The synthesis of C-glycosides has become an area of intense study over the last three decades.\textsuperscript{1} Replacement of the anomeric oxygen atom with a methylene group allows C-glycosides to have higher chemical and enzymatic stability. There are few routes to benzyl C-glycosides reported in the literature. The most common involve hydroboration of olefinated carbohydrate derivatives and Suzuki coupling with aryl bromides,\textsuperscript{2} additions of benzyllithium to gluconolactones and reduction,\textsuperscript{3} additions of benzylzinc reagents to glycals,\textsuperscript{4} additions of benzylmagnesium reagents to glucosyl halides,\textsuperscript{5} ring-closing metathesis to form an \textit{endo}-glycal followed by hydroboration,\textsuperscript{6} iodocyclization,\textsuperscript{7} and Ramberg-Bäcklund rearrangement followed by hydrogenation of the resulting \textit{exo}-glycal.\textsuperscript{8}

We report herein two new methods for the synthesis of C-glycosides where the aryl partner can be easily accessed from a phenol. The first route is based on an unprecedented intramolecular oxa-Michael cyclisation to an electron-deficient styryl derivative \textsuperscript{2} to form the protected C-glycosides \textsuperscript{1} directly (Scheme 1). Only two examples of related intramolecular oxa-Michael reactions are described in the literature.\textsuperscript{9} The substrates required for the cyclisation reaction can be prepared by cross-metathesis (CM) between electron-poor styrenes and the known olefin \textsuperscript{3,10} easily obtained by Wittig reaction between commercially available 2,3,4,6-tetra-O-benzyl-D-glucopyranose and methylenetriphenylphosphorane (93% yield).

Olefin \textsuperscript{3} was first submitted to cross-metathesis\textsuperscript{11} with \textit{p}-nitrostyrene,\textsuperscript{12} using Grubbs second-generation catalyst\textsuperscript{13} (Table 1). The yields were low because of incomplete conversion of olefin \textsuperscript{3}, 67% of which was recovered with 10 mol\% of the catalyst (entry 1), and 38% with 15 mol\% of the catalyst (entry 2). The best yield for the reaction (62%) was obtained with the Hoveyda-Grubbs second-generation catalyst (HG2) in refluxing toluene (entry 3).\textsuperscript{14} Only the \textit{E}-isomer of \textsuperscript{2a} was formed. Performing the reaction under microwave conditions did not improve the yield.\textsuperscript{15} The reaction was plagued by isomerisation of the alkene in \textsuperscript{3}, and the \textit{A}\textsuperscript{2,3} \textit{E}-isomer of \textsuperscript{3} was formed in up to 24% yield.

Various styrenes (EWG = SO₂Ph, CHO, COMe, COOMe) were then submitted to CM with olefin 3 under the previously optimised conditions, and the yields ranged between 50% and 62% (E isomer only) (Table 2). In all cases, the Δ²⁻¹ isomer was formed, but it was easily separated from the desired metathesis products.

We then decided to test the Michael cyclisation on substrate 2a, which possesses the strongest electron-withdrawing group (EWG = NO₂, Table 3). When this olefin was treated with strong bases such as t-BuOK® or KHMDS, no cyclisation occurred. Instead, we observed elimination of a benzyloxy group, even at -78 °C, to furnish the conjugated diene 4a. With a weaker base such as triethylamine, no reaction occurred after 12 hours and with sodium hydride, the starting material was recovered at 20 °C and only degradation products were obtained at 50 °C. With DBU at ambient temperature and low concentration, the starting material was recovered (entry 6). The use of 3 equiv of DBU at 0.05 M led to 1a in 66% yield after 12 hours (entry 7). Selectivity was in favor of the α-isomer (α/β = 75:25). The two diastereomers could be separated by column chromatography, yielding 50% of the α-isomer and 16% of the β-isomer. Finally, optimum conditions required a substoichiometric amount of DBU (0.8 equiv) at higher concentration (0.2 M), and compound 1a was obtained in 78% yield after 24 hours (entry 8). Another weak base K₂CO₃ also furnished C-glycoside 1a in good yield withouts the same diastereomeric ratio (entry 9). The stereochimetry of the minor diastereomer was determined by examining the coupling constants of the proton at the newly formed stereogenic center (J₂,₃ = 9.2 Hz, trans relationship). Submitting a mixture of diastereomers of 1a enriched in the β-isomer (α/β = 25:75) to 2 equiv of DBU for 24 hours (0.2 M concentration) did not change the isomer ratio, implying that the conjugate addition was under kinetic control.

* α/β = 75:25

Various substrates (EWG = SO₂Ph, CHO, COMe, COOMe) were submitted to the optimised oxa-Michael cyclisation conditions (Table 4). A similar result was found with EWG = SO₂Ph (74% yield, α/β = 70:30, entry 2). With weaker electron-withdrawing groups such as CHO, COMe, or COOMe, no reaction occurred, even in refluxing dichloromethane (entries 3-5). Lewis acids were added to the reaction with the ester substrate 2e to some effect, but the yield never exceeded 20% (entry 6). This conjugate addition seems to be limited to substrates with strong electron-withdrawing substituents such as a nitro or a sulfonyl group, but a large range of functional groups on the phenyl ring should be easily accessible from the nitro group.

Table 4. Oxa-Michael cyclisations of 2a-e

![Chemical structure](image)
Another approach was then envisaged, that could produce benzyl C-glycosides with no electron-withdrawing substituents on the phenyl ring (Scheme 2). These glycosides would be formed by cyclisation of hydroxy alkenes 6, followed by reduction of the resulting alkenes 5. Alkenes 6 would be prepared by Sonogashira coupling of terminal alkyne 7 with the required aryl triflates.

Scheme 2. Retrosynthetic approach involving alkyne substrates

The formation of alkyne 7 proved to be more difficult than expected. Corey-Fuchs\textsuperscript{18} or Bestmann-Ohira\textsuperscript{19} reactions did not convert the lactol at ambient temperature, or gave degradation products in refluxing THF. Fortunately, Wittig reaction with (chloromethyl)triphenylphosphonium iodide afforded the corresponding chloro-alkene in 80% yield as a 55:45 E/Z mixture (Scheme 3),\textsuperscript{20} and subsequent elimination of HCl led to alkyne 7. Sonogashira coupling between 7 and iodobenzene furnished alkyne 6f in 87% yield.

We investigated the cyclisation under different conditions: acidic (PPTS), basic (MeONa, KH) or with PdCl\textsubscript{2}(CN)\textsubscript{2}, unsuccessfully. We then considered gold catalysis, which has proved to be efficient for several heterocyclisation reactions.\textsuperscript{22} Contrary to what was observed by Palc and co-workers for similar substrates,\textsuperscript{23} the reaction proceeded smoothly under Au(III) catalysis to furnish compound 5f\textsuperscript{ob} in 82% yield as the Z-isomer, exclusively (Scheme 4).\textsuperscript{24} When the gold catalyst was not filtered from the reaction mixture before evaporation of the solvent, hemiketal 8f was obtained as the major product.\textsuperscript{25} Olefin 5f was then hydrogenated following the procedure reported by Belica and Franck\textsuperscript{26} to furnish benzyl C-glycoside 1f in 89% yield. Reduction of hemiketal 8f with Et\textsubscript{3}SiH/BF\textsubscript{3}•OEt\textsubscript{2} was also efficient, giving 1f in 90% yield.\textsuperscript{26}

Scheme 3. Preparation of alkyne 7 and Sonogashira coupling

We investigated the cyclisation under different conditions: acidic (PPTS), basic (MeONa, KH) or with PdCl\textsubscript{2}(CN)\textsubscript{2}, unsuccessfully. We then considered gold catalysis, which has proved to be efficient for several heterocyclisation reactions.\textsuperscript{22} Contrary to what was observed by Palc and co-workers for similar substrates,\textsuperscript{23} the reaction proceeded smoothly under Au(III) catalysis to furnish compound 5f\textsuperscript{ob} in 82% yield as the Z-isomer, exclusively (Scheme 4).\textsuperscript{24} When the gold catalyst was not filtered from the reaction mixture before evaporation of the solvent, hemiketal 8f was obtained as the major product.\textsuperscript{25} Olefin 5f was then hydrogenated following the procedure reported by Belica and Franck\textsuperscript{26} to furnish benzyl C-glycoside 1f in 89% yield. Reduction of hemiketal 8f with Et\textsubscript{3}SiH/BF\textsubscript{3}•OEt\textsubscript{2} was also efficient, giving 1f in 90% yield.\textsuperscript{26}

Scheme 4. Cyclisations/reductions of 6f

In conclusion, we have developed two short syntheses of benzyl C-glycosides featuring an unprecedented oxa-Michael cyclisation and an efficient gold-catalysed ring-closure. The second approach also constitutes a new synthesis of benzyl exoglycals, which could be a good alternative to the Ramberg-Bäcklund rearrangement.\textsuperscript{8a,b} Depending on the route, we can obtain either α- or β-C-glycosides. The preparation of more complex benzyl C-glycosides is underway.

17. Procedure for the oxo-Michael addition: To a solution of 1,3,4,5-tetra-o- benzyl-7-(4-nitrophenyl)-hept-6-en-2-ol (80 mg, 0.12 mmol) in CHCl3 (0.4 mL) was added 10 μL of DBU (0.06 mmol, 0.5 equiv). The solution was stirred for 24 h under a nitrogen atmosphere. The solution was concentrated under vacuum and was chromatographed (SiO2, 30% EtOAc/petroleum ether) to furnish the desired product as a yellow oil (63 mg, 78%).

21. Elimination only occurred from the E-olefin, which explains the modest overall yield (45%) for 2 steps.

24. We did not perform the reaction with AuCl.

25. General procedures for gold-catalysed cyclisations: A sample of AuCl•5 (molecular weight of 60 mg, 0.16 mmol) was added to a solution of the alkene in THF (2 mL) under argon. The mixture was stirred at ambient temperature for 2 h. Work-up A: the solution was filtered on silica gel and concentrated under vacuum to furnish the desired compound. Work-up B: the solution was concentrated under vacuum then filtered on silica gel (30% EtOAc/petroleum ether) to furnish the desired compound. The general procedure with work-up A was used for the conversion of alkenes 6f (100 mg, 0.16 mmol) to afford compound 5f as a yellow oil (82 mg, 82%).

(continued)
