general cubic fourfolds, in which case

$$
c_1: R(F \times F) \to Hdg^2(F \times F)_Q
$$

is surjective. Let us show it is injective.

Firstly, it is not hard to count the dimensions of the spaces of Hodge classes:

<table>
<thead>
<tr>
<th>$i$</th>
<th>$0$</th>
<th>$1$</th>
<th>$2$</th>
<th>$3$</th>
<th>$4$</th>
<th>$5$</th>
<th>$6$</th>
<th>$7$</th>
<th>$8$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\dim Hdg^{2i}$</td>
<td>$1$</td>
<td>$2$</td>
<td>$6$</td>
<td>$12$</td>
<td>$18$</td>
<td>$6$</td>
<td>$2$</td>
<td>$1$</td>
<td></td>
</tr>
</tbody>
</table>

It is enough to show that the $R^*(F \times F)$ have the same dimensions.

The following relations in $R^*(F \times F)$ are at our disposal.

(i) $g_1 \cdot \Delta = g_2 \cdot \Delta; c_1 \cdot \Delta = c_2 \cdot \Delta$.

(ii) For $i = 1, 2$, we have $12g_ic_i = 5g_i^3 + 4c_i^2 = g_i^4$.

(iii) Voisin’s relation [41][12]:

$\Gamma_2^2 = 2\Delta + I \cdot (g_1^2 + g_1g_2 + g_2^2) + \Gamma_2(g_1, g_2, c_1, c_2),$

where $\Gamma_2$ is a polynomial of weighted degree 4.

(iv) In [35, Proposition 17.5], one finds

$$
\Delta \cdot I = 6c_1\Delta - 3g_1^2\Delta.
$$

[12]The coefficients are made precise by [35, Proposition 17.4].
(v) In [35, Lemma 17.6], there is a polynomial $P$ of weighted degree 4 such that
\[ c_1 \cdot I = P(g_1, g_2, c_1, c_2); \]
\[ c_2 \cdot I = P(g_2, g_1, c_2, c_1). \]

Using these relations, we get easily for each degree a list of generators (as vector-spaces):

- $R^0 = \langle 1 \rangle$;
- $R^1 = \langle g_1, g_2 \rangle$;
- $R^2 = \langle g_1^2, g_1 g_2, g_2^2, c_1, c_2, I \rangle$;
- $R^3 = \langle g_1^3, g_1^2 g_2, g_1 g_2^2, g_2^3, 2!; g_1 c_2, g_2 c_1, g_1 I, g_2 I \rangle$;
- $R^4 = \langle g_1^4, g_1^3 g_2, g_1^2 g_2^2, g_1 g_2^3, g_2^4, c_1^2, c_1 c_2, g_1^2 I, g_2^2 I, g_1 g_2 I, g_1 I, g_2 I, \Delta \rangle$;
- $R^5 = \langle g_1^5, g_1^4 g_2, g_1^3 g_2^2, g_1^2 g_2^3, g_1 g_2^4, g_2^5, c_1^3, c_1^2 c_2, g_1^3 g_2, g_2^3 c_1, g_1^2 g_2^2, g_1 g_2^2 I, g_2 I, \Delta \rangle$;
- $R^6 = \langle g_1^6, g_1^5 g_2, g_1^4 g_2^2, g_1^3 g_2^3, g_1^2 g_2^4, g_1 g_2^5, g_2^6, c_1^4, c_1^3 c_2, g_1^4 g_2, g_2^4 c_1, g_1^3 g_2^2, g_1 g_2^2 I, g_2 I, \Delta \rangle$;
- $R^7 = \langle g_1^7, g_1^6 g_2, g_1^5 g_2^2, g_1^4 g_2^3, g_1^3 g_2^4, g_1^2 g_2^5, g_1 g_2^6, g_2^7, c_1^5, c_1^4 c_2, g_1^5 g_2, g_2^5 c_1, g_1^4 g_2^2, g_1^3 g_2^2, g_1^2 g_2 I, g_2 I, \Delta \rangle$;
- $R^8 = \langle g_1^8, g_1^7 g_2, g_1^6 g_2^2, g_1^5 g_2^3, g_1^4 g_2^4, g_1^3 g_2^5, g_1^2 g_2^6, g_1 g_2^7, g_2^8 \rangle$.

Observe that we have the same number of generators as the dimension of $Hd^2$ for $i \neq 5$ or 6. Therefore the cycle class map $R^i(F \times F) \to H^{2i}(F \times F, \mathbb{Q})$ is injective for $i = 0, 1, 2, 3, 4, 7, 8$.

(vi) As for $i = 5$ (resp. $i = 6$), we use the following (new) tautological relation established in the Appendix Theorem A.1:
\[ 6\Delta_i(g) + g_1 g_2 (g_1 + g_2) \cdot I = Q(g_1, g_2, c_1, c_2), \]
where $Q$ is a polynomial.

Therefore the generator $g_1 \Delta = \Delta_i(g)$ (resp. $g_1^2 \Delta$) is redundant, hence $R^i(F \times F) \to H^{2i}(F \times F)$ is also injective in these two degrees. \qed

Remark 6.5. As a manifestation of the same principle as in [5,3] the extra difficulty encountered here (excess dimension of $I$, the new tautological relation etc.) can be traced back to the lack of positivity of the vector bundle $E = \text{Sym}^3 S^\vee$ on $G = \text{Gr}(P^1, P^3)$, namely it satisfies only $(\ast_1)$ but not $(\ast_2)$, where $S$ is the tautological subbundle on $G$.

We can now easily conclude the proof of Theorem 1.11:

Proof of Theorem 1.11. As the standard conjecture is proven for $F_b$ in [10] (this can also be seen more elementarily by noting that the incidence correspondence $I$ induces an isomorphism from $H^0(F_b, \mathbb{Q})$ to $H^2(F_b, \mathbb{Q})$), numerical equivalence coincides with homological equivalence on powers of $F_b$. Since any cycle of $F^5 \times F^5$ is the restriction of a cycle of $F \times F$, it is enough to show that for any $b \in B^5$, the restriction of a cycle $\gamma \in \text{CH}(F \times F)$ to $F_b \times F_b$ is zero if and only if it is homologically trivial, which is proven by combining Proposition 6.3 and Proposition 6.4. \qed

With Theorem 1.11 being proven, we proceed to study the zero-cycles and codimension-2 cycles of the LLSvS hyper-Kähler eightfolds. The key input is Voisin’s degree 6 dominant rational map [44, Proposition 4.8]
\[ F \times F \to \mathbb{Z}. \]

Consider the family version of Voisin’s construction (over $B^\infty$): $\psi : F^\infty \times_{B^\infty} F^\infty \to \mathbb{Z}$. 

Proof of Theorem 1.12. Take a resolution of indeterminacies:
\[ \widetilde{\mathcal{F}}^\circ \times_{\mathcal{B}^\circ} \mathcal{F}^\circ \]
\[ \tau \downarrow \downarrow \]
\[ f \]
\[ \mathcal{F}^\circ \times_{\mathcal{B}^\circ} \mathcal{F}^\circ \rightarrow \mathcal{Z} \]

For (i), let \( \gamma \in \text{CH}^8(\mathcal{Z}) \) be a relative zero-cycle whose degree on fibers is zero. Then, for any \( b \in B^\circ \),
\[ (\tau_\ast f_\ast(\gamma))|_{F_b \times F_b} = \tau_{b_\ast}(f_\ast(\gamma)|_{F_b \times F_b}) = \tau_{b_\ast}(f_\ast(\gamma)|_{\mathcal{Z}_b}). \]
Thus \( \tau_\ast f_\ast(\gamma) \) is a relative zero-cycle of fiber degree zero on \( \mathcal{F}^\circ \times_{\mathcal{B}^\circ} \mathcal{F}^\circ \) and by Theorem 1.11, we know that
\[ \tau_{b_\ast}(f_\ast(\gamma)|_{\mathcal{Z}_b}) = 0 \text{ in } \text{CH}^8(F_b \times F_b). \]

For \( b \in B^\circ \) general, \( \tau_b \) is birational hence induces an isomorphism on \( \text{CH}_0 \), hence \( f_\ast(\gamma|_{\mathcal{Z}_b}) = 0 \). Moreover, since \( f_b \) is generically finite of degree 6 (still under the assumption that \( b \) is general), we have
\[ \gamma|_{\mathcal{Z}_b} = \frac{1}{6} f_{b_\ast}(\gamma|_{\mathcal{Z}_b}) = 0. \]
A specialization argument shows that \( \gamma|_{\mathcal{Z}_b} = 0 \) for all \( b \in B^\circ \).

For (ii), i.e., codimension-2 cycles: since \( H^3(Z_b, \mathbb{Q}) = H^3(F_b \times F_b) = 0 \), any cycle in \( \text{CH}^2(Z_b) \) or \( \text{CH}^2(F_b \times F_b) \) is homologically trivial if and only if its Abel–Jacobi invariant vanishes. Now the same proof as in (i) works because the subspace of Abel–Jacobi kernel for codimension-2 cycles \( \text{CH}_{AJ}^2 \), just as \( \text{CH}_0 \), is a birational invariant (for smooth projective varieties), hence
\[ \tau_{b_\ast} : \text{CH}^2(F_b \times F_b)_{\hom} \rightarrow \text{CH}^2(F_b \times F_b)_{\hom} \]
is an isomorphism. \( \square \)

Proof of Corollary 1.13. In view of Theorem 1.12, this is just a special case of Proposition 2.5. \( \square \)
Let $X$ be a smooth cubic fourfold and $F$ be its Fano variety of lines, which is a hyper-Kähler fourfold by [6]. In this appendix, we establish a new relation (Theorem A.1), up to rational equivalence, among 3-dimensional tautological cycle classes of $F \times F$. Some interesting applications of this tautological relation are also discussed. We try to keep the appendix as self-contained as possible.

Throughout this appendix, let us fix the following notation:

- $P^5$ is the ambient space and $X$ is a smooth cubic hypersurface in it.
- $h := c_1(O_{P^5}(1))$; $h|_X$ is still denoted by $h$.
- $G := Gr(P^1, P^5) \cong Gr(2, 6)$ is the Grassmannian of projective lines in $P^5$.
- $F := F(X)$ is the Fano variety of lines of $X$.
- $S$ is the tautological subbundle on $G$.
- $\gamma := c_1(S^\vee)$ is the Plücker polarization class; $\gamma|_F$ is still denoted by $\gamma$.
- $c := c_2(S)$; $c|_F$ is still denoted by $c$.
- $h_i := pr_i^*(h)$, $g_i := pr_i^*(\gamma)$ and $c_i := pr_i^*(c)$ where $pr_i$ is the $i$-th projection.
- Let $P := P(S|_F)$ be the incidence variety in $F \times X$. Then the natural projection $p : P \to F$ is the universal projective line and $q : P \to X$ is the evaluation map.
- $I \subset F \times F$ is the incidence subvariety parametrizing pairs of intersecting lines contained in $X$.
- $\tilde{I} := P \times_X P$. Note that $I$ is its image in $F \times F$ via the natural projection.

The main result of this appendix is the following.

**Theorem A.1.** There exists a polynomial $Q$ (of weighted degree 5), such that the following equality holds in $CH^5(F \times F)$:

$$6\Delta_*(\gamma) + g_1g_2(g_1 + g_2) \cdot I = Q(g_1, g_2, c_1, c_2)$$

where $\Delta : F \hookrightarrow F \times F$ is the diagonal embedding.

**Remark A.2.** The polynomial $Q$ is not unique. A cohomological computation shows that

$$Q(g_1, g_2, c_1, c_2) = \frac{1}{4}(g_1^4g_2 + g_1g_2^4) + \frac{7}{12}(g_1^3g_2^2 + g_1^2g_2^3)$$

is one possible choice of $Q$.

**A.1. Proof of the tautological relation.** We have the following diagram

$$
\begin{array}{ccc}
\tilde{I} & \longrightarrow & X \\
\downarrow_i & & \downarrow_{\Delta_X} \\
P \times P & \xrightarrow{(p, q)} & X \times X \\
\downarrow_{(p, p)} & & \downarrow_{(p, p)} \\
F \times F & & 
\end{array}
$$

Let us first introduce some natural cycles on $F \times F$: for any $i \in \mathbb{N}$, define

$$\Gamma_{hi} := (p, p)_*(q, q)^*(\Delta_X(h^i)) \in CH^{4i+2}(F \times F).$$
Note that \( \Gamma_{i0} \) is nothing but the incidence correspondence \( I \). Geometrically, \( \Gamma_{i0} \) is represented by the locus of pairs of lines contained in \( X \) intersecting at a point which lies on the intersection of \( i \) general hyperplane sections of \( X \).

**Lemma A.3.** For any \( i > 0 \), the cycle \( \Gamma_{i0} \) is a polynomial of \( g_1, g_2, c_1, c_2 \). Precisely,

\[
\begin{align*}
\Gamma_{i0} &= \frac{1}{18}(g_1^3 + 6g_1^2g_2 + 6g_1g_2^2 + g_2^3 - 6g_1c_2 - 6g_2c_1); \\
\Gamma_{i1} &= \frac{1}{18}(g_1^2g_2 + 6g_1g_2^2 + g_1g_2^2 - 6g_1^2c_2 - 6g_2^2c_1 + 6c_1c_2); \\
\Gamma_{i2} &= \frac{1}{18}(g_1^3g_2 + g_1^2g_2^2 - g_1^3c_2 - g_2^3c_1); \\
\Gamma_{i3} &= \frac{1}{108}g_1^3g_2^3. 
\end{align*}
\]

**Proof.** A slightly more complicated (but equivalent) form of the first two formulas is proven in [35, Proposition A.6]. For the convenience of the reader, we give a complete proof here. The excess intersection formula [18, §6.3] applied to the following cartesian diagram

\[
\begin{array}{ccc}
X & \rightarrow & \mathbb{P}^5 \\
\downarrow \Delta_X & & \downarrow \Delta_P \\
X \times X & \rightarrow & \mathbb{P}^5 \times \mathbb{P}^5
\end{array}
\]

yields that for any \( i \in \mathbb{N} \), we have in \( \text{CH}(X \times X) \)

\[
3\Delta_{X*}(h^{i+1}) = \Delta_{P*}(h^i)|_{X \times X}.
\]

From \( \Delta_{P*}(h^i) = h_1^ih_2^i + \cdots + h_1^ih_2^i \) we obtain

\[
\Delta_{X*}(h^i) = \frac{1}{3} \left( h_1^ih_2^i + \cdots + h_1^ih_2^i \right).
\]

Therefore

\[
\Gamma_{i0} = (p, p), (q, q)^*(\Delta_{X*}(h^i)) \\
= \frac{1}{3} (p, p), (q, q)^* \left( h_1^ih_2^i + \cdots + h_1^ih_2^i \right) \\
= \frac{1}{3} (f_4 \times f_1 + \cdots + f_i \times f_4)
\]

where \( f_j := p, q^*(h^j) \) and \( \times \) is the exterior product \( \text{pr}_1^*(-) \cdot \text{pr}_2^*(-) \). All the formulas in the statement then follow from the facts that \( f_1 = 1, f_2 = g, f_3 = g^2 - c, f_4 = \frac{1}{6}g^3 \) (cf. [35, Lemma A.4] and [41, Lemma 3.2] and [41, Lemma 3.5]).

Define \( I_0 := /\Delta_F \) the subvariety of \( F \times F \) parametrizing pairs of distinct intersecting lines in \( X \). We then have a natural morphism

\[
q_0 : I_0 \rightarrow X
\]

which sends two lines to their intersection point.

**Lemma A.4.** The inclusion \( I_0 \hookrightarrow F \times F \Delta_F \) is a local complete intersection and the Chern classes of the normal bundle \( N := N_{I_0/F \times F \Delta_F} \) are given by

\[
\begin{align*}
c_1(N) &= (g_1 + g_2)|_{I_0} - q_0^*(h) ; \\
c_2(N) &= (g_1^2 + g_1g_2 + g_2^2)|_{I_0} - 3(g_1 + g_2)|_{I_0} \cdot q_0^*(h) + 6q_0^*(h^2). 
\end{align*}
\]
Proof. Note that \( \tilde{I} \subset P \times P \) is a local complete intersection (since \( \tilde{I} \subset P \times P \) is obtained from the local complete intersection \( \Delta_X \subset X \times X \) via base change) and that \( \tilde{I}\Delta \subset P \times P \) is a section of \( P \times P \rightarrow F \times F \) over \( I_0 \). We apply \([18, B.7.5]\) and see that \( I_0 \subset F \times F \backslash \Delta_F \) is a local complete intersection. Using the section \( \tilde{I}\Delta \), we view \( I_0 \) as a subvariety of \( P \times P \). Then we get the following short exact sequence

\[
0 \rightarrow \text{pr}_1^*T_{P/F} \oplus \text{pr}_2^*T_{P/F} \rightarrow N_{I_0/P \times P} \rightarrow N_{I_0/F \times F} \rightarrow 0
\]

Note that by construction, we have

\[
N_{I_0/P \times P} = q_0^*T_X.
\]

The Chern classes of \( N_{I_0/F \times F} \) are computed as follows

\[
c(N) = \frac{q_0^*c(T_X)}{\text{pr}_1^*c(T_{P/F}) \cdot \text{pr}_2^*c(T_{P/F})} = \frac{(1 + h)^6}{(1 + 3h)(1 + 2q_0^*h - g_1|_{I_0})(1 + 2q_0^*h - g_2|_{I_0})}
\]

The lemma follows from the expansion of the above equation.

Remark A.5. The previous lemma implies that

\[
I^2_{|F \times F\backslash \Delta_F} = I \cdot (g_1^2 + g_1g_2 + g_2^2) - 3(g_1 + g_2)\Gamma_h + 6\Gamma_{h^2}.
\]

Thus by Lemma A.3 there exists \( \alpha \in \mathbb{Q} \) and a polynomial \( \Gamma_2 \), such that in \( \text{CH}^4(F \times F) \) we have

\[
I^2 = \alpha \cdot \Delta_F + I \cdot (g_1^2 + g_1g_2 + g_2^2) + \Gamma_2(g_1, g_2, c_1, c_2).
\]

for some \( \alpha \in \mathbb{Q} \). This was proven by Voisin \([41]\). In fact, \( \alpha = 2 \), as is computed in \([35]\) Proposition 17.4.

Proof of Theorem A.1. Let us first prove the theorem for a general cubic fourfold \( X \). Fix three general hyperplane sections \( H_1, H_2, H_3 \) of \( X \). For \( i = 1, 2, 3 \), let

\[
Z_i := \{ (l, l') \in F \times F | l \cap l' \cap H_1 \cap \cdots \cap H_i \neq \emptyset \}.
\]

On the one hand, as is mentioned before, the class of \( Z_i \) in \( \text{CH}^{2+i}(F \times F) \) is equal to \( \Gamma_{h^i} \); on the other hand, denoting by \( Z^o_i := Z_i \backslash \Delta_{F} \) the complement of the diagonal in \( Z_i \), the class of \( Z^o_i \) in \( \text{CH}^4(I_0) \) is equal to \( q_0^*(h^i) \) by definition. We have thus the diagram

\[
\begin{array}{ccc}
Z^o_3 \subset Z^o_2 \subset Z^o_1 \xrightarrow{i} I_0 \xrightarrow{\iota} F \times F \backslash \Delta_F \\
\downarrow q_0 \\
X
\end{array}
\]

Denoting by \( N \) the normal bundle of \( \iota \), we obtain

\[
I \cdot \Gamma_{h|F \times F \backslash \Delta_F} = I_0 \cdot \iota_*q_0^*(h) = \iota_* \left( q_0^*(h) \cdot c_2(N) \right) = \iota_* \left( (g_1^2 + g_1g_2 + g_2^2)|_{I_0} \cdot q_0^*(h) - 3(g_1 + g_2)|_{I_0} \cdot q_0^*(h^2) + 6q_0^*(h^3) \right) = \left( (g_1^2 + g_1g_2 + g_2^2) \cdot Z_1 - 3(g_1 + g_2) \cdot Z_2 + 6Z_3 \right)|_{F \times F \backslash \Delta_F} = \left( (g_1^2 + g_1g_2 + g_2^2) \cdot \Gamma_h - 3(g_1 + g_2) \cdot \Gamma_{h^2} + 6\Gamma_{h^3} \right)|_{F \times F \backslash \Delta_F}
\]
where the third equality uses Lemma A.4. By Lemma A.3, there exists a polynomial $P_1$ such that
\[ I \cdot \Gamma_h|_{F \times F \setminus \Delta} = P_1(g_1, g_2, c_1, c_2)|_{F \times F \setminus \Delta}. \]
Here more precisely, one can compute by Lemma A.3 and the relation $12gc = 5g^3$ that
\[ P_1(g_1, g_2, c_1, c_2) = \frac{5}{12} \left( 4g_1^3g_2 + 4g_1^2g_2^2 + 4g_1g_2^3 + g_1g_2^4 - 3g_1^3c_2 - 3g_2^3c_1 \right). \]
By the localization short exact sequence of Chow groups, there exists an element $D \in CH^1(F)$, such that in $CH^5(F \times F)$ we have
\[ I \cdot \Gamma_h + \Delta_*(D) = P_1(g_1, g_2, c_1, c_2). \]
Since $X$ is assumed (for now) to be general, $CH^1(F)$ is generated by $g$, hence $D = \lambda g$ for some $\lambda \in \mathbb{Q}$. It yields that in $CH^5(F \times F)$,
\[ I \cdot \Gamma_h + \lambda \Delta_*(g) = P_1(g_1, g_2, c_1, c_2). \]
However, we know that $I \cdot c_1, I \cdot c_2, I \cdot g^3$ and $I \cdot g^2$ are polynomials of $g_1, g_2, c_1, c_2$ by \[35\] Lemma 17.6] (cf. the known relations collected in the proof of Proposition 6.4). The first formula in Lemma A.3 then yields that
\[ I \cdot \Gamma_h = \frac{1}{3} I \cdot \left( g_1^2g_2 + g_1g_2^2 \right) + P_2(g_1, g_2, c_1, c_2) \]
for some polynomial $P_2$.

Putting (14) and (15) together, we know that there exists a polynomial $Q$ such that the following equality holds in $CH^5(F \times F)$:
\[ 3\lambda \cdot \Delta_*(g) + I \cdot \left( g_1^2g_2 + g_1g_2^2 \right) = Q(g_1, g_2, c_1, c_2). \]
By considering the action of both sides on the cohomology, we easily see that $\lambda = 2$ and that
\[ Q(g_1, g_2, c_1, c_2) = \frac{1}{4} (g_1^3g_2 + g_1g_2^3) + \frac{7}{12} (g_1^2g_2^2 + g_1^2g_2^2). \]
Therefore the desired relation is proven for a general cubic fourfold. As all the cycles appearing are universally defined in the universal Fano variety of lines, a specialization argument shows that this relation must also hold for any smooth cubic fourfold.

**A.2. Some applications to the Fourier decomposition of $F$.** Our aim is to use Theorem [1.11] which is based on Theorem A.1 to complement the results of [35] concerning the multiplicative structure of the Chow motive of the Fano variety of lines on a smooth cubic fourfold.

**A.2.1. An explicit Chow–Künneth decomposition for $F$.** Recall that a Chow–Künneth decomposition for a smooth projective variety $X$ of dimension $d$ is a decomposition of the diagonal $\Delta_X \in CH^d(X \times X)$ into a sum $\Delta_X = \pi_X^0 + \cdots + \pi_X^{2d}$ of mutually orthogonal idempotent correspondences $\pi_X^i \in CH^d(X \times X)$ whose action in cohomology is given by $(\pi_X^i)_*H^*(X, \mathbb{Q}) = H^*(X, \mathbb{Q})$. It is a conjecture of Murre that all smooth projective varieties should admit a Chow–Künneth decomposition. In [35], it is shown that the Fano variety of lines on a smooth cubic fourfold admits a Chow–Künneth decomposition; see especially [35, Theorem 3.3]. Such a decomposition is obtained by modifying the following correspondences in $CH^4(F \times F)$:
\[ \pi_F^0 = \frac{1}{23} \cdot \frac{L^2}{25} l_1, \quad \pi_F^1 = \frac{1}{25} L \cdot l_1, \quad \pi_F^2 = \frac{1}{2} \left( L^2 - \frac{1}{25} l_1 \cdot l_2 \right), \quad \pi_F^6 = \frac{1}{25} L \cdot l_2, \quad \pi_F^8 = \frac{1}{23} \cdot \frac{l_2}{25}. \]
Here, \( L := \frac{1}{3}(g_1^2 + g_1 g_2 + g_2^2 - c_1 - c_2) - I \in \text{CH}^2(F \times F) \) is a, and in fact “the” by Proposition 6.4 tautological cycle representing the Beauville–Bogomolov form; see \[35\] Proposition 19.1. The cycle \( I \in \text{CH}^2(F) \) is the restriction of \( L \) to the diagonal, and, as before, a subscript \( i \) indicates the pull-back along the projection \( F \times F \to F \) to the \( i \)-th factor.

As was expected from \[35\] Conjecture 3, these correspondences already define a Chow–Künneth decomposition:

**Proposition A.6.** The correspondences in \[16\] define a Chow–Künneth decomposition of \( F \).

**Proof.** The correspondences \( \pi^{2i}_F \) of \[16\] are cycles on \( F \times F \) that belong to the image of the restriction map \( \text{CH}(F \times \mathcal{F}) \to \text{CH}(F \times F) \), and they define a Künneth decomposition of the diagonal in cohomology by \[35\] Corollary 1.7. (Here \( \mathcal{F} \to B \) is the universal Fano variety of lines as defined in \[35\].) It follows readily from Theorem 1.11 that they define a Chow–Künneth decomposition. \( \square \)

A.2.2. A new multiplicativity statement. Using the Chow–Künneth decomposition \[16\] given by Proposition A.6 we can define, for all integers \( i \) and \( j \),

\[
\text{CH}^i(F)(j) := (\pi^{2i-j}_F), \text{CH}^i(F).
\]

Concretely, we have (cf. \[35\])

\[
\begin{align*}
\text{CH}^4(F) &= \text{CH}^4(F)(0) \oplus \text{CH}^4(F)(2) \oplus \text{CH}^4(F)(4) \\
\text{CH}^3(F) &= \text{CH}^3(F)(0) \oplus \text{CH}^3(F)(2) \\
\text{CH}^2(F) &= \text{CH}^2(F)(0) \oplus \text{CH}^2(F)(2) \\
\text{CH}^1(F) &= \text{CH}^1(F)(0) \\
\text{CH}^0(F) &= \text{CH}^0(F)(0).
\end{align*}
\]

In \[35\], it was proven that, for the Fano variety of lines on a very general cubic fourfold, the decomposition \( \text{CH}^i(F)(j) \) defines a bigrading on the Chow ring \( \text{CH}(F) \), in the sense that for all integers \( i, i', j, j' \) we have

\[
\text{CH}^i(F)(j) \cdot \text{CH}^{i'}(F)(j') \subseteq \text{CH}^{i+i'}(F)(j+j').
\]

In the case of the Fano variety of lines on a non-very general cubic fourfold, the following two relations could not be established (see \[35\] Remark 22.9) :

\[
\begin{align*}
\text{CH}^1(F) \cdot \text{CH}^2(F)(0) &\subseteq \text{CH}^3(F)(0) ; \\
\text{CH}^2(F)(0) \cdot \text{CH}^2(F)(0) &\subseteq \text{CH}^4(F)(0) = Q \cdot 0_F.
\end{align*}
\]

Using Theorem 1.11 which is based on the new relation \[12\], we can now prove one of the missing two inclusions :

**Proposition A.7.** Let \( F \) be the Fano variety of lines on a smooth cubic fourfold. Then

\[
\text{CH}^1(F) \cdot \text{CH}^2(F)(0) = \text{CH}^3(F)(0).
\]

**Proof.** We first show that \( \text{CH}^3(F)(0) \subseteq \text{CH}^1(F) \cdot \text{CH}^2(F)(0) \). On the one hand, the cycle class map \( \text{CH}^3(F)(0) \to H^6_{\text{alg}}(F, \mathbb{Q}) \) is an isomorphism; on the other hand, the hard Lefschetz isomorphism implies that \( H^6_{\text{alg}}(F, \mathbb{Q}) \) is generated by \( g^2 \cdot H^2_{\text{alg}}(F, \mathbb{Q}) = g^2 \cdot \text{CH}^1(F) \). Hence \( \text{CH}^3(F)(0) \) is generated by intersections of three divisors, which is contained in \( \text{CH}^1(F) \cdot \text{CH}^2(F)(0) \) since we know \( \text{CH}^1(F) \cdot \text{CH}^1(F) \subseteq \text{CH}^2(F)(0) \).
For the inverse inclusion, which is \([17]\), by \([35]\) Proposition 22.7, we only need to show that if \(\alpha\) is a cycle in \(\text{CH}^2(F(0))\), then \(g \cdot \alpha\) belongs to \(\text{CH}^3(F(0))\). To this end, we consider the correspondence
\[
\Gamma := \pi^k_F \circ \Gamma_i \circ \iota \circ \tau^k \in \text{CH}^3(F \times F),
\]
where \(\iota : H \hookrightarrow F\) denotes the inclusion of a hyperplane with respect to the Plücker embedding. Clearly, \(\Gamma\) is homologically trivial. But \(\Gamma\) is universally defined, and so Theorem [11] implies that \(\Gamma\) is rationally trivial. The action of \(\Gamma\) on \(\text{CH}^2(F(0))\) is the same as
\[
\text{CH}^2(F(0)) \xrightarrow{\delta} \text{CH}^3(F(0)) \xrightarrow{\rho} \text{CH}^3(F(2))
\]
(where the second arrow is projection on a direct summand), and so we are done. \(\Box\)

With notations as in \(\S 6\), it seems that the final missing inclusion \([18]\) cannot be obtained from considering the subring \(\text{Im}(\text{CH}(F \times_B F) \to \text{CH}(F_b \times X_b))\). Rather, a streamlined proof of all inclusions \(\text{CH}^i(F(0)) \cdot \text{CH}^j(F(0)) \subseteq \text{CH}^{i+j}(F(0))\) would follow from establishing that the Chow–Künneth decomposition \([16]\) is multiplicative in the sense of \([35] \S 8\), meaning that
\[
\pi^k_F \circ \delta_F \circ (\pi^k_F \otimes \pi^l_F) = 0 \quad \text{in} \quad \text{CH}^8(F \times F \times F), \quad \text{for all} \quad k \neq i + j,
\]
where \(\delta_F\) denotes the class of the small diagonal in \(F \times F \times F\) viewed as a correspondence from \(F \times F \times F\). This in turn would follow from showing the generalized Franchetta conjecture for the relative cube of the universal Fano variety of lines, i.e., one would need to show that the subring
\[
\text{Im}(\text{CH}(F \times_B F \times_B F) \to \text{CH}(F_b \times F_b \times F_b))
\]
joins into cohomology by the cycle class map for all \(b\). An approach would consist in first showing that this subring consists of “tautological cycles” and then in establishing enough “tautological relations”, as was done in Propositions \(6.3\) and \(6.4\) in the case of the relative square.
