UNIQUENESS FOR NEUMANN PROBLEMS FOR NONLINEAR ELLIPTIC EQUATIONS

M.F. BETTA, O. GUIBÉ, AND A. MERCALDO

Abstract. In the present paper we prove uniqueness results for solutions to a class of Neumann boundary value problems whose prototype is
\[
\begin{aligned}
-\text{div}((1 + |\nabla u|^2)^{(p-2)/2}\nabla u) - \text{div}(c(x)|u|^{p-2}u) &= f & \text{in } \Omega, \\
((1 + |\nabla u|^2)^{(p-2)/2}\nabla u + c(x)|u|^{p-2}u) \cdot \mathbf{n} &= 0 & \text{on } \partial \Omega,
\end{aligned}
\]
where \(\Omega\) is a bounded domain of \(\mathbb{R}^N\), \(N \geq 2\), with Lipschitz boundary, \(1 < p < N\), \(\mathbf{n}\) is the outer unit normal to \(\partial \Omega\), the datum \(f\) belongs to \(L^{(p^*)'}(\Omega)\) or to \(L^1(\Omega)\) and satisfies the compatibility condition \(\int_{\Omega} f \, dx = 0\). Finally the coefficient \(c(x)\) belongs to an appropriate Lebesgue space.

Mathematics Subject Classification: MSC 2000: 35J25
Key words: Nonlinear elliptic equations, Neumann problems, renormalized solutions, uniqueness results

1. Introduction

In the present paper we prove uniqueness results for solutions to a class of Neumann boundary value problems whose prototype is
\[
\begin{aligned}
-\text{div}((1 + |\nabla u|^2)^{(p-2)/2}\nabla u) - \text{div}(c(x)|u|^{p-2}u) &= f & \text{in } \Omega, \\
((1 + |\nabla u|^2)^{(p-2)/2}\nabla u + c(x)|u|^{p-2}u) \cdot \mathbf{n} &= 0 & \text{on } \partial \Omega,
\end{aligned}
\]
where \(\Omega\) is a bounded domain of \(\mathbb{R}^N\), \(N \geq 2\), with Lipschitz boundary, \(1 < p < N\), \(\mathbf{n}\) is the outer unit normal to \(\partial \Omega\), the datum \(f\) belongs to \(L^{(p^*)'}(\Omega)\), where \(p^* = \frac{Np}{N-p}\), or to \(L^1(\Omega)\) and satisfies the compatibility condition
\[
\int_{\Omega} f \, dx = 0.
\]
Finally the coefficient \(c(x)\) belongs to an appropriate Lebesgue space which will be specified later.

The main difficulties in studying existence or uniqueness for this type of problems are due to the presence of a lower order term, the lower summability of the datum \(f\) and the boundary Neumann conditions.
The existence for Neumann boundary value problems with $L^1$-data when $c = 0$ has been treated in various contests. In [3], [14], [19], [20] and [29] the existence of a distributional solution which belongs to a suitable Sobolev space and which has null mean value is proved. Nevertheless when $p$ is close to 1, i.e. $p \leq 2 - 1/N$, the distributional solution to problem (1.1) does not belong to a Sobolev space and in general is not a summable function; this implies that its mean value has not meaning and any existence result for distributional solution with null mean value cannot hold. This difficulty is overcome in [18] by considering solutions $u$ which are not in $L^1(\Omega)$, but for which $\Phi(u)$ is in $L^1(\Omega)$, where $\Phi(t) = \int_0^t \frac{ds}{(1+|s|)^\alpha}$ with appropriate $\alpha > 1$.

In [1] the case where both the datum $f$ and the domain $\Omega$ are not smooth enough is studied and the existence and continuity with respect to the data of solutions whose median is equal to zero is proved with a natural process of approximations and symmetrization techniques.

We recall that the median of $u$ is defined by

$$(1.2) \quad \text{med}(u) = \sup\{t \in \mathbb{R} : \text{meas}\{u > t\} > \text{meas}(\Omega)/2\}.$$  

The existence for solutions having null median to problem (1.1) when $c \neq 0$ are proved in [8].

We explicitly remark that when the datum $f$ has a lower summability, i.e. it is just an $L^1$-function, one has to give a meaning to the notion of solution; such a question has been faced already in the case where Dirichlet boundary conditions are prescribed, by introducing different notion of solutions (cf. [7], [17], [27], [28]). Such notion turn out to be equivalent, at least when the datum is an $L^1$-function.

In the present paper, when $f \in L^1(\Omega)$, we refer to the so-called renormalized solutions (see [16], [27], [28]) whose precise definition is recalled in Section 2.

The main novelty of this article is to prove uniqueness (up to additive constants) results for renormalized solutions to problem (1.1) having null median and whose existence has been proved in [8].

To our knowledge uniqueness results for problem (1.1) are new even in the variational case, i.e. when $f$ belongs to $L^{(p')'}(\Omega)$ and the usual notion of weak solution is considered.

When $c(x) = 0$ and $f$ is an element of the dual space of the Sobolev space $W^{1,p}(\Omega)$, the existence and uniqueness (up to additive constants) of weak solutions to problem (1.1) is consequence of the classical theory of pseudo monotone operators (cfr. [25], [26]), while existence results for weak solutions to problem (1.1) when the lower order term appears have been proved in [8].
As pointed out we will prove different results according to the summability of \( f \), i.e. \( f \in L^{(p^*)'}(\Omega) \) or \( f \in L^1(\Omega) \) and to the value of \( p \), i.e. \( p \leq 2 \) and \( p \geq 2 \). As far as \( p \) is concerned such a difference is due to the principal part of the operator, which we consider. Actually we assume that the principal part \(-\text{div}(a(x, Du))\) is not degenerate when \( p > 2 \), i.e. in the model case \(-\text{div}(a(x, \nabla u)) = -\text{div}((1 + |\nabla u|^{2(p-2)/2})\nabla u)\). But such an assumption is not required when \( p \leq 2 \), that is for such values of \( p \) we prove uniqueness results for operators whose prototype is the so-called \( p \)-Laplace operator, \(-\Delta_p u = -\text{div}(|\nabla u|^{p-2}\nabla u)\).

Let us explain the main ideas of our results. To this aim let us consider the simpler case of weak solutions and \( p = 2 \). When a Dirichlet boundary value problem is considered, following an idea of Artola [4] (see also [13, 15]), denoted by \( u \) and \( v \) two solutions, one can use the test function \( T_k(u - v) \) and obtain

\[
\lim_{k \to 0} \frac{1}{k^2} \int_{\Omega} |\nabla T_k(u - v)|^2 \, dx = 0.
\]

Since \( u, v \in H^1_0(\Omega) \), Poincaré inequality implies that

\[
\int_{\Omega} |\text{sign}(u - v)|^2 \, dx = \lim_{k \to 0} \frac{1}{k^2} \int_{\Omega} |T_k(u - v)|^2 \, dx = 0,
\]

from which one can deduce that \( u = v \) a.e. in \( \Omega \). In contrast when we consider Neumann boundary conditions and two solutions \( u, v \in H^1(\Omega) \) having null median, by using \( T_k(u - v) \) we can prove equality (1.3), but Poincaré-Wirtinger inequality does not allow to get

\[
\int_{\Omega} |\text{sign}(u - v)|^2 \, dx = 0
\]

and therefore that \( u = v \) a.e. in \( \Omega \). However (1.3) and Poincaré-Wirtinger inequality, allow to deduce that \( u = v \) a.e. in \( \Omega \) either \( u > v \) a.e. in \( \Omega \) either \( u < v \) a.e. in \( \Omega \). Then we prove that \( u > v \) a.e. in \( \Omega \) or \( u < v \) a.e. in \( \Omega \) leads to a contradiction: it is done through a new test function

\[
w_{k, \delta} = \frac{T_k(u - v)}{k} \left( \frac{T_\delta(u^+)}{\delta} - \frac{T_\delta(v^-)}{\delta} \right),
\]

where \( T_k \) denote the truncate function at height \( k \) and

\[
u^+ = \max\{0, u\}, \quad v^- = \max\{0, -v\}.
\]

Neumann problems have been studied by a different point of view in [21], [22], while existence or uniqueness results for Dirichlet boundary value problems for nonlinear elliptic equations with \( L^1 \)-data are treated in [11],[12] and was continued in various contributions, including [2],
mixed boundary value problems have been also studied, for example, in [6], [19].

The paper is organized as follows. In Section 2 we detail the assumptions and we give the definition of a renormalized solution to (1.1). Section 3 is devoted to prove two uniqueness results for weak solutions when the datum is in the Lebesgue space \(L^{p^*}(\Omega)\). In Section 4 we state our main results, Theorem 4.1, Theorem 4.2, where we prove the uniqueness of a renormalized solution to (1.1) when datum is a \(L^1\) function.

2. Assumptions and definitions

Let us consider the following nonlinear elliptic Neumann problem

\[
\begin{cases}
-\text{div} \left( a(x, \nabla u) + \Phi(x, u) \right) = f \quad \text{in } \Omega, \\
(a(x, \nabla u) + \Phi(x, u)) \cdot n = 0 \quad \text{on } \partial \Omega,
\end{cases}
\]  

(2.1)

where \(\Omega\) is a bounded domain of \(\mathbb{R}^N\), \(N \geq 2\), having finite Lebesgue measure and Lipschitz boundary, \(n\) is the outer unit normal to \(\partial \Omega\). We assume that \(p\) is a real number such that \(1 < p < N\). The function \(a : \Omega \times \mathbb{R}^N \mapsto \mathbb{R}^N\) is a Carathéodory function such that

\[
a(x, \xi) \cdot \xi \geq \alpha |\xi|^p, \quad \alpha > 0,
\]  

(2.2)

\[
|a(x, \xi)| \leq c( |\xi|^{p-1} + a_0(x) ) , \quad c > 0, \quad a_0 \in L^{p'}(\Omega), \quad a_0 \geq 0,
\]  

(2.3)

for almost every \(x \in \Omega\) and for every \(\xi \in \mathbb{R}^N\). Moreover \(a\) is strongly monotone, that is a constant \(\beta > 0\) exists such that

\[
(a(x, \xi) - a(x, \eta)) \cdot (\xi - \eta) \geq \begin{cases}
\beta \frac{|\xi - \eta|^2}{(|\xi| + |\eta|)^{2-p}} & \text{if } 1 < p \leq 2, \\
\beta |\xi - \eta|^2(1 + |\xi| + |\eta|)^{p-2} & \text{if } p \geq 2,
\end{cases}
\]

(2.4)

for almost every \(x \in \Omega\) and for every \(\xi, \eta \in \mathbb{R}^N, \xi \neq \eta\).

We assume that \(\Phi : \Omega \times \mathbb{R} \mapsto \mathbb{R}^N\) is a Carathéodory function which satisfies the following “growth condition”

\[
|\Phi(x, s)| \leq c(x)(1 + |s|)^{p-1}, \quad c \in L^t(\Omega), \quad c \geq 0,
\]  

(2.5)

with

\[
t \geq \frac{N}{p-1}
\]  

(2.6)

for a.e. \(x \in \Omega\) and for every \(s \in \mathbb{R}\). Moreover we assume that such function is locally Lipschitz continuous with respect to the second variable,
that is
\[(2.7) \quad |\Phi(x, s) - \Phi(x, z)| \leq c(x)(1 + |s| + |z|)\tau |s - z|, \quad \tau \geq 0,\]
for almost every \( x \in \Omega \), for every \( s, z \in \mathbb{R} \).

Finally we assume that the datum \( f \) is a measurable function in a Lebesgue space \( L^r(\Omega) \), \( 1 \leq r \leq +\infty \), which belongs to the dual space of the classical Sobolev space \( W^{1,p}(\Omega) \) or is just an \( L^1 \) function. Moreover it satisfies the compatibility condition
\[(2.8) \quad \int_{\Omega} f \, dx = 0.\]

As explained in the Introduction we deal with solutions whose median is equal to zero. Let us recall that if \( u \) is a measurable function, we denote the median of \( u \) by
\[(2.9) \quad \text{med}(u) = \sup \left\{ t \in \mathbb{R} : \text{meas}\{x \in \Omega : u(x) > t\} > \frac{\text{meas}(\Omega)}{2} \right\}.\]

Let us explicitly observe that if \( \text{med}(u) = 0 \) then
\[
\text{meas}\{x \in \Omega : u(x) > 0\} \leq \frac{\text{meas}(\Omega)}{2},
\]
\[
\text{meas}\{x \in \Omega : u(x) < 0\} \leq \frac{\text{meas}(\Omega)}{2}.
\]
In this case a Poincaré-Wirtinger inequality holds (see e.g. [30]):

**Proposition 2.1.** If \( u \in W^{1,p}(\Omega) \), then
\[(2.10) \quad \|u - \text{med}(u)\|_{L^p(\Omega)} \leq C\|\nabla u\|_{(L^p(\Omega))^N}\]
where \( C \) is a constant depending on \( p, N, \Omega \).

When the datum \( f \) is not an element of the dual space of the classical Sobolev space \( W^{1,p}(\Omega) \), the classical notion of weak solution does not fit. We will refer to the notion of renormalized solution to (2.1) (see [16, 28] for elliptic equations with Dirichlet boundary conditions) which we give below.

In the whole paper, \( T_k, k \geq 0 \), denotes the truncation at height \( k \) that is \( T_k(s) = \min(k, \max(s, -k)) \), \( \forall s \in \mathbb{R} \).

**Definition 2.2.** A real function \( u \) defined in \( \Omega \) is a renormalized solution to (2.1) if
\[(2.11) \quad u \text{ is measurable and finite almost everywhere in } \Omega,
\]
\[(2.12) \quad T_k(u) \in W^{1,p}(\Omega), \text{ for any } k > 0,
\]
\[(2.13) \quad \lim_{n \to +\infty} \frac{1}{n} \int_{\{x \in \Omega : |u(x)| < n\}} a(x, \nabla u) \nabla u \, dx = 0\]

\[(2.8) \quad \int_{\Omega} f \, dx = 0.\]
and if for every function $h$ belonging to $W^{1,\infty}(\mathbb{R})$ with compact support and for every $\varphi \in L^\infty(\Omega) \cap W^{1,p}(\Omega)$, we have

\begin{equation}
(2.14) \quad \int_\Omega h(u) a(x, \nabla u) \nabla \varphi \, dx + \int_\Omega h'(u) a(x, \nabla u) \nabla u \varphi \, dx \\
+ \int_\Omega h(u) \Phi(x, u) \nabla \varphi \, dx + \int_\Omega h'(u) \Phi(x, u) \nabla u \varphi \, dx = \int_\Omega f \varphi h(u) \, dx.
\end{equation}

**Remark 2.3.** A renormalized solution is not in general an $L^1_{loc}(\Omega)$-function and therefore it has not a distributional gradient. Condition (2.12) allows to define a generalized gradient of $u$ according to Lemma 2.1 of [7], which asserts the existence of a unique measurable function $v$ defined in $\Omega$ such that $\nabla T_k(u) = \chi_{\{|u|<k\}} v$ a.e. in $\Omega$, $\forall k > 0$. This function $v$ is the generalized gradient of $u$ and it is denoted by $\nabla u$.

Equality (2.14) is formally obtained by using in (2.1) the test function $\varphi h(u)$ and by taking into account Neumann boundary conditions. Actually in a standard way one can check that every term in (2.14) is well-defined under the structural assumptions on the elliptic operator.

Let us recall Theorem 4.1 of [8]; under assumptions (2.2)-(2.8) there exists at least one renormalized solution $u$ having null median of problem (2.1). Moreover any renormalized solution to (2.1) verifies the following proposition

**Proposition 2.4.** Under the assumptions (2.2)-(2.8), if $u$ denotes any renormalized solution to problem (2.1), then

\begin{equation}
(2.15) \quad \lim_{n \to +\infty} \frac{1}{n} \int_\Omega |\Phi(x, u)| |\nabla T_n(u)| \, dx = 0,
\end{equation}

\begin{equation}
(2.16) \quad \int_\Omega \frac{|\nabla u|^p}{(1 + |u|)^{1+m}} \, dx \leq C, \quad \forall m > 0,
\end{equation}

where $C$ is a positive constant depending only on $m$, $f$, $\Omega$, $\alpha$ and $\Phi$

\begin{equation}
(2.17) \quad |u|^{p-1} \in L^q(\Omega), \forall 1 < q < \frac{N}{N-p},
\end{equation}

\begin{equation}
(2.18) \quad |\nabla u|^{p-1} \in L^q(\Omega), \forall 1 < q < \frac{N}{N-1}.
\end{equation}

**Sketch of the proof.** For the proof of (2.15) see Remark 2.4 of [8]. The estimate (2.16) is related to the Boccardo-Gallouët estimates [11], and it is obtained through a usual process. Indeed since $m > 0$,
\[
\int_0^r \frac{ds}{(1 + |s|)^{1+m}} \in L^\infty(\mathbb{R}) \cap C^1(\mathbb{R}).
\]
Defining \( h_n \) by
\[
(2.19) \quad h_n(s) = \begin{cases} 
0 & \text{if } |s| > 2n, \\
\frac{2n - |s|}{n} & \text{if } n < |s| \leq 2n, \\
1 & \text{if } |s| \leq n,
\end{cases}
\]
we can use the renormalized formulation (2.14) with \( h = h_n \) and \( \varphi = \int_0^{T_{2n(u)}} \frac{ds}{(1 + |s|)^{1+m}} \). In view of (2.13) and (2.15), the growth condition (2.5) on \( \Phi \) allows one to pass to the limit as \( n \to +\infty \) and to obtain (2.16).

As far as (2.17) and (2.18) are concerned, it is sufficient to observe that (2.12), (2.16) and Poincaré-Wirtinger inequality imply (through an approximation process) that \( \int_0^u \frac{ds}{(1 + |s|)^{1+m}} \in W^{1,p}(\Omega) \). Then Sobolev embedding Theorem leads to
\[
\forall m > 0, \ |u|^{\frac{p - (1+m)}{p}} \in L^{\frac{Np}{N - p}}(\Omega)
\]
which is equivalent to
\[
|u|^{p-1} \in L^q(\Omega), \ \forall \ 1 \leq q < \frac{N}{N - p}.
\]
Using again that \( \int_0^u \frac{ds}{(1 + |s|)^{1+m}} \in W^{1,p}(\Omega) \), (2.17) and Hölder inequality allow one to deduce (2.18).

3. Uniqueness results for weak solution

In this section we assume that the right-hand side \( f \) is an element of the dual space \( L^{(p')'}(\Omega) \). In [8] an existence result for weak solution to problem (2.1) having null median has been proved. Such a weak solution \( u \) is a function such that
\[
\int\Omega a(x, \nabla u) \nabla vdx + \int\Omega \Phi(x, u) \nabla vdx = \int\Omega fvdx,
\]
for any \( v \in W^{1,p}(\Omega) \).

In this section we assume a suitable growth condition on \( \Phi \), that is a bound on \( \tau \) in (2.7) is assumed and the following assumption on the datum is made
\[
(3.1) \quad f \in L^{(p')'}(\Omega).
\]
Now we prove two uniqueness results depending on the values of $p$:

**Theorem 3.1.** Let $1 < p < 2$. Assume that $(2.2)$–$(2.7)$ with

\[ \tau \leq p - 1 \]

and $(2.8)$, $(3.1)$ hold. If $u, v$ are two weak solutions to problem $(2.1)$ having $\text{med}(u) = \text{med}(v) = 0$, then $u = v$ a.e. in $\Omega$.

**Theorem 3.2.** Let $p \geq 2$. Assume that $(2.2)$–$(2.7)$ with

\[ \tau \leq \frac{Np}{N - p} \left( \frac{1}{2} - \frac{1}{t} \right), \]

\[ t \geq \max \left\{ 2, \frac{N}{p - 1} \right\} \]

and $(2.8)$, $(3.1)$ hold. If $u, v$ are two weak solutions to problem $(2.1)$ having $\text{med}(u) = \text{med}(v) = 0$, then $u = v$ a.e. in $\Omega$.

**Remark 3.3.** We explicitly observe that if $2 \leq p \leq \frac{N+2}{2}$, we have uniqueness results under the assumption that $c$ belongs to $L^{\frac{N}{N-1}}(\Omega)$ assumption which guarantees the existence of a solution. If $p > \frac{N+2}{2}$ the uniqueness result holds if $c$ belongs to $L^2(\Omega)$, which means that uniqueness result holds under a stronger assumption on the summability of $c$.

**Remark 3.4.** Let us observe that the bounds on $\tau$ in the two theorems overlaps when $p = 2$.

**Proof of Theorem 3.1.** Since for every fixed $k > 0$, $T_k(u - v) \in W^{1,p}(\Omega)$, it can be used as test function in the equation satisfied by $u$ and in the equation satisfied by $v$. Then by subtracting the two equations, we get

\[ \int_\Omega (a(x, \nabla u) - a(x, \nabla v)) \cdot \nabla T_k(u - v) \, dx \]

\[ + \int_\Omega (\Phi(x, u) - \Phi(x, v)) \cdot \nabla T_k(u - v) \, dx = 0. \]

We proceed by dividing the proof by steps.

**Step 1.** We prove that

\[ \lim_{k \to 0} \frac{1}{k^p} \int_\Omega |\nabla T_k(u - v)|^p \, dx = 0. \]
By the assumptions on the strong monotonicity on the operator (2.4) and the local Lipschitz condition on $\Phi$ (2.7) with $\tau$ which satisfies (3.2), we get

\begin{equation}
\beta \int_{\Omega} \frac{|\nabla T_k(u - v)|^2}{(|\nabla u| + |\nabla v|)^{2-p}} \, dx 
\leq k \int_{\Omega} c(x)(1 + |u| + |v|)^\tau |\nabla T_k(u - v)| \, dx.
\end{equation}

The assumption on $\tau$ assures that the right-hand side of the previous inequality is finite. Moreover by Hölder inequality and assumption on $\tau$, we obtain

\begin{equation}
\beta \int_{\Omega} \frac{|\nabla T_k(u - v)|^2}{(|\nabla u| + |\nabla v|)^{2-p}} \, dx 
\leq k \left( \int_{\{0 < |u - v| < k\}} c(x)^2 (1 + |u| + |v|)^{2\tau} (|\nabla u| + |\nabla v|)^{2-p} \, dx \right)^{\frac{1}{2}} 
\times \left( \int_{\Omega} \frac{|\nabla T_k(u - v)|^2}{(|\nabla u| + |\nabla v|)^{2-p}} \, dx \right)^{\frac{1}{2}}
\end{equation}

i.e.

\begin{equation}
\frac{\beta^2}{k^2} \int_{\Omega} \frac{|\nabla T_k(u - v)|^2}{(|\nabla u| + |\nabla v|)^{2-p}} \, dx 
\leq \int_{\{0 < |u - v| < k\}} c(x)^2 (1 + |u| + |v|)^{2\tau} (|\nabla u| + |\nabla v|)^{2-p} \, dx.
\end{equation}

Since $\tau \leq p - 1 = (1 - \frac{1}{p} - \frac{p-1}{N}) \frac{N_p}{N-p}$, Hölder inequality assures that the integral in the right-hand side is finite.

Since $\chi_{\{0 < |u - v| < k\}}$ tends to 0 a.e. in $\Omega$ as $k$ goes to 0, this implies

\begin{equation}
\lim_{k \to 0} \frac{1}{k^2} \int_{\Omega} \frac{|\nabla T_k(u - v)|^2}{(|\nabla u| + |\nabla v|)^{2-p}} \, dx = 0.
\end{equation}

Moreover by Hölder inequality we get

\begin{equation}
\frac{1}{k^p} \int_{\Omega} |\nabla T_k(u - v)|^p \, dx 
\leq \left( \frac{1}{k^2} \int_{\Omega} \frac{|\nabla T_k(u - v)|^2}{(|\nabla u| + |\nabla v|)^{2-p}} \, dx \right)^{\frac{p}{2}} \left( \int_{\Omega} (|\nabla u| + |\nabla v|)^p \, dx \right)^{1-\frac{p}{2}}
\end{equation}

which implies (3.6) by (3.10).
Step 2. We prove that either

\[
\begin{cases}
  u = v & \text{a.e. in } \Omega, \\
  u < v & \text{a.e. in } \Omega, \\
  u > v & \text{a.e. in } \Omega.
\end{cases}
\]

Since \( \frac{T_k(u-v)}{k} \) belongs to \( W^{1,p}(\Omega) \) Poincaré-Wirtinger inequality yields

\[
\int_\Omega \left| \frac{T_k(u-v)}{k} - \text{med} \left( \frac{T_k(u-v)}{k} \right) \right|^p \, dx 
\leq C \int_\Omega \left| \nabla T_k(u-v) \right|^p \, dx.
\]

Therefore, by Step 1, we deduce that

\[
\lim_{k \to 0} \int_\Omega \left| \frac{T_k(u-v)}{k} - \text{med} \left( \frac{T_k(u-v)}{k} \right) \right|^p \, dx = 0.
\]

Since \( \left| \frac{T_k(u-v)}{k} \right| \leq 1 \), we obtain

\[
\left| \text{med} \left( \frac{T_k(u-v)}{k} \right) \right| \leq 1, \ k > 0
\]

and, up to a subsequence, by (3.13)

\[
\lim_{k \to 0} \text{med} \left( \frac{T_k(u-v)}{k} \right) = \gamma
\]

for a suitable constant \( \gamma \in \mathbb{R}, \ |\gamma| \leq 1 \). On the other hand, we have

\[
\lim_{k \to 0} \frac{T_k(u-v)}{k} = \text{sign} \ (u-v).
\]

Therefore, up to subsequence, by (3.13) we get

\[
\int_\Omega |\text{sign} \ (u-v) - \gamma|^p \, dx = 0
\]

which implies

\[
\gamma = 0 \quad \text{or} \quad \gamma = -1 \quad \text{or} \quad \gamma = 1.
\]

This means that either

\[
\begin{cases}
  u = v & \text{a.e. in } \Omega, \\
  u < v & \text{a.e. in } \Omega, \\
  u > v & \text{a.e. in } \Omega.
\end{cases}
\]

Step 3. We prove that \( u < v, \) a.e. in \( \Omega \) or \( u > v, \) a.e. in \( \Omega \) can not occur.
We assume that
\[ u > v, \quad \text{a.e. in } \Omega \]
and we prove that this yields a contradiction. The same arguments prove that \( u < v \) a.e. in \( \Omega \) cannot be verified.

Since \( \text{med}(v) = 0 \), \( \text{meas}\{x \in \Omega : v(x) < 0\} \leq \frac{\text{meas}(\Omega)}{2} \), then
\[ (3.15) \quad \text{meas}\{x \in \Omega : v(x) \geq 0\} \geq \frac{\text{meas}(\Omega)}{2}. \]

On the other hand, we have
\[ \{x \in \Omega : u(x) > 0\} \]
\[ = \{x \in \Omega : u(x) > 0, v(x) \geq 0\} \cup \{x \in \Omega : u(x) > 0, v(x) < 0\}. \]

Since we assume \((3.14)\), then we deduce
\[ \{x \in \Omega : u(x) > 0, v(x) \geq 0\} = \{x \in \Omega : v(x) \geq 0\} \]
Thus means that “\( u \) and \( v \) have the same sign”.

Now let us consider the test function
\[ (3.16) \quad w_{k, \delta} = \frac{T_k(u - v)}{k} \left( \frac{T_\delta(u^+)}{\delta} - \frac{T_\delta(v^-)}{\delta} \right), \]
for fixed \( k > 0, \delta > 0 \), where
\[ u^+ = \max\{0, u\}, \quad v^- = \max\{0, -v\}. \]

Since \( T_k(u - v) > 0 \) a.e. in \( \Omega \), one can verify that
\[ \{x \in \Omega : w_{k, \delta}(x) > 0\} = \{x \in \Omega : u(x) > 0\} \]
and
\[ \{x \in \Omega : w_{k, \delta}(x) < 0\} = \{x \in \Omega : v(x) < 0\}. \]

Moreover \( T_\delta(u^+), T_\delta(v^-) \in W^{1,p}(\Omega) \) and hence, since \( \text{med}(u), \text{med}(v) = 0 \), we conclude that
\[ \text{meas}\{x \in \Omega : w_{k, \delta}(x) > 0\} \leq \frac{\text{meas}(\Omega)}{2}, \]
meas\{x \in \Omega : w_{k,\delta}(x) < 0\} \leq \frac{\text{meas}(\Omega)}{2},

this means

\text{med}(w_{k,\delta}) = 0.

Therefore by Poincaré-Wirtinger inequality we deduce

\int_{\Omega} |w_{k,\delta}|^p \, dx \leq C \int_{\Omega} |\nabla w_{k,\delta}|^p \, dx.

We now evaluate the gradient of $w_{k,\delta}$,

\begin{equation}
\nabla w_{k,\delta} = \frac{\nabla T_k(u - v)}{k} \left( \frac{\delta}{\delta} T_\delta(u^+) - \frac{\delta}{\delta} T_\delta(v^-) \right)
+ \frac{T_k(u - v)}{k} \left( \frac{\nabla u}{\delta} \chi_{\{0 < u < \delta\}} + \frac{\nabla v}{\delta} \chi_{\{-\delta < v < 0\}} \right) \quad \text{a.e. in } \Omega.
\end{equation}

Since $u$ and $v$ “have the same sign”, then, for every fixed $k > 0$, it results

\begin{align*}
0 < \frac{T_k(u - v)}{k\delta} \chi_{\{0 < u < \delta\}} &\leq \frac{1}{k} \chi_{\{0 < u < \delta\}}, \\
0 < \frac{T_k(u - v)}{k\delta} \chi_{\{-\delta < v < 0\}} &\leq \frac{1}{k} \chi_{\{-\delta < v < 0\}},
\end{align*}

then for fixed $k > 0$, we have

\begin{align*}
\lim_{\delta \to 0} \frac{T_k(u - v)}{k\delta} \chi_{\{0 < u < \delta\}} &\to 0 \quad \text{a.e. in } \Omega, \\
\lim_{\delta \to 0} \frac{T_k(u - v)}{k\delta} \chi_{\{-\delta < v < 0\}} &\to 0 \quad \text{a.e. in } \Omega.
\end{align*}

Moreover we have also

\begin{align*}
\left| \frac{T_k(u - v)}{k\delta} \nabla u \chi_{\{0 < u < \delta\}} \right| &\leq \frac{1}{k} |\nabla u| \chi_{\{0 < u < \delta\}}, \\
\left| \frac{T_k(u - v)}{k\delta} \nabla v \chi_{\{-\delta < v < 0\}} \right| &\leq \frac{1}{k} |\nabla v| \chi_{\{-\delta < v < 0\}},
\end{align*}

and since $|\nabla u|, |\nabla v| \in L^p(\Omega)$, we can apply Lebesgue dominated convergence Theorem, i.e.

\begin{equation}
\lim_{\delta \to 0} \int_{\Omega} |\nabla w_{k,\delta}|^p \, dx = \int_{\Omega} \left| \frac{\nabla T_k(u - v)}{k} \chi_{\{u > 0\}} - \chi_{\{v < 0\}} \right|^p \, dx.
\end{equation}

Since

\begin{equation}
\int_{\Omega} \left| \frac{\nabla T_k(u - v)}{k} \chi_{\{u > 0\}} - \chi_{\{v < 0\}} \right|^p \, dx \leq \int_{\Omega} \left| \frac{\nabla T_k(u - v)}{k} \right|^p \, dx,
\end{equation}
by Step 1, we conclude that

$$\lim_{k \to 0} \lim_{\delta \to 0} \int_\Omega |\nabla w_{k,\delta}|^p \, dx = 0.$$ 

Now we can pass to the limit in (3.17) as $\delta \to 0$ first and then as $k \to 0$ and we get

$$\int_\Omega |\text{sign} \ (u - v) \left( \chi_{\{ u > 0 \}} - \chi_{\{ v < 0 \}} \right) |^p \, dx = \int_\Omega |\text{sign}(u)|^p \, dx = 0.$$

We deduce that $\chi_{\{ u > 0 \}} = \chi_{\{ v < 0 \}}$ a.e. in $\Omega$; this yields a contradiction since we have proved that $u$ and $v$ have the same sign.

The same arguments yield that we can not have $u < v$ a.e. in $\Omega$. The conclusion follows. \quad \square

**Proof of Theorem 3.2.** As in the previous proof we arrive to equality (3.5) and we divide the proof by 3 steps.

**Step 1.** We prove that

$$\lim_{k \to 0} \frac{1}{k^2} \int_\Omega |\nabla T_k(u - v)|^2 \, dx = 0.$$ 

By the assumptions on the strong monotonicity on the operator (2.4) and the local Lipschitz condition on $\Phi$ (2.7) with $\tau$ which satisfies (3.3), we get

$$\beta \int_\Omega (1 + |\nabla u| + |\nabla v|)^{p-2} |\nabla T_k(u - v)|^2 \, dx$$

$$\leq k \int_\Omega c(x) (1 + |u| + |v|)^\tau |\nabla T_k(u - v)| \, dx.$$ 

Since $p \geq 2$, $T_k(u - v)$ belongs to $W^{1,2}(\Omega)$. Then by H"older inequality and assumption on $\tau$, we obtain

$$\beta \int_\Omega |\nabla T_k(u - v)|^2 \, dx$$

$$\leq k \|c\|_{L^1(\{0 < |u-v| < k\})} \|1 + |u| + |v|\|_{L^p} \|\nabla T_k(u - v)\|_{L^2} \, dx,$$

i.e.

$$\frac{\beta^2}{k^2} \int_\Omega |\nabla T_k(u - v)|^2 \, dx \leq \|c\|_{L^1(\{0 < |u-v| < k\})}^2 \|1 + |u| + |v|\|_{L^p}^{2\tau} \, dx.$$ 

Since $\chi_{\{x: 0 < |u-v| < k\}} \to 0$ a.e. in $\Omega$, Lebesgue dominated convergence theorem implies that (3.19) holds.
Step 2. We prove that either
\[
\begin{aligned}
&\left\{\begin{array}{l}
u = v \quad \text{a.e. in } \Omega, \\
u < v \quad \text{a.e. in } \Omega, \\
u > v \quad \text{a.e. in } \Omega.
\end{array}\right.
\end{aligned}
\]

By Poincaré-Wirtinger inequality, we get
\[
\int_{\Omega} \left| \frac{T_k(u-v)}{k} - \text{med} \left( \frac{T_k(u-v)}{k} \right) \right|^2 \, dx 
\leq C \int_{\Omega} \left| \nabla T_k(u-v) \right|^2 \, dx.
\]

Therefore, by Step 1. we deduce that
\[
\lim_{k \to 0} \int_{\Omega} \left| \frac{T_k(u-v)}{k} - \text{med} \left( \frac{T_k(u-v)}{k} \right) \right|^2 \, dx = 0
\]
\[(3.24)\]

Since \( \left| \frac{T_k(u-v)}{k} \right| \leq 1 \), we obtain
\[
\left| \text{med} \left( \frac{T_k(u-v)}{k} \right) \right| \leq 1,
\]
and, up to a subsequence,
\[
\lim_{k \to 0} \text{med} \left( \frac{T_k(u-v)}{k} \right) = \gamma
\]
for a suitable constant \( \gamma \in \mathbb{R}, |\gamma| \leq 1 \). On the other hand, we have
\[
\lim_{k \to 0} \frac{T_k(u-v)}{k} = \text{sign} \,(u-v),
\]
Therefore, up to subsequence, we get
\[
\int_{\Omega} \left| \text{sign} \,(u-v) - \gamma \right|^2 \, dx = 0
\]
which implies
\[
\gamma = 0 \quad \text{or} \quad \gamma = -1 \quad \text{or} \quad \gamma = 1.
\]
This means that either
\( u = v \), a.e. in \( \Omega \) or \( u < v \), a.e. in \( \Omega \) or \( u > v \), a.e. in \( \Omega \).

Step 3. Arguing as in Step 3 of the previous theorem, we prove that the last two possibilities can not occur. Then conclusion follows. \( \Box \)
Remark 3.5. In [8] we established the existence of a weak solution when \( a(x, \xi) \) is replaced by a Leray-Lions operator \( a(x, r, \xi) \) which depends on \( x, r \) and \( \xi \) and verifies the standard conditions (see [25]). In the Dirichlet case and \( 1 < p \leq 2 \) it is well known (see [13] [15]) that under suitable assumptions on \( a(x, r, \xi) \) the weak solution is unique.

In view of the proofs of Theorem 3.1 and Theorem 3.2 it is possible to obtain the uniqueness of the weak solution having null median of the problem

\[
\begin{aligned}
- \text{div} \left( a(x, u, \nabla u) + \Phi(x, u) \right) &= f & \text{in } \Omega, \\
(a(x, u, \nabla u) + \Phi(x, u)) \cdot n &= 0 & \text{on } \partial \Omega.
\end{aligned}
\]  

(3.25)

If we assume that \( a(x, r, \xi) \) is a Carathéodory function which verifies

\[
|a(x, s, \xi) - a(x, s, \eta)| \geq \alpha|\xi - \eta|^p, \quad \alpha > 0,
\]  

(3.26)

\[
|a(x, s, \xi)| \leq c_1(|\xi|^{p-1} + |s|^{p-1} + a_0(x)),
\]  

(3.27)

\[
a_0 \in L^{p'}(\Omega), \quad a_0 \geq 0,
\]  

(3.28)

and moreover \( a(x, r, \xi) \) satisfies a Lipschitz condition with respect to \( r \)

\[
|a(x, s, \xi) - a(x, r, \xi)| \leq c_2|s - r|(|\xi|^{p-1} + |s|^{p-1} + |r|^{p-1} + h(x)),
\]  

(3.29)

\[
c_2 > 0, \quad h \in L^{p'}(\Omega), \quad h \geq 0,
\]

and for almost every \( x \in \Omega, s \in \mathbb{R} \) and for every \( \xi, \eta \in \mathbb{R}^N \), then Theorem 3.1 and Theorem 3.2 hold true. Indeed the methods developped in [13] allow one to prove Step 1 in Theorem 3.1 namely

\[
\lim_{k \to 0} \frac{1}{k^p} \int_{\Omega} |\nabla T_k(u - v)|^p \, dx = 0.
\]

and Step 1 in Theorem 3.2 namely

\[
\lim_{k \to 0} \frac{1}{k^2} \int_{\Omega} |\nabla T_k(u - v)|^2 \, dx = 0.
\]

In both cases the Step 2 and Step 3 remain unchanged.

Remark 3.6. In [8] and in the present paper we have chosen to deal with solutions to (2.1) with null median value instead of null mean value. As explained in Introduction this choice allows one to consider solution to (2.1) for \( f \in L^1(\Omega) \) even if the solution \( u \) does not belong
to $L^1(\Omega)$. When $f \in L^{(p^*)'}(\Omega)$ a simply examination of the proof of [8] leads to the existence of solutions to (2.1) such that $\int_\Omega u \, dx = 0$. Assuming that (2.2)–(2.7) are in force similar arguments to the one developed in the proof of Theorem 3.1 and Theorem 3.2 yield the uniqueness of solution to (2.1) having a null mean value. Let us explain briefly the case $p = 2$. Step 1 remains unchanged so that if $u$ and $v$ are two solutions of (2.1) then we have
\[
\lim_{k \to 0} \frac{1}{k^2} \int_\Omega |\nabla T_k(u - v)|^2 \, dx = 0.
\]
Poincaré-Wirtinger inequality leads to
\[
\lim_{k \to 0} \int_\Omega \left| \frac{T_k(u - v)}{k} - \frac{1}{|\Omega|} \int_\Omega \frac{T_k(u - v)}{k} \right|^2 \, dy = 0.
\]
so that, up to subsequence, there exists $\gamma \in [-1, 1]$ such that
\[
\int_\Omega |\text{sign}(u - v) - \gamma|^2 \, dx = 0.
\]
As in Step 2
\[
\gamma = 0 \quad \text{or} \quad \gamma = -1 \quad \text{or} \quad \gamma = 1
\]
and
\[
\begin{cases}
  u = v & \text{a.e. in } \Omega, \\
  u < v & \text{a.e. in } \Omega, \\
  u > v & \text{a.e. in } \Omega.
\end{cases}
\]
We now show that $u < v$ a.e. in $\Omega$ or $u > v$ a.e. in $\Omega$ can not occur. The method is similar to Step 3 of the proof of Theorem 3.1:
\[
w_{k,\delta} = \frac{T_k(u - v)}{k} \left( \frac{T_\delta(u^+)}{\delta} - \frac{T_\delta(v^-)}{\delta} \right),
\]
belongs to $H^1(\Omega)$ while
\[
\lim_{k \to 0} \lim_{\delta \to 0} \|\nabla w_{k,\delta}\|_{L^2(\Omega)} = 0.
\]
Poincaré-Wirtinger inequality yields
\[
\lim_{k \to 0} \lim_{\delta \to 0} \int_\Omega \left| w_{k,\delta} - \frac{1}{|\Omega|} \int_\Omega w_{k,\delta} \right|^2 \, dx = 0.
\]
In the case $u > v$ a.e. in $\Omega$, the Lebesque dominated Theorem allows one to conclude that
\[
\int_\Omega \left| \text{sign}(u) - \frac{1}{|\Omega|} \int_\Omega \text{sign}(u) \right|^2 \, dx = 0,
\]
and then \( u \) has a constant sign. Recalling that \( \int_{\Omega} u \, dx = \int_{\Omega} v \, dx = 0 \) gives a contradiction. Therefore \( u = v \) a.e. in \( \Omega \).

### 4. Uniqueness result for renormalized solution

In this section we prove the uniqueness of the renormalized solution to problem (2.1), when the following assumption on datum is made

\[
(4.1) \quad f \in L^1(\Omega).
\]

As in Section 3 we state two uniqueness theorems depending on the values of \( p \):

**Theorem 4.1.** Let \( 1 < p < 2 \). Assume that (2.2)–(2.7) with

\[
(4.2) \quad \tau \leq p - \frac{3}{2} + \left[ \frac{p-1}{N} - \frac{1}{t} \right] \frac{N(p-1)}{N-p}
\]

and (2.8), (4.1) hold. If \( u, v \) are two renormalized solutions to problem (2.1) having \( \text{med}(u) = \text{med}(v) = 0 \), then \( u = v \) a.e. in \( \Omega \).

**Theorem 4.2.** Let \( p \geq 2 \). Assume that (2.2)–(2.7) with

\[
(4.3) \quad \tau \leq \frac{N(p-1)}{N-p} \left( \frac{1}{2} - \frac{1}{t} \right)
\]

\[
(4.4) \quad t \geq \max \left\{ 2, \frac{N}{p-1} \right\}
\]

and (2.8), (4.1) hold. If \( u, v \) are two renormalized solutions to problem (2.1) having \( \text{med}(u) = \text{med}(v) = 0 \), then \( u = v \) a.e. in \( \Omega \).

**Proof of Theorem 4.1.** Let \( u \) and \( v \) be two renormalized solutions to (2.1). Let \( h_n \) defined by (2.19). Since for any \( k > 0 \), \( h_n(u)T_k(u - v) = h_n(v)T_k(T_{2n}(u) - T_{2n+k}(u)) \in L^\infty(\Omega) \cap W^{1,p}(\Omega) \), we can use \( h = h_n(u) \) and \( \varphi = h_n(v)T_k(u - v) \) in (2.14) written in \( u \), and we can use \( h = h_n(v) \) and \( \varphi = h_n(u)T_k(u - v) \) in (2.14) written in \( v \). By substracting the two equations, we get

\[
\int_{\Omega} h_n(u)h_n(v)(a(x, \nabla u) - a(x, \nabla v)) \cdot \nabla T_k(u - v) \, dx
\]

\[
+ \int_{\Omega} h_n(u)h_n(v)(\Phi(x, u) - \Phi(x, v)) \cdot \nabla T_k(u - v) \, dx
\]

\[
+ \int_{\Omega} h'_n(u)h_n(v)T_k(u - v)(a(x, \nabla u) + \Phi(x, u) - a(x, \nabla v) - \Phi(x, v)) \cdot \nabla u \, dx
\]

\[
+ \int_{\Omega} h_n(u)h'_n(v)T_k(u - v)(a(x, \nabla u) + \Phi(x, u) - a(x, \nabla v) - \Phi(x, v)) \cdot \nabla v \, dx = 0.
\]
We proceed by dividing the proof into 3 steps.

**Step 1.** By passing to the limit in (4.5) first as \( n \to +\infty \), then as \( k \to 0 \) this step is devoted to prove that

\[
\lim_{k \to 0} \frac{1}{k^2} \int_{\Omega} \left( \frac{|\nabla T_k(u - v)|^2}{(|\nabla u| + |\nabla v|)^{2-p}} \right) dx = 0.
\]

We first study the behaviour of the last two integrals in (4.5) as \( n \) goes to \(+\infty\) by showing

\[
\lim_{n \to +\infty} \int_{\Omega} h_n'(u) h_n(v) T_k(u - v) (a(x, \nabla u) + \Phi(x, u) - a(x, \nabla v) - \Phi(x, v)) \cdot \nabla u dx = 0
\]

and by symmetry with respect to \( u \) and \( v \)

\[
\lim_{n \to +\infty} \int_{\Omega} h_n'(v) h_n(u) T_k(u - v) (a(x, \nabla u) + \Phi(x, u) - a(x, \nabla v) - \Phi(x, v)) \cdot \nabla v dx = 0.
\]

By (2.13) of Definition 2.2 and (2.15) of Proposition 2.4, we get

\[
\lim_{n \to +\infty} \int_{\Omega} h_n'(u) h_n(v) T_k(u - v) a(x, \nabla u) \cdot \nabla u dx = 0,
\]

(4.10) \[
\lim_{n \to +\infty} \int_{\Omega} h_n'(u) h_n(v) T_k(u - v) \Phi(x, u) \cdot \nabla u dx = 0.
\]

By assumption (2.3) and Hölder inequality we have

\[
\left| \int_{\Omega} h_n'(u) h_n(v) T_k(u - v) a(x, \nabla v) \cdot \nabla u dx \right| \leq \frac{ck}{n} \left( \int_{\{|u| \leq 2n\}} (|a_0(x)| + |\nabla v|^{p-1}) \frac{1}{|\nabla v|} dx \right) \left( \int_{\{|u| \leq 2n\}} |\nabla u|^p dx \right)^{\frac{1}{p}}.
\]

Using (2.2) and (2.13) we deduce that

\[
\lim_{n \to +\infty} \frac{1}{n} \int_{\{|u| \leq 2n\}} |\nabla u|^p dx = 0.
\]

Therefore recalling that \( a_0 \in L^{p'}(\Omega) \) we conclude that

\[
\lim_{n \to +\infty} \left| \int_{\Omega} h_n'(u) h_n(v) T_k(u - v) a(x, \nabla v) \cdot \nabla u dx \right| = 0.
\]
To prove that (4.7) holds it remains to control \( \int_{\Omega} h'_n(u) h_n(v) T_k(u - v) \Phi(x, v) \cdot \nabla u \, dx \). By assumption (2.5) and Hölder inequality we have
\[
\left| \int_{\Omega} h'_n(u) h_n(v) T_k(u - v) \Phi(x, v) \cdot \nabla u \, dx \right| \\
\leq k \left( \frac{1}{n} \int_{\{|v| \leq 2n\}} |c(x)|^{\frac{p}{p-1}} (1 + |v|)^p \, dx \right)^{\frac{p-1}{p}} \left( \frac{1}{n} \int_{\{|u| \leq 2n\}} |\nabla u|^p \, dx \right)^{\frac{1}{p}}.
\]
Since \( c \in L^t(\Omega) \) with \( t \geq N/(p-1) \) (see Assumption (2.6)) we get
\[
\int_{\{|v| \leq 2n\}} |c(x)|^{\frac{p}{p-1}} (1 + |v|)^p \leq \left( \int_{\Omega} |c|^{N/(p-1)} \, dx \right)^{p/N} \left( 1 + T_{2n}(v) \right)^p_{L^p(\Omega)}
\]
and Poincaré-Wirtinger inequality leads to
\[
\int_{\{|v| \leq 2n\}} |c(x)|^{\frac{p}{p-1}} (1 + |v|)^p \leq C \left( \int_{\Omega} |c|^{N/(p-1)} \, dx \right)^{p/N} \left( 1 + \int_{\Omega} |\nabla T_{2n}(v)|^p \, dx \right),
\]
where \( C > 0 \) is independent of \( n \) and \( k \). It follows that
\[
\left| \int_{\Omega} h'_n(u) h_n(v) T_k(u - v) \Phi(x, v) \cdot \nabla u \, dx \right| \leq C k \| c \|_{L^{N/(p-1)}(\Omega)} \left( 1 + \int_{\Omega} |\nabla u|^p \, dx \right)^{\frac{p-1}{p}} \left( \frac{1}{n} \int_{\{|u| \leq 2n\}} |\nabla u|^p \, dx \right)^{\frac{1}{p}}.
\]
Therefore (4.11) leads to
\[
\lim_{n \to +\infty} \left| \int_{\Omega} h'_n(u) h_n(v) T_k(u - v) \Phi(x, v) \cdot \nabla u \, dx \right| = 0,
\]
and then (4.7) holds. We observe that (4.8) is obtained by analogous argument.

Then by (4.5), (4.7), (4.8), using the assumptions on the strong monotonicity on the operator (2.4), the local Lipschitz condition on \( \Phi \) (2.7) with \( \tau \) which satisfies (4.2) and Young inequality we get
\[
\beta \int_{\Omega} h_n(u) h_n(v) \frac{|\nabla T_k(u - v)|^2}{(|\nabla u| + |\nabla v|)^{2-\tau}} \, dx \leq 2\omega_k(n)
\]
\[
+ \frac{2k^2}{\beta} \int_{\{0<|u-v|\leq k\}} h_n(u) h_n(v) |c(x)|^2 (1 + |u| + |v|)^{2\tau} (|\nabla u| + |\nabla v|)^{2-\tau} \, dx,
\]
where \( \lim_n \omega_k(n) = 0 \).

We now prove that
\[
|c(x)|^2 (1 + |u| + |v|)^{2\tau} (|\nabla u| + |\nabla v|)^{2-\tau} \in L^1(\Omega),
\]
so that we can pass to the limit in (4.14) as \( n \to +\infty \). By Hölder inequality we get

\[
\int_\Omega h_n(u)h_n(v)|c(x)|^2(1 + |u| + |v|)^{2\tau}(|\nabla u| + |\nabla v|)^{2-p} \, dx
\]

\[
\leq \left( \int_{\{|u|<2n, |v|<2n\}} h_n(u)h_n(v)|c(x)|^t \, dx \right)^{\frac{t}{2}}
\times \left( \int_{\{|u|<2n, |v|<2n\}} h_n(u)h_n(v)(1 + |u| + |v|)^{\nu} \, dx \right)^{\frac{2\nu}{\nu}}
\times \left( \int_{\{|u|<2n, |v|<2n\}} h_n(u)h_n(v)(|\nabla u| + |\nabla v|)^{\mu} \, dx \right)^{\frac{2-\mu}{\mu}}
\]

with

\[
\frac{1}{t} + \frac{2\tau}{\nu} + \frac{2-p}{\mu} \leq 1, \quad \nu < \frac{N(p-1)}{N-p}, \quad \mu < \frac{N(p-1)}{N-1},
\]

This choice is possible since (4.2) holds and in view of (2.17) and (2.18) of Proposition 2.4 we have

\[
(1 + |u| + |v|)^{\nu} \in L^1(\Omega), \quad (|\nabla u| + |\nabla v|)^{\mu} \in L^1(\Omega).
\]

Passing to the limit as \( n \) goes to \( +\infty \), assumption (2.6) on \( c \) and Fatou Lemma yield that

\[
|c(x)|^2(1 + |u| + |v|)^{2\tau}(|\nabla u| + |\nabla v|)^{2-p} \in L^1(\Omega).
\]

Then we can pass to the limit as \( n \to +\infty \) in (4.14), and dividing (4.14) by \( k^2 \) and using Fatou Lemma we get

\[
\frac{1}{k^2} \int_\Omega \frac{|\nabla T_k(u-v)|^2}{(|\nabla u| + |\nabla v|)^{2-p}} \, dx
\]

\[
\leq \frac{1}{\beta^2} \int_{\{|0|<|u-v|<k\}} |c(x)|^2(1 + |u| + |v|)^{2\tau}(|\nabla u| + |\nabla v|)^{2-p} \, dx.
\]

Recalling that \( \chi_{\{|0|<|u-v|<k\}} \) converges to 0 a.e. as \( k \) goes to zero, Lebesgue dominated Theorem and (4.15) allow one to conclude that (4.6) holds.

**Step 2.** We prove that either

\[
\begin{cases}
  u = v & \text{a.e. in } \Omega, \\
  u < v & \text{a.e. in } \Omega, \\
  u > v & \text{a.e. in } \Omega.
\end{cases}
\]
Observe that for $k < n$

$$h_n(u) \frac{T_k(u - v)}{k} = h_n(u) \frac{T_k(T_{3n}(u) - T_{3n}(v))}{k} \in L^\infty(\Omega) \cap W^{1,p}(\Omega).$$

Then by Poincaré-Wirtinger inequality, we get

$$\int_{\Omega} \left| h_n(u) \frac{T_k(u - v)}{k} - \text{med} \left( h_n(u) \frac{T_k(u - v)}{k} \right) \right|^p \, dx$$

$$\leq C \int_{\Omega} \left| \nabla \left( h_n(u) \frac{T_k(u - v)}{k} \right) \right|^p \, dx.$$

Let us evaluate the integral at the right-hand side. We show that it goes to zero first as $k \to 0$ and then as $n \to +\infty$.

Since

$$\nabla \left( h_n(u) \frac{T_k(u - v)}{k} \right) = h'_n(u) \nabla u \frac{T_k(u - v)}{k} + h_n(u) \frac{\nabla T_k(u - v)}{k} \quad \text{a.e. in } \Omega,$$

$$\left| \frac{T_k(u - v)}{k} \right| \leq 1 \text{ and } h'_n(u) \leq \frac{1}{n},$$

we get

$$\int_{\Omega} \left| \nabla \left( h_n(u) \frac{T_k(u - v)}{k} \right) \right|^p \, dx$$

$$\leq \frac{1}{n^p} \int_{\Omega} |\nabla T_{2n}(u)|^p \, dx + \frac{1}{k^p} \int_{\Omega} h_n(u)^p |\nabla T_k(u - v)|^p \, dx.$$  

Let us evaluate the second integral in the right hand side of (4.21). By H"{o}lder inequality we obtain

$$\frac{1}{k^p} \int_{\Omega} h_n(u)^p |\nabla T_k(u - v)|^p \, dx$$

$$\leq \left( \frac{1}{k^2} \int_{\Omega} \frac{|\nabla T_k(u - v)|^2}{(|\nabla u| + |\nabla v|)^{2-p}} \, dx \right)^{\frac{2}{2-p}} \left( \int_{\Omega} h_n(u)^{2p} \chi_{\{|u-v| < k\}}(|\nabla u| + |\nabla v|)^p \, dx \right)^{\frac{2-p}{2}}$$

$$\leq C \left( \frac{1}{k^2} \int_{\Omega} \frac{|\nabla T_k(u - v)|^2}{(|\nabla u| + |\nabla v|)^{2-p}} \, dx \right)^{\frac{2}{2-p}} \left( \int_{\Omega} (|\nabla T_{2n}(u)|^p + |\nabla T_{2n+k}(v)|^p) \, dx \right)^{\frac{2-p}{2}}.$$
that is, if $n$ is fixed,
\[
\frac{1}{k^p} \int_\Omega h_n(u)^p \left| \nabla T_k(u - v) \right|^p \, dx \leq C_n \left( \frac{1}{k^2} \int_\Omega \frac{\left| \nabla T_k(u - v) \right|^2}{\left| \nabla u \right| + \left| \nabla v \right|^{2-p}} \, dx \right)^{\frac{p}{2}} ,
\]
where $C_n > 0$ is a constant depending on $n$ (and independent of $k$). Therefore, by Step 1, we deduce that
\[
\lim_{k \to 0} \frac{1}{k^p} \int_\Omega h_n(u)^p \left| \nabla T_k(u - v) \right|^p \, dx = 0 .
\]
(4.22)

Since \( \left| \frac{T_k(u - v)}{k} \right| \) converges to \( \text{sign}(u - v) \) in \( L^\infty(\Omega) \) weak-\( * \), we deduce from (4.20) and (4.22) that for fixed $n$, as $k \to 0$
\[
\nabla \left( h_n(u) \frac{T_k(u - v)}{k} \right) \to h'_n(u) \nabla u \text{sign}(u - v) \, , \text{ in } (L^p(\Omega))^N.
\]

We now pass to the limit as $n \to +\infty$. By the definition of $h_n$ we have
\[
\int_\Omega \left| h'_n(u) \nabla u \right|^p \, dx \leq \frac{1}{n^p} \int_\Omega \left| \nabla T_{2n}(u) \right|^p \, dx
\]
so that (2.13) and (4.22) lead to
\[
\lim_{n \to +\infty} \lim_{k \to 0} \int_\Omega \left| \nabla \left( h_n(u) \frac{T_k(u - v)}{k} \right) \right|^p \, dx = 0.
\]

Therefore using (4.19), we deduce that
\[
\lim_{n \to +\infty} \lim_{k \to 0} \int_\Omega \left| h_n(u) \frac{T_k(u - v)}{k} - \text{med} \left( h_n(u) \frac{T_k(u - v)}{k} \right) \right|^p \, dx = 0.
\]
(4.23)

Since \( \left| h_n(u) \frac{T_k(u - v)}{k} \right| \leq 1 \), we obtain
\[
\left| \text{med} \left( h_n(u) \frac{T_k(u - v)}{k} \right) \right| \leq 1 , \, k > 0.
\]

It follows that, up to a subsequence
\[
\lim_{n \to +\infty} \lim_{k \to 0} \text{med} \left( h_n(u) \frac{T_k(u - v)}{k} \right) = \gamma .
\]
for a suitable constant $\gamma \in \mathbb{R}$, $|\gamma| \leq 1$.

On the other hand since $u$ is finite a.e. we have
\[
\lim_{k \to 0} h_n(u) \frac{T_k(u - v)}{k} = h_n(u) \text{sign}(u - v) , \, \text{ a.e. and } L^\infty(\Omega) \text{ weak-}* ,
\]
\[
\lim_{n \to +\infty} h_n(u) \text{sign}(u - v) = \text{sign}(u - v) , \, \text{ a.e. and } L^\infty(\Omega) \text{ weak-}*. 
\]
Then, up to subsequence, by (4.23) we get
\[ \int_{\Omega} |\text{sign } (u - v) - \gamma|^p \, dx = 0. \]
This implies
\[ \gamma = 0 \quad \text{or} \quad \gamma = -1 \quad \text{or} \quad \gamma = 1, \]
and means that either
\[ u = v, \ \text{a.e. in } \Omega \quad \text{or} \quad u < v, \ \text{a.e. in } \Omega \quad \text{or} \quad u > v, \ \text{a.e. in } \Omega. \]

Step 3. We prove that \( u < v, \ \text{a.e. in } \Omega \) or \( u > v, \ \text{a.e. in } \Omega \) can not occur.
We assume that
\[ u > v, \ \text{a.e. in } \Omega \] (4.24)
and we prove that this yields a contradiction.

The arguments used in Step 3 of Theorem 3.1 allow us to prove that

“\( u \) and \( v \) have the same sign”.

Let us consider the test function
\[ w_{n,k,\delta} = h_n(u) \frac{T_k(u - v)}{k} \left( \frac{T_\delta(u^+)}{\delta} - \frac{T_\delta(v^-)}{\delta} \right), \] (4.25)
for fixed \( n > 0, k > 0, \delta > 0 \), where
\[ u^+ = \max\{0, u\}, \quad v^- = \max\{0, -v\}. \]

Observe that, since for \( k < n \) \( h_n u \frac{T_k(u-v)}{k} \in L^\infty(\Omega) \cap W^{1,p}(\Omega) \) we have
\[ w_{n,k,\delta} \in L^\infty(\Omega) \cap W^{1,p}(\Omega). \]

We now evaluate the gradient of \( w_{n,k,\delta} \):
\[ \nabla w_{n,k,\delta} = \nabla \left( h_n(u) \frac{T_k(u - v)}{k} \left( \frac{T_\delta(u^+)}{\delta} - \frac{T_\delta(v^-)}{\delta} \right) \right) \]
\[ + h_n(u) \frac{T_k(u - v)}{k} \left( \frac{\nabla u}{\delta} \chi_{\{0 < u \leq \delta\}} - \frac{\nabla v}{\delta} \chi_{\{-\delta < v < 0\}} \right) \ \text{a.e. in } \Omega. \] (4.26)

and we study the limit as \( \delta \to 0, k \to 0 \) and then \( n \to +\infty \). We firstly show that \( \text{med}(w_{n,k,\delta}) = 0 \). Let \( \eta \) such that \( 0 < \eta < \frac{1}{2} \).

\[ \{ x \in \Omega : w_{n,k,\delta}(x) > \eta \} = \{ x \in \Omega : w_{n,k,\delta}(x) > \eta, 0 < u < 2n \} \]
\[ \subset \left\{ x \in \Omega : \frac{T_\delta(u^+)}{\delta} > \eta \right\} = \{ x \in \Omega : u^+ > \eta \delta \}. \]
Since \( \text{med}(u) = 0 \), we have
\[
\text{meas}\{x \in \Omega : u(x) > \eta \delta\} < \frac{\text{meas}(\Omega)}{2}.
\]
It follows that \( \forall \eta < \frac{1}{2} \),
\[
\text{meas}\{x \in \Omega : w_{n,k,\delta}(x) > \eta\} < \frac{\text{meas}(\Omega)}{2},
\]
which means \( \text{med}(w_{n,k,\delta}) \leq 0 \).

On the other hand since
\[
\forall \eta > 0, \{ x \in \Omega : w_{n,k,\delta}(x) > -\eta \} \supset \{ x \in \Omega : u \geq 0 \}
\]
and
\[
\text{meas}\{x \in \Omega : u \geq 0\} \geq \frac{\text{meas}(\Omega)}{2},
\]
we deduce that
\[
\text{meas}\{x \in \Omega : w_{n,k,\delta}(x) > -\eta\} \geq \frac{\text{meas}(\Omega)}{2}, \forall \eta > 0,
\]
which means \( \text{med}(w_{n,k,\delta}) \geq 0 \). We can conclude that
\[
\text{med}(w_{n,k,\delta}) = 0.
\]

Then from Poincaré-Wirtinger inequality, by using (4.21) and (4.26), we obtain
\[
\int_{\Omega} |w_{n,k,\delta}|^p dx \leq C \int_{\Omega} |\nabla w_{n,k,\delta}|^p dx
\]
\[
\leq C \left\{ \frac{1}{n^p} \int_{\Omega} |\nabla T_{2n}(u)|^p dx + \frac{1}{k^p} \int_{\Omega} h_n^p(u) |\nabla T_k(u - v)|^p dx
\right.
\]
\[
\left. + \frac{1}{\delta^p k^p} \int_{\Omega} h_n^p(u) |T_k(u - v)|^p \left| \nabla T_{\delta}(u^+) \right|^p \left| \nabla T_{\delta}(v^-) \right|^p dx \right\}.
\]

We now prove that
\[
\lim_{n \to +\infty} \frac{1}{n^p} \int_{\Omega} |\nabla T_{2n}(u)|^p dx = 0,
\]
\[
\lim_{k \to 0} \frac{1}{k^p} \int_{\Omega} h_n^p(u) |\nabla T_k(u - v)|^p dx = 0,
\]
\[
\lim_{\delta \to 0} \frac{1}{\delta^p k^p} \int_{\Omega} h_n^p(u) |T_k(u - v)|^p \left| \nabla T_{\delta}(u^+) \right|^p dx = 0,
\]
\[
\lim_{\delta \to 0} \frac{1}{\delta^p k^p} \int_{\Omega} h_n^p(u) |T_k(u - v)|^p \left| \nabla T_{\delta}(v^-) \right|^p dx = 0.
\]
Clearly (4.28) is a consequence of (2.13) in Definition 2.2. As far as (4.29) is concerned, by Hölder inequality we have

\[ \frac{1}{k^p} \int_{\Omega} h_n^p(u) |\nabla T_k(u - v)|^p \, dx \leq \left( \frac{1}{k^2} \int_{\{0 < |u-v| < k\}} \frac{|\nabla u - \nabla v|^2}{(|\nabla u| + |\nabla v|)^{2-p}} \, dx \right)^{\frac{p}{2}} \times \left( \int_{\{0 < |u-v| < k\}} h_n^{2p}(u)(|\nabla u| + |\nabla v|)^p \, dx \right)^{\frac{1}{2}} \]

and in view of the definition of \( h_n \), if \( n \) is fixed, for any \( k < 1 \) we have

\[ \int_{\{0 < |u-v| < k\}} h_n^{2p}(u)(|\nabla u| + |\nabla v|)^p \, dx \leq \int_{\Omega} (|\nabla T_{2n}(u)| + |\nabla T_{2n+1}(v)|)^p \, dx \leq C_n, \]

where \( C_n > 0 \) is a constant depending on \( n \) (and independent of \( k \)). From (4.6) it follows that for any fixed \( n > 0 \) (4.29) holds.

We now turn to (4.30) and (4.31). Observe that

\[ \frac{1}{k^p \delta^p} |T_k(u - v)|^p |\nabla T_\delta(u^+)|^p = \frac{1}{k^p \delta^p} |T_k(u - v)|^p |\nabla u|^p \chi_{\{0 < u < \delta\}} \]

a.e. in \( \Omega \). Since \( u > v \) a.e. in \( \Omega \) and \( \text{meas}\{x \in \Omega : u > 0, v < 0\} = 0 \), we get

\[ |T_k(u - v)|^p \chi_{\{0 < u < \delta\}} \leq \delta^p, \]

and then

\[ \frac{1}{k^p \delta^p} |T_k(u - v)|^p |\nabla T_\delta(u^+)|^p \leq \frac{1}{k^p} |\nabla u|^p \chi_{\{0 < u < \delta\}}. \]

The Lebesgue dominated Theorem gives for fixed \( k > 0 \),

\[ \frac{1}{k} |\nabla u| \chi_{\{0 < u < \delta\}} \rightarrow 0 \quad \text{strongly in } L^p(\Omega), \text{ as } \delta \rightarrow 0. \]

We deduce (4.30). In analogous way we get (4.31).

By collecting (4.30), (4.31), (4.29), (4.28) and (4.27) we can conclude that

\[ \lim_{n \rightarrow +\infty} \lim_{k \rightarrow 0^+, \delta \rightarrow 0} \int_{\Omega} |w_{n,k,\delta}|^p \, dx = 0, \]

which gives, via Lebesgue dominated Theorem,

\[ \left| \text{sign} (u - v) \left( \chi_{\{u > 0\}} - \chi_{\{v < 0\}} \right) \right| = 0. \]

This implies that \( \chi_{\{u > 0\}} = \chi_{\{v < 0\}} \) a.e. in \( \Omega \); this yields a contradiction since we have proved that \( u \) and \( v \) have the same sign.

The same arguments yield that we can not have \( u < v \) a.e. in \( \Omega \). The conclusion follows.
Proof of Theorem 4.2. Arguing as in the previous theorem we obtain (4.5) and we proceed by dividing the proof by steps. The main difference with respect to the proof of Theorem 4.1 is that for \( p > 2 \) we have to control quadratic terms in \( u - v \) (see (4.32)) while \( u \) and \( v \) are solutions to a \( p \)-growth problem.

Step 1. By passing to the limit in (4.5) first as \( n \to +\infty \), then as \( k \to 0 \) this step is devoted to prove that

\[
\lim_{k \to 0} \frac{1}{k^2} \int \Omega |\nabla T_k(u - v)|^2 \, dx = 0.
\]

We pass to the limit in (4.5) first as \( n \to +\infty \), then as \( k \to 0 \). Arguing as in Step 1 of the previous theorem we get that

\[
\lim_{n \to +\infty} \int \Omega \left( a(x, \nabla u) + \Phi(x, u) - a(x, \nabla v) - \Phi(x, v) \right) \cdot \nabla u \, dx = 0
\]

\[
\lim_{n \to +\infty} \int \Omega \left( a(x, \nabla u) + \Phi(x, u) - a(x, \nabla v) - \Phi(x, v) \right) \cdot \nabla v \, dx = 0.
\]

Then, using the assumptions on the strong monotonicity on the operator (2.4), the local Lipschitz condition on \( \Phi \) (2.7) with \( \tau \) which satisfies (3.3) and Young inequality we get

\[
\frac{\beta}{2} \int \Omega h_n(u)h_n(v)(1 + |\nabla u| + |\nabla v|)^{p-2}|\nabla T_k(u - v)|^2 \, dx \\
\leq \omega_k(n) + \frac{k^2}{2\beta} \int_{\{0 < |u - v| < k\}} h_n(u)h_n(v)|c(x)|^2(1 + |u| + |v|)^{2\tau} \, dx,
\]

where \( \lim_n \omega_k(n) = 0 \). We then obtain

\[
\frac{\beta}{2} \int \Omega h_n(u)h_n(v)|\nabla T_k(u - v)|^2 \, dx \leq \omega_k(n) \\
+ \frac{k^2}{2\beta} \int_{\{0 < |u - v| < k\}} h_n(u)h_n(v)|c(x)|^2(1 + |u| + |v|)^{2\tau} \, dx.
\]

(4.33)
By Hölder inequality and assumptions on the data we get

\begin{equation}
(4.34) \quad \int_{\Omega} h_n(u)h_n(v)|c(x)|^2(1 + |u| + |v|)^{2\tau} \, dx \\
\leq \left( \int_{\{x \in \Omega : |u| < 2n, |v| < 2n\}} h_n(u)h_n(v)|c(x)|^t \, dx \right)^{\frac{2}{t}} \\
\times \left( \int_{\{x \in \Omega : |u| < 2n, |v| < 2n\}} h_n(u)h_n(v)(1 + |u| + |v|)^{\nu} \, dx \right)^{\frac{2t}{t-2}}
\end{equation}

where \( \nu = \frac{2t\tau}{t-2} \). According to the assumption on \( \tau \) we have

\[ \frac{2t\tau}{t-2} < \frac{N(p-1)}{N-p} \]

which implies \( (1 + |u| + |v|)^\nu \in L^1(\Omega) \). Making use of Fatou Lemma and (4.34) we obtain

\begin{equation}
(4.35) \quad |c(x)|^2(1 + |u| + |v|)^{2\tau} \in L^1(\Omega).
\end{equation}

We can pass to the limit as \( n \to +\infty \) in (4.33), then using Fatou Lemma we get

\begin{equation}
(4.36) \quad \frac{1}{k^2} \int_{\Omega} |\nabla T_k(u - v)|^2 \, dx \\
\leq \frac{1}{\beta^2} \int_{\{0 < |u - v| < k\}} |c(x)|^2(1 + |u| + |v|)^{2\tau} \, dx.
\end{equation}

Recalling that \( \chi_{\{0 < |u - v| < k\}} \) converges to 0 a.e. as \( k \) goes to zero Lebesgue dominated Theorem and (4.35) allow one to conclude that (4.32) holds.

**Step 2.** We prove that either

\[ \begin{cases} 
    u = v & \text{a.e. in } \Omega, \\
    u < v & \text{a.e. in } \Omega, \\
    u > v & \text{a.e. in } \Omega.
\end{cases} \]

Let us consider the function \( h_n(u)\frac{T_k(u - v)}{k} \) and observe that for \( k < n \)

\[ h_n(u)\frac{T_k(u - v)}{k} = h_n(u)\frac{T_k(T_{3n}(u) - T_{3n}(v))}{k} \in L^\infty(\Omega) \cap W^{1,p}(\Omega). \]
Since $p \geq 2$ the function $h_n(u)\frac{T_k(u-v)}{k}$ belongs to $H^1(\Omega)$ by Poincaré-Wirtinger inequality we get

$$
\int_\Omega \left| h_n(u)\frac{T_k(u-v)}{k} - \text{med} \left( h_n(u)\frac{T_k(u-v)}{k} \right) \right|^2 dx 
\leq C \int_\Omega \left| \nabla \left( h_n(u)\frac{T_k(u-v)}{k} \right) \right|^2 dx.
$$

(4.37)

Let us evaluate the integral at the right-hand side. We show that it goes to zero first as $k \to 0$ then as $n \to +\infty$.

Since

$$
\nabla \left( h_n(u)\frac{T_k(u-v)}{k} \right) = h'_n(u)\nabla u \frac{T_k(u-v)}{k} + h_n(u) \frac{T_k(u-v)}{k}
$$
a.e. in $\Omega$

and $\left| \frac{T_k(u-v)}{k} \right| \leq 1$ we get

$$
\int_\Omega \left| \nabla \left( h_n(u)\frac{T_k(u-v)}{k} \right) \right|^2 dx
\leq \int_\Omega \left| h'_n(u)\nabla u \right|^2 dx + \frac{1}{k^2} \int_\Omega h_n(u)^2 \left| \nabla T_k(u-v) \right|^2 dx.
$$

(4.38)

It is easy to verify that for fixed $n$, as $k \to 0$

$$
\nabla \left( h_n(u)\frac{T_k(u-v)}{k} \right) \longrightarrow h'_n(u)\nabla u \text{sign}(u-v), \text{ in } (L^2(\Omega))^N
$$

Moreover by the definition of $h_n$

$$
\int_\Omega \left| h'_n(u)\nabla u \right|^2 dx \leq \frac{1}{n^2} \int_\Omega \left| \nabla T_{2n}(u) \right|^2 dx
$$

so that (2.13), (4.32) and (4.38) lead to

$$
\lim_{n \to +\infty} \lim_{k \to 0} \int_\Omega \left| \nabla \left( h_n(u)\frac{T_k(u-v)}{k} \right) \right|^2 dx = 0.
$$

Then, using (4.37), we deduce

$$
\lim_{n \to +\infty} \lim_{k \to 0} \int_\Omega \left| h_n(u)\frac{T_k(u-v)}{k} - \text{med} \left( h_n(u)\frac{T_k(u-v)}{k} \right) \right|^2 dx = 0.
$$

(4.39)
Since \( |h_n(u)\frac{T_k(u-v)}{k}| \leq 1 \), we obtain
\[
\left| \text{med} \left( h_n(u)\frac{T_k(u-v)}{k} \right) \right| \leq 1, \quad k > 0.
\]
It follows that, up to a subsequence, by (4.39)
\[
\lim_{n \to +\infty} \lim_{k \to 0} \text{med} \left( h_n(u)\frac{T_k(u-v)}{k} \right) = \gamma.
\]
for a suitable constant \( \gamma \in \mathbb{R}, |\gamma| \leq 1 \).
On the other hand since \( u \) is finite a.e.
\[
\lim_{k \to 0} h_n(u)\frac{T_k(u-v)}{k} = h_n(u)\text{sign}(u-v), \quad \text{a.e. and } L^\infty(\Omega) \text{ weak-*},
\]
\[
\lim_{n \to +\infty} h_n(u)\text{sign}(u-v) = \text{sign}(u-v), \quad \text{a.e. and } L^\infty(\Omega) \text{ weak-*}
\]
Then, up to subsequence, by (4.39) we get
\[
\int_{\Omega} |\text{sign} (u-v) - \gamma|^2 \, dx = 0
\]
This implies
\[
\gamma = 0 \quad \text{or} \quad \gamma = -1 \quad \text{or} \quad \gamma = 1.
\]
This means that either
\[
u = v, \text{ a.e. in } \Omega \text{ or } u < v, \text{ a.e. in } \Omega \text{ or } u > v, \text{ a.e. in } \Omega.
\]
Arguing as in Step 3 of the previous theorem, we can prove that the last two possibilities can not occur. Then conclusion follows.

\[\square\]

**Remark 4.3.** As in the case of weak solutions, the existence of renormalized solutions hold for a class of more general problems (3.25) where \( f \) belongs to \( L^1(\Omega) \), \( \Phi \) verifies growth conditions and \( a(x,r,\xi) \) is a Leray-Lions operator which depends on \( x \), \( s \) and \( \xi \) (see [8]).

Due to the lack of regularity of \( u \) in the \( L^1 \) case by using the techniques developed in the present paper it seems not possible to obtain uniqueness result when \( a \) verifies (3.26)-(3.29). Let us explain the main obstacle in the case \( p = 2 \) and what kind of stronger assumptions on \( a \) insures the uniqueness of the renormalized solution. In view of the proof of Theorem 4.1 and Theorem 4.2 the only new difficulty when \( a \) depends on \( x, r, \xi \) is to prove Step 1 which is when \( p = 2 \)
\[
(4.40) \quad \lim_{k \to 0} \frac{1}{k^2} \int_{\Omega} |\nabla T_k(u-v)|^2 \, dx = 0.
\]
In Step 2 and Step 3 the structure of the operator does not play any role. Equation (4.5) in which we pass to the limit first as \( n \to +\infty \) and then as \( k \to 0 \) to derive (4.40) becomes

\[
\int_\Omega h_n(u)h_n(v)(a(x, u, \nabla u) - a(x, v, \nabla v)) \cdot \nabla T_k(u - v) \, dx \\
+ \int_\Omega \left( h_n(u)h_n(v)(\Phi(x, u) - \Phi(x, v)) \cdot \nabla T_k(u - v) \right) \, dx \\
+ \int_\Omega h_n'(u)h_n(v)T_k(u - v)(a(x, u, \nabla u) \\
\quad + \Phi(x, u) - a(x, v, \nabla v) - \Phi(x, v)) \cdot \nabla u \, dx \\
+ \int_\Omega h_n(u)h_n'(v)T_k(u - v)(a(x, u, \nabla u) \\
\quad + \Phi(x, u) - a(x, v, \nabla v) - \Phi(x, v)) \cdot \nabla v \, dx = 0.
\]

Since the operator is pseudo-monotone the main obstacle is the control of the first term of (4.41).

\[
\int_\Omega h_n(u)h_n(v)(a(x, u, \nabla u) - a(x, v, \nabla v)) \cdot \nabla T_k(u - v) \, dx \\
= \int_\Omega h_n(u)h_n(v)(a(x, u, \nabla u) - a(x, v, \nabla v)) \cdot \nabla T_k(u - v) \, dx \\
+ \int_\Omega h_n(u)h_n(v)(a(x, u, \nabla v) - a(x, v, \nabla v)) \cdot \nabla T_k(u - v) \, dx \\
\geq \beta \int_\Omega h_n(u)h_n(v)|\nabla T_k(u - v)|^2 \, dx \\
+ \int_\Omega h_n(u)h_n(v)(a(x, u, \nabla v) - a(x, v, \nabla v)) \cdot \nabla T_k(u - v) \, dx \\
\geq \frac{\beta}{2} \int_\Omega h_n(u)h_n(v)|\nabla T_k(u - v)|^2 \, dx \\
- \int_{\{|u-v|<k\}} h_n(u)h_n(v)|a(x, u, \nabla v) - a(x, v, \nabla v)|^2 \, dx.
\]

Passing first as \( n \to +\infty \) and then as \( k \to 0 \) requires to have \( \chi_{\{0<|u-v|<k\}} |a(x, u, \nabla v) - a(x, v, \nabla v)|^2 \in L^1(\Omega) \). If \( a \) verifies

\[
|a(x, s, \xi) - a(x, r, \xi)| \leq |s - r||\xi|,
\]

then

\[
\chi_{\{0<|u-v|<k\}} |a(x, u, \nabla v) - a(x, v, \nabla v)|^2 \leq k^2|\nabla v|^2
\]

and we cannot expect to have \( |\nabla v|^2 \in L^1(\Omega) \) for \( L^1 \) data. However by assuming a stronger control of the Lipschitz coefficient of \( a(x, r, \xi) \)
with respect to $r$, namely
\[ |a(x, s, \xi) - a(x, r, \xi)| \leq \frac{|s - r|}{(1 + |s| + |r|)^\lambda} |\xi|, \]
with $\lambda > \frac{1}{2}$, we have
\[ \chi_{\{0 < |u - v| < k\}} |a(x, u, \nabla v) - a(x, v, \nabla v)|^2 \leq k^2 \frac{|
abla v|^2}{(1 + |v|)^{2\lambda}} \]
and since $2\lambda > 1$, estimate (2.16) implies that
\[ \chi_{\{0 < |u - v| < k\}} |a(x, u, \nabla u) - a(x, v, \nabla v)|^2 \in L^1(\Omega). \]
It follows that
\[ \chi_{\{0 < |u - v| < k\}} \frac{1}{k^2} |a(x, u, \nabla v) - a(x, v, \nabla v)|^2 \rightarrow 0, \text{ in } L^1(\Omega). \]
Since the other terms in (4.41) can be controlled by similar methods to the one used in Theorem 4.2 we are able to conclude that (4.40) holds and then that $u = v$ a.e. in $\Omega$.

We now give the complete version of Theorem 4.1 and 4.2 for problem (3.25). As in the weak case we assume that $a(x, r, \xi)$ is a Carathéodory function which verifies (3.26), (3.27), (3.28), $f \in L^1(\Omega)$ and $\Phi$ verifies (2.5) and (2.7).

When $1 < p < 2$ if $\tau \leq p - \frac{3}{2}$ and if $a(x, r, \xi)$ satisfies
(4.42)
\[ |a(x, s, \xi) - a(x, r, \xi)| \leq C \frac{|s - r|}{(1 + |s| + |r|)^\lambda} \left( |\xi|^{p-1} + |s|^{p-1} + |r|^{p-1} + h(x) \right), \]
with $\lambda > \frac{1}{2}$, $h \geq 0$ and $h \in L^{p'}(\Omega)$, then the renormalized solution $u$ with null median of (3.25) is unique.

When $p \geq 2$ if
\[ \tau \leq \frac{N(p-1)}{N-p} \left( \frac{1}{2} - \frac{1}{t} \right) \]
and if $a(x, r, \xi)$ satisfies
(4.43)
\[ |a(x, s, \xi) - a(x, r, \xi)| \leq C \frac{|s - r|}{(1 + |s| + |r|)^\lambda} \left( |\xi|^{p-1} + |s|^{\frac{(N-1)(p-1)}{N(p-1)}} + |r|^{\frac{(N-1)(p-1)}{N(p-1)}} + h(x) \right), \]
with $\lambda > \frac{1}{2}$, $h \geq 0$ and $h \in L^2(\Omega)$, then the renormalized solution $u$ with null median of (3.25) is unique. It is worth noting that (4.42) and (4.43) are similar except in the power of $|s|$ and $|r|$ and the regularity of $h$. The main reason is that for $p \geq 2$ we use quadratic method for a $p$-growth equation.
