HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Abstract

The Tree Containment problem has many important applications in the study of evolutionary history. Given a phylogenetic network $N$ and a phylogenetic tree $T$ whose leaves are labeled by a set of taxa, it asks if $N$ and $T$ are consistent. While the case of binary $N$ and $T$ has received considerable attention, the more practically relevant variant dealing with biological uncertainty has not. Such uncertainty manifests itself as high-degree vertices (“polytomies”) that are “jokers” in the sense that they are compatible with any binary resolution of their children. Contrasting the binary case, we show that this problem, called Soft Tree Containment, is \text{NP}-hard, even if $N$ is a binary, multi-labeled tree in which each taxon occurs at most thrice. On the other hand, we reduce the case that each label occurs at most twice to solving a 2-SAT instance of size $O(|T|^3)$.

1 Introduction

With the dawn of molecular biology also came the realization that evolutionary trees, which have been widely adopted by biologists, are insufficient to describe certain processes that have been observed in nature. In the last decade, the idea of reticulate evolution, supporting events such as hybridization (occurring frequently in plants) and horizontal gene transfer (a dominating factor in bacterial evolution) [2, 14]. Reticulate evolution is described using “phylogenetic networks” (see the monographs by Gusfield [10] and Huson et al. [12]). A central question when dealing with both phylogenetic trees and networks is whether or not they represent consistent information, formulated as the question whether or not the network “displays” the tree. This problem is known as Tree Containment and it has been shown \text{NP}-hard [13, 16]. Due to its importance in the analysis of evolutionary history, attempts have been made to identify polynomial-time computable special cases [1, 5, 6, 8, 9, 13, 16, 17], as well as moderately exponential-time algorithms [7, 17]. However, all of these works are limited to binary networks and trees.

In reality, we cannot hope for perfectly precise evolutionary histories. In particular, speciation events (a species splitting off another) occurring in rapid succession (only a few thousand years between speciations) can often not be reliably placed in the correct order they occurred. The fact that the correct order of bifurcations is unknown is usually modeled by multifurcating vertices and, to tell them apart from speciation events resulting in multiple species, the former are called “soft polytomies” and the latter are called “hard polytomies”. Soft polytomies have a noteworthy impact on the question of whether a tree is compatible with a network: since a soft polytomy (also called “fan”) on the taxa $a$, $b$, and $c$ represents lack of knowledge regarding their history, we would consider any binary tree on the taxa $a$, $b$, and $c$ compatible with it. In this work, we present first algorithmic results for Tree Containment with soft polytomies (with we call Soft Tree Containment). We show that it is \text{NP}-hard, even if the network is “reticulation-visible” and all reticulation vertices have at most three parents, but if we lower this bound to two, the problem becomes solvable in cubic time.
Preliminaries. A phylogenetic network (or network for short) on a set $X$ of taxa is a rooted, leaf-labeled DAG in which all vertices that do not have in-degree at most one have out-degree exactly one. The former vertices are called tree vertices and the latter are called reticulations. A network without reticulations is called a (phylogenetic) tree. By default, no label occurs twice in a network, and we will make exceptions explicit by calling networks in which a label may occur more than once multi-labeled (note that networks are a special case of multi-labeled networks in which each label occurs only once). This allows us to use leaves and labels (taxa) interchangeably. For brevity, we abbreviate $\{x, y\}$ to $xy$, and $\{x, y, z\}$ to $xyz$. Let $N$ be a network with root $\rho_N$. We define a relation “$\preceq_N$” on subsets of $V(N)$ such that $U \preceq_N W$ if and only if $N$ contains a $u$-$w$-path for each $u \in U$ and $w \in W$. If $u \preceq_N w$, we call $u$ an ancestor of $v$ and $v$ a descendant of $u$. For each $v \in V(N)$, we let $N_v$ be the subnetwork of $N$ induced by $\{u \mid u \preceq_N v\}$ and we denote the set of leaf-labels in $N_v$ by $\mathcal{L}(v)$ and abbreviate $\mathcal{L}(N) := \mathcal{L}(\rho_N)$. Such a set is also called a cluster of $N$. Note that, if $N$ is a tree, $N_v$ is the subtree rooted at $v$. We abbreviate $n := |\mathcal{L}(\rho_N)|$. For any $X \subseteq V(N)$, we let $\text{LCA}_N(X)$ be the set of least common ancestors of $X$, that is, the minima (wrt. $\preceq_N$) among all vertices $u$ of $N$ with $X \preceq_N u$ (in particular, if $N$ is a tree, $\text{LCA}_N(X)$ is a single vertex, not a set). If clear from context, we may drop the subscript. Note that, in trees, the LCA of any three vertices has a unique minimum. For any $U \subseteq V(N)$, we denote the result of removing all vertices $v$ that do not have a descendant in $U$ by $N\mid_{|U}$ and $N\mid_{|L}$ is the result of supressing all degree-two vertices in $N\mid_{|L}$. Note that, if $N$ is a tree, then $N\mid_{|L}$ is the smallest subtree of $N$ containing the vertices in $L$ and the root of $N$ and $N\mid_{|L}$ is the smallest topological minor of $N$ containing the vertices in $L$ and the root of $N$. A vertex $u$ in $N$ is called stable on $v$ if all $\rho_N$-$v$-paths contain $u$. If, for each reticulation $u$ in $N$ there is some leaf $\ell$ such that $u$ is stable on $\ell$, then $N$ is called reticulation visible. Suppressing a vertex $u$ in $N$ with unique parent $p$ and unique child $c$ refers to the act of removing $u$ and adding the edge $pc$, unless this edge already exists.

A network is binary if all vertices except the root have degree ($=$in-degree + out-degree) at most three and the root has degree two. A binary network $N_B$ on three leaves $a$, $b$, and $c$ is called a triplet and we denote it by $abc$ if $c$ is a child of the root of $N_B$. $N_B$ is called binary resolution of a network $N$ if $N$ is a contraction of $N_B$. In this case, there is a surjective function $\chi : V(N_B) \to V(N)$ such that, contracting all edges $uv$ of $N_B$ with $\chi(u) = \chi(v)$ results in $N$ (more formally, for each $x, y \in V(N)$, the edge $xy$ exists in $N$ if and only if there is an edge between $\chi^{-1}(x)$ and $\chi^{-1}(y)$ in $N_B$). We call such a function contraction function of $N_B$ for $N$. We suppose that all binary resolutions are minimal, that is, they do not contain biconnected components with exactly one incoming and one outgoing edge. Observe that, when contracting edges of $N_B$ to form $N$, we never create vertices with in-degree and out-degree more than one.

**Observation 1.** Let $N_B$ be a binary resolution of a network $N$, let $\chi$ be a contraction function of $N_B$ for $N$, and let $u \in V(N)$. Then, $\chi^{-1}(u)$ does not contain a reticulation and a tree vertex with out-degree more than one.

If $N$ contains a subgraph $S$ that is isomorphic to a tree $T$, then we simply say that $N$ contains a subdivision of $T$. Slightly abusing notation, we consider each vertex $v \in V(T)$ equal to the vertex of $S$ (and, thus, of $N$) that $v$ is mapped to by an isomorphism. Thus, $S$ consists of $V(T)$ and some vertices of in- and out-degree one. The following definition is central to this work.

**Definition 1.** Let $N$ be a network and let $T$ be a tree. Then,
- $N$ firmly displays $T$ if and only if $N$ contains a subdivision of $T$ and
- $N$ softly displays $T$ if and only if there are binary resolutions $N_B$ of $N$ and $T_B$ of $T$ such that $N_B$ firmly displays $T_B$.

Definition 1 is motivated by the concept of “hard” and “soft” polytomies (that is, high degree vertices): In phylogenetics, a polytomy is called firm or hard if it corresponds to a split of multiple species at the same time and soft if it represents a set of binary speciations whose order cannot be determined from the available data. In this sense, a polytomy is compatible with another if and only if there is a biological “truth”, that is, a binary resolution, that is common to both. Note that, for binary $N$ and

\footnote{In this work, “isomorphic” always refers to isomorphism respecting leaf-labels, that is, all isomorphisms must map a leaf of label $\lambda$ to a leaf of label $\lambda$.}
such that $p$ children are not isomorphic. By Observation 5, there are vertices in each of them, a vertex $y \in L_2$.

**Proof.**

Throughout this work we will mostly use the soft variant and we will refer to it simply as “display” for the sake of readability. Note that a binary tree displays another binary tree if and only if they are isomorphic. Thus, in the special case that $N$ is a tree, the “display” relation is symmetrical, leading to the following observation.

**Observation 3.** A tree $T$ displays a tree $T'$ if and only if $T'$ displays $T$.

Finally, the central problem considered in this work is the following.

**Soft Tree Containment**

**Input:** A network $N$ and a tree $T$

**Question:** Does $N$ softly display $T$?

## 2 Display with Soft Polytomies

The concept of “display” is well-researched for binary trees, in particular, triplets.

**Observation 4** ([4]). Let $T_B$ be a binary tree and let $a, b, c \in L(T_B)$. Then, $T_B$ displays $ab|c$ if and only if $LCA(ab) < LCA(bc) = LCA(ac)$. Indeed, $T_B$ is uniquely identified by the set $D$ of displayed triplets, that is, $T_B$ is the only binary tree displaying the triplets in $D$.

However, the “display”-relation with soft polytomies lacks a solid mathematical base in the literature. In this section, we develop alternative characterizations of the term “(softly) display”. To do this, we use the following handy characterization of isomorphism for binary trees.

**Observation 5.** Binary trees $T_B$ and $T_B'$ on the same leaf-label set are isomorphic if and only if, for each $u \in V(T_B)$ and each $Y \subseteq L(u)$, $u$ has a child $v$ with $L(v) = Y$ if and only if $LCA_{T_B'}(L(u))$ has a child $v'$ with $L(v') = Y$.

**Lemma 1.** Let $N$ and $T$ be trees. Then, $N$ displays $T$ if and only if, for all $u \in V(T)$ and $v \in V(N)$, it holds that $L(u) \subseteq L(v)$, $L(u) \supseteq L(v)$ or $L(u) \cap L(v) = \emptyset$.

**Proof.** Observe that, since each label appears only once in $N$ and $T$, it holds that $N$ displays $T$ if and only if there are binary resolutions $N^B$ of $N$ and $T^B$ of $T$ such that $N^B$ and $T^B$ are isomorphic.

$\Rightarrow$: Let $N$ softly display $T$. Towards a contradiction, assume that there are $u \in V(N)$ and $u \in V(T)$ such that $L(u) \not\subseteq L(v)$, $L(u) \not\supseteq L(v)$ and $L(u) \cap L(v) \neq \emptyset$, that is, there are $x \in L(u) \setminus L(v)$, $y \in L(u) \cap L(v)$, and $z \in L(v) \setminus L(u)$. Since there are binary resolutions $N^B$ and $T^B$ of $N$ and $T$, respectively, such that $N^B$ and $T^B$ are isomorphic, there is a vertex $v'$ in $N^B$ with $L(v') = L(u)$ and a vertex $v''$ in $T$ with $L(v'' = L(v)$. Since $N^B$ and $T^B$ are trees and each leaf-label only appears once in each of them, $N^B$ contains the leaves $x$ and $y$ but not the leaf $z$. Analogously, $T^B$ contains the leaves $y$ and $z$ but not the leaf $x$, contradicting $N^B$ being isomorphic to $T^B$.

$\Leftarrow$: In order to show the contraposition, suppose that $N$ does not softly display $T$. Since $N$ does not softly display $T$, for any binary resolutions $N^B$ of $N$ and $T^B$ of $T$, it holds that $N^B$ and $T^B$ are not isomorphic. By Observation 5, there are vertices $p \in V(N^B)$ and $q := LCA_{T^B}(L(p))$ with children $p_1, p_2$ and $q_1, q_2$ of $q$, respectively, such that $L(p_1) \neq L(q_1)$ and $L(p_1) \neq L(q_2)$. We will use the fact that $L(p_1) \cup L(p_2) = L(p) = L(q) = L(q_1) \cup L(q_2)$.

**Case 1:** $L(p_i) \not\subseteq L(q_j)$ for any $i, j$. Then, there are taxa $x \in L(p_i) \cap L(q_j) = L(q_j) \setminus L(p_{3-i})$ $y \in L(q_j) \setminus L(p_i) = L(q_j) \setminus L(p_{3-i})$, and $z \in L(q_{3-j}) = L(q_{3-j}) \setminus L(p_i) = L(p_{3-i}) \setminus L(q_j)$.

The case where $L(q_j) \not\subseteq L(p_i)$ holds is analogous.

**Case 2:** None of $L(p_1), L(p_2), L(q_1)$, and $L(q_2)$ is subset of another. Then, there are taxa $x, y, z$ such that $x \in L(p_1) \cap L(q_1)$, $y \in L(q_1) \setminus L(p_1)$, and $z \in L(q_1) \setminus L(p_1)$.

$\blacksquare$
We can relate the two forms of “display” for triplets in non-binary trees.

**Observation 6.** Let $T$ be a tree and let $a, b, c \in \mathcal{L}(T)$. Then,
(a) $T$ firmly displays $ab|c$ if and only if $\text{LCA}(ab) <_T \{\text{LCA}(ac), \text{LCA}(bc)\}$.
(b) $T$ firmly displays $ac|b$ or $bc|a$ if and only if $T$ does not softly display $ab|c$.

**Lemma 2.** A tree $T$ on $X$ softly displays a tree $T'$ on $X$ if and only if for all $a, b, c \in X$,

- $T$ firmly displays $ab|c$ if and only if $T'$ softly displays $ab|c$, and
- $T'$ firmly displays $ac|b$ or $bc|a$ if and only if $T$ softly displays $ab|c$.

**Proof.** “$\Rightarrow$”: By Observation 3, it suffices to show the first of the claimed implications, so let $\text{LCA}_{T'}(ab) <_T \text{LCA}_T(ab)$ and assume towards a contradiction that $T'$ does not display $ab|c$. By Observation 6, we can suppose without loss of generality that $T'$ firmly displays $ac|b$. But then, for $u := \text{LCA}_T(ab)$ and $v := \text{LCA}_{T'}(ac)$, we have $a \in \mathcal{L}(u) \cap \mathcal{L}(v)$, $b \in \mathcal{L}(u) \setminus \mathcal{L}(v)$, and $c \in \mathcal{L}(v) \setminus \mathcal{L}(u)$. Thus, by Lemma 1, $T$ does not display $T'$.

“$\Leftarrow$”: Towards a contradiction, assume that $T$ does not display $T'$. By Lemma 1, there are $u \in \mathcal{V}(T)$ and $v \in \mathcal{V}(T')$ and $a, b, c \in X$ such that $a \in \mathcal{L}(u) \cap \mathcal{L}(v)$, $b \in \mathcal{L}(u) \setminus \mathcal{L}(v)$, and $c \in \mathcal{L}(v) \setminus \mathcal{L}(u)$. Thus, $\text{LCA}_T(ab) <_T \text{LCA}_{T'}(ab)$ and $\text{LCA}_{T'}(ac) <_T \text{LCA}_T(ac)$. By Observation 6, $T$ firmly displays $ab|c$ and $T'$ firmly displays $ac|b$. Applying the implications of the lemma, we get that $T'$ softly displays $ab|c$ and $T$ softly displays $ac|b$, thereby contradicting Observation 6.

The final ingredient to our alternative characterization is the observation that, in (multi-labeled) trees, edge contraction does not change the ancestor relation.

**Observation 7.** Let $T$ be a tree, let $T'$ be the result of contracting a vertex $u$ onto its parent $v$, and let $Y$ and $Z$ be sets of leaves common to $T$ and $T'$. Then,
(a) $\text{LCA}_T(Y) \leq_T \text{LCA}_T(Z) \iff \text{LCA}_{T'}(Y) \leq_{T'} \text{LCA}_{T'}(Z)$ and
(b) $\text{LCA}_T(Y) <_T \text{LCA}_T(Z) \iff \text{LCA}_{T'}(Y) <_{T'} \text{LCA}_{T'}(Z)$.

We can now prove the following alternative definition of “display”.

**Lemma 3.** Let $T$ be a tree on the label-set $X$.
(a) $T$ displays the leaf-triplet $ab|c$ if and only if $\text{LCA}(ab) \leq \{\text{LCA}(bc), \text{LCA}(ac)\}$.
(b) $T$ displays a binary tree $T_B$ on $X$ if and only if $T$ displays all triplets displayed by $T_B$.
(c) $T$ displays a tree $T'$ on $X$ (and vice versa) if and only if there is a binary tree $T_B$ on $X$ displayed by both $T$ and $T'$.
(d) A network $N$ displays $T$ if and only if $N$ contains (as subgraph) a tree $T'$ on $X$ that displays $T$.

**Proof.** (a). By definition, $T$ displays $ab|c$ if and only if there is a binary resolution $T_B$ of $T$ displaying $ab|c$. By Observation 4, $T_B$ displays $ab|c$ if and only if $\text{LCA}_{T_B}(ab) \leq \{\text{LCA}_{T_B}(bc), \text{LCA}_{T_B}(ac)\} = \text{LCA}_{T_B}(bc)$. Now, since $T_B$ is binary, we cannot have $\text{LCA}_{T_B}(ab) = \text{LCA}_{T_B}(bc)$ and, thus, $\text{LCA}_{T_B}(ab) \leq \{\text{LCA}_{T_B}(ac), \text{LCA}_{T_B}(bc)\}$ which, by Observation 7, is equivalent to $\text{LCA}(ab) \leq_T \{\text{LCA}(ac), \text{LCA}(bc)\}$.

(b). “$\Rightarrow$”: Assume towards a contradiction that a triplet $ab|c$ of $T_B$ is not displayed by $T$ and recall that $\{\text{LCA}(ab), \text{LCA}(ac), \text{LCA}(bc)\}$ has a unique minimum $x$. Since, by (a), $\text{LCA}(ab) \not\leq_T \text{LCA}(bc)$, we have $x <_T \text{LCA}(ab) \leq_T \text{LCA}(bc)$. Without loss of generality, let $x = \text{LCA}(ac)$. Then, by Observation 7, $\text{LCA}_{T_B}(ac) \leq_{T_B} \text{LCA}_{T_B}(bc)$, implying that $T_B$ displays $ac|b$. Hence, $T_B$ displays conflicting triples, contradicting Observation 4.

“$\Leftarrow$”: Assume towards a contradiction that $T$ does not display $T_B$. By Lemma 1, there are vertices $u \in \mathcal{V}(T)$ and $v_B \in \mathcal{V}(T_B)$ such that $\mathcal{L}(u)$ and $\mathcal{L}(v_B)$ intersect, but are not in the subset relation, that is, there are $x \in \mathcal{L}(u) \cap \mathcal{L}(v_B)$, $y \in \mathcal{L}(v_B) \setminus \mathcal{L}(u)$ and $z \in \mathcal{L}(u) \cap \mathcal{L}(v_B)$. Thus, $x, z <_T \text{LCA}(xyz)$ and $y, z <_T \text{LCA}_{T_B}(yz) \leq_T u <_T \text{LCA}_{T_B}(y)$. Then, $u <_T \text{LCA}_{T_B}(x)$ and $y, z <_T \text{LCA}_{T_B}(yz) \leq_T v_B <_T \text{LCA}_{T_B}(yz)$.

(c). By definition, $T$ displays $T'$ if and only if there are binary resolutions $T_B$ and $T_B'$ of $T$ and $T_B$, respectively, such that $T_B$ displays $T'_B$. Note that, if such trees exist then they are equal since,
by (b), $T_B$ displays all triplets displayed by $T_B^*$ and, by Observation 4, $T_B = T_B^*$. Conversely, by Observation 2, all binary trees on $X$ displayed by $T$ and $T'$ are binary resolutions of $T$ and $T'$.

(d). $\Rightarrow$: By definition, there are binary resolutions $N_B$ and $T_B$ of $N$ and $T$, respectively, such that $N_B$ displays $T_B$, that is, there is a subdivision $S_B$ of $T_B$ that is a subgraph of $N_B$. Let $\chi : V(N_B) \to V(N)$ be the function mapping each vertex $u$ in $N_B$ to the vertex $\chi(u)$ in $N$ that $u$ is contracted to when forming $N$. Note that, for all vertices $w \in V(N)$, the vertices in $\chi^{-1}(w)$ form a connected component in $N_B$. To show that, the vertices in $\chi^{-1}(w)$ also form a connected component in $S_B$, assume that there are vertices $u$ and $v$ in $S_B$ with $\chi(LCA_{S_B}(uv)) \neq \chi(v) = v$. Clearly, $u$ and $v$ are not in the ancestor relation in $S_B$. Further, by Observation 1, $\chi^{-1}(w)$ contains only reticulations and degree-two vertices or only tree vertices of $N_B$. Since $\chi^{-1}(w)$ induces a connected component in $N_B$, the latter case implies $\chi(LCA_{S_B}(uv)) = \chi(u) = \chi(v)$. In the former case, there is some $\gamma \in \chi^{-1}(w)$ with $\gamma < N_B uv$ (note that $\gamma \in uv$ contradicts $LCA_{S_B}(uv) \notin uv$) and, since $S_B$ is a tree, it cannot contain all edges between $\gamma$ and $u$ and $v$. Thus, $u$ or $v$ does not have a labeled leaf below it in $S_B$. The vertices in $\chi^{-1}(w)$ therefore form a connected component in $S_B$ for each $w \in V(N)$. Since (a) $\chi^{-1}(w)$ in $S_B$ is a subset of $\chi^{-1}(w)$ in $N_B$ and contracting it in $N_B$ yields $N$ and (b) $\chi^{-1}(w)$ is a connected component in $S_B$ it follows that the result $T'$ of contracting $\chi^{-1}(w)$ for each $w \in V(N)$ to a single vertex in $S_B$ is a subgraph of $N$. Furthermore, $S_B$ is a binary resolution of $T'$ displaying $T_B$, which is a binary resolution of $T$ and, by (c), $T'$ displays $T$.

$\Leftarrow$: By (c), there is a binary tree $T_B$ on $X$ displayed by both $T'$ and $T$. We construct a binary resolution $N_B$ of $N$ such that $N_B$ displays $T_B$ which, by Observation 2, is a binary resolution of $T$ (see Figure 1). To this end, let $T^*$ be any spanning subgraph of $N$ that is a tree and contains $T'$ as a subgraph, and let $Y := E(N) \setminus E(T^*)$ be the set of edges in $N$ that are missing in $T^*$. Since $T_B$ is a binary resolution of $T'$, there is a binary resolution $T_B^*$ of $T^*$ that contains a subdivision of $T_B$. Finally, we construct $N_B$ from $T_B^*$ by adding representations of all edges $uv \in Y$. To this end, let $\chi : V(T_B^*) \to V(T^*)$ be a function mapping each vertex $x$ of $T_B^*$ to a vertex of $T^*$ such that $T^*$ can be obtained from $T_B^*$ by contracting all edges $uv \in T_B^*$ with $\chi(u) = \chi(v)$. Note that $\chi$ is surjective. Let $uv \in Y$. In order to keep $T_B^*$ binary while adding a representation of $uv$, we will first create two new vertices $u_B$ and $v_B$ in $T_B^*$ and then add the edge $u_Bv_B$. If $|\chi^{-1}(u)| = 1$, then let $y$ be the unique vertex in $\chi^{-1}(u)$ and, if $y$ is the root of $T_B^*$, then add a new root $u_B$ to $T_B^*$, and make $y$ its only child, otherwise subdivide the edge between $y$ and its parent with a new vertex $u_B$. In both cases, add $u_B$ to $\chi^{-1}(u)$. If $|\chi^{-1}(u)| > 1$, then subdivide any edge between vertices in $\chi^{-1}(u)$, call the new vertex $u_B$ and add it to $\chi^{-1}(u)$. Then, construct a new vertex $v_B$ corresponding to $v$ in an analogous way and add the edge $u_Bv_B$. Let $N_B$ denote the result of repeating this operation for all edges $uv \in Y$. Since $N_B$ results from $T_B^*$ by a series of subdivisions and edge additions, we know that $N_B$ contains a subdivision of $T_B^*$ and, thus, displays $T_B$. It remains to show that $N_B$ is a binary resolution of $N$, that is, $N$ is a contraction of $N_B$. Indeed, we show that $N$ is equal to the result $N^*$ of contracting all $u,v \in V(N_B)$ with $\chi(u) = \chi(v)$. First, since $T^*$ spans $N$, the image of $\chi$ equals $V(N)$ and, thus, $V(N^*) = V(N)$. Second, assume that $N^*$ contains an edge $xy$ that is not in $N$ and, thus, not in $T^*$. But then, there is an edge $xy_B \in E(N_B^*)$ such that $\chi(xy) = x$ and $\chi(y_B) = y$. Since $xy$ is not in $T^*$, we know that $xy_B$ is not in $T_B^*$, so $xy_B$ has been added by the procedure above. By construction, there is an edge $uv \in N$ such that $x \in \chi^{-1}(u)$ and $y \in \chi^{-1}(v)$, implying that $u = x$ and $v = y$, contradicting $xy$ not being an edge of $N$. Third, assume that $N$ contains an edge $xy$ that is not in $N^*$. Then, $xy$ is not in $T^*$. Thus, by the construction above, $N_B$ contains vertices $x_B \in \chi^{-1}(x)$ and $y_B \in \chi^{-1}(y)$ such that $x_By_B$ is an edge of $N_B$. But then, $xy$ is an edge of $N^*$. □
Figure 2: Illustration of Lemma 4: (N, T) left and (N_1, T_1) right.

Note that, if N contains a subdivision S of T, then any reticulation in N that is in S has in- and out-degree one in S. Further, contracting an edge between two tree vertices of N cannot break softly displaying T.

**Observation 8.** Let N be a network that displays a tree T and let N' be the result of contracting an edge between two tree-vertices or two reticulations of N. Then, N' displays T.

Also note that, if N displays T, then the result of removing any label from N displays the result of removing this label from T.

**Observation 9.** Let N be a network and let T be a tree on X. Then, N displays T if and only if N|_{X'} displays T|_{X'} for each X' \subseteq X.

### 3 Single-Labeled Trees

In a first step, we suppose that N is a tree. While Lemma 1 already provides a means to solve this case in polynomial time, we aim to be more efficient. If N and T are both binary, this special case is solved using the folklore “cherry reduction”: remove a pair of leaves that are siblings in both N and T and label their parents in N and T with the same new label \( \lambda \). Here, we prove an analog for non-binary trees that allows solving the case that N is a tree in linear time.

**Lemma 4.** Let N be a network on X with root \( \rho_N \), let T be tree on X, let \( u_N \in V(N) \) and \( u_T \in V(T) \) and let \( C_N \) and \( C_T \) be sets of children of \( u_N \) and \( u_T \), respectively, such that

(a) \( \bigcup_{c \in C_N} \mathcal{L}(c) = \bigcup_{c \in C_T} \mathcal{L}(c) =: Y \), and

(b) for all \( \lambda \in Y \), all \( \rho_N \)-\( \lambda \)-paths contain some \( c \in C_N \).

Let \( \lambda \in Y \), let \( N_1 := N|_{X\setminus(\lambda\setminus\lambda)} \), let \( T_1 := T|_{X\setminus(\lambda\setminus\lambda)} \), let \( N_2 := N|_{Y} \), and let \( T_2 := T|_{Y} \). Then, N displays T if and only if \( N_1 \) displays \( T_1 \) and \( N_2 \) displays \( T_2 \).

**Proof.** Since \( \Rightarrow \) follows directly from Observation 9, we only show \( \Leftarrow \). By Lemma 3, for each \( i \in \{1, 2\} \), there is a tree \( Q_i \) in \( N_i \) (containing the root of \( N_i \)) that displays \( T_i \) and there is a binary tree \( T_i^B \) that is displayed by both \( Q_i \) and \( T_i \). We show that the binary tree \( T_B \) resulting from replacing the leaf \( \lambda \) in \( T_i^B \) by \( T_2^B \) is displayed by both \( T \) and a subtree \( Q \) of \( N \).

To this end, note that \( T \) is the result of replacing the leaf \( \lambda \) in \( T_1 \) by \( T_2 \) and let \( Q \) be the result of replacing the leaf \( \lambda \) in \( Q_1 \) by \( Q_2 \). Since \( T_i^B \) is displayed by both \( T_i \) and \( Q_i \) for all \( i \in \{1, 2\} \), the following argument holds for both \( T \) and \( Q \), but we only state it for \( T \). To show that \( T \) displays \( T_B \), it suffices to prove that \( T \) displays all triplets displayed by \( T_B \) (by Lemma 3(b)). Towards a contradiction, assume that \( T_B \) displays a triplet \( xy|z \) that \( T \) does not display.

**Case 1:** \( x, y \in Y \). If \( z \) is also in \( Y \), then \( xy|z \) is displayed by \( T_2^B \) and, thus, by \( T_2 \) and by \( T \). If \( z \notin Y \), then \( \text{LCA}_T(xy) \leq_T \text{LCA}_T(Y) \leq_T u_T \leq_T \{\text{LCA}_T(xz), \text{LCA}_T(yz)\} \) by (a) (and (b) when arguing for \( Q \) instead of \( T \)) and, by Lemma 3(a), \( T \) displays \( xy|z \).

**Case 2:** \( x \) or \( y \) is not in \( Y \). Without loss of generality, let \( x \notin Y \). If also \( y \notin Y \), then \( \lambda \) can take the role of \( z \) in the assumption, that is, \( T_B \) displays \( xy|\lambda \) but \( T \) does not. But then, \( T_2^B \) displays \( xy|\lambda \) but \( T_1 \) does not, contradicting the fact that \( T_1 \) displays \( T_B^B \). Thus, \( y \in Y \) and, completely analogously,
Finally, let $T^*$ be the result of contracting $\text{LCA}_Q(Y)$ (that is, the former root of $T^*_k$) onto its parent in $Q$. Then, $T^*$ is a subtree of $N$ since $N$ is (isomorphic to) the result of replacing $\ell$ by $N_2$ in $N_1$ and contracting the the root of $N_2$ onto its parent in the result. Since $Q$ displays $T_B$, so does $T^*$ (by Observation 8). Thus, $T^*$ is a subtree of $N$ that displays $T$ and, by Lemma 3(d) $N$ displays $T$. \hfill $\square$

In the following, the operation of splitting off a vertex $u$ in a network $N$ means to duplicate $u$, remove all incoming edges from one copy of $u$ and remove all outgoing edges from the other copy of $u$, thus giving rise to $N_1$ (where a copy of $u$ is a leaf) and $N_2$ (where a copy of $u$ is the root). Lemma 4 gives rise to the following reduction rule.

**Reduction Rule 1.** Let $(N,T)$ be an instance of Tree Containment, let $B$ be a lowest biconnected component or a cherry of $N$ with root $u$ such that $B$ does not consist of a leaf and a non-leaf. Then, split off $u$ from $N$, split-off $\text{LCA}_T(\mathcal{L}(u))$ from $T$, and give the new leaf in $N$ and $T$ the same new label $\lambda$.

Note that Reduction Rule 1 Further, note that the vertex $u$ is a cut-vertex in $N$. Thus, the biconnected components of $N$ are not modified by application of Reduction Rule 1 and, since biconnected components can be found in linear time [11], we conclude that Reduction Rule 1 can be exhaustively applied in linear time.

**Theorem 1.** **Weak Tree Containment** can be solved in linear time if $N$ and $T$ are trees.

## 4 Tree Containment in Multilabeled Trees

To show that Tree Containment is NP-hard even when restricting $N$ to be a multilabeled tree, we reduce from 2-Union Independent Set, which asks if a graph $(V,E_1 \cup E_2)$ has a size-$k$ independent set, and which is NP-hard even if $(V,E_1)$ is a collection of disjoint $K_{2s}$ (that is, a matching) and $(V,E_2)$ is a collection of disjoint $P_{2s}$ and $P_{3s}$ [15]. For our reduction, we allow $(V,E_2)$ to also contain $K_{3s}$ and demand that $k$ equals the number of cliques in $(V,E_1)$. To prove that this variant remains NP-hard, we slightly modify the reduction from 3-SAT given by van Bevern et al. [15].

**Construction 1.** Consider an instance $\varphi$ with $n$ variables $x_i$ and $m$ clauses $c_j$ of 3-SAT such that each variable occurs at least twice in $\varphi$ and at most once in each clause. For each variable $x_i$, let $J_i$ be the list of indices of clauses that contain $x_i$ or $\neg x_i$ and let $J_i[\ell]$ denote the $\ell$th element of this list. Construct a graph $(V,E)$ as follows. For each variable $x_i$, construct a cycle $V_i$ of $2|J_i|$ vertices: $(u^i_1, \overline{u}^i_1, u^i_2, \overline{u}^i_2, \ldots)$. For each clause $c_j$ on the variables $x_k, x_i, x_t$, construct a triangle $C_j = (w^j_1, w^j_k, w^j_t)$. For each variable $x_i$ and each $\ell \leq |J_i|$, connect $w^j_{J_i[\ell]}$ to $\overline{u}^i_\ell$ if $c_{J_i[\ell]}$ contains $x_i$, and to $u^i_\ell$ if $c_{J_i[\ell]}$ contains $\neg x_i$. Now, $(V,E_1)$ consist of all triangles and all edges $\{u^i_1, \overline{u}^i_1\}$ while $E_2$ contains all other edges. See Figure 3 for an illustration.

Note that $(V,E_1)$ consists of disjoint $K_{2s}$ and $K_{3s}$ and $(V,E_2)$ consist exclusively of $P_{2s}$. Also note that this generalizes to $k$-SAT but $(V,E_1)$ becomes a collection of disjoint $K_{2s}$ and $K_{k}$s.

**Lemma 5.** $\varphi$ is satisfiable if and only if $(V,E)$ has a size-$k$ independent set, where $k$ is the number of cliques in $(V,E_1)$.
Figure 4: Illustration of Construction 2. Left: the initial instance of 2-Union Independent Set with 4 colors (●, ●, ○, □) and a size-4 solution encircled. Right: the non-binary tree $T$ (boxes and triangles indicating label $i_1$ and $i_2$ for a color $i$). Middle: the binary multi-labeled tree $N$ with a subdivision of $T$ (bold, gray) corresponding to the solution to the left instance.

Proof. Note that $k$ equals the number of cliques in $(V, E_1)$, each clique contains at most one independent vertex, and all vertices in $(V, E)$ are incident with some edge in $E_1$. Therefore, $(V, E)$ contains a size-$k$ independent set, if and only if a largest independent set in $(V, E)$ contains exactly one vertex of each clique in $(V, E_1)$. We will first show that if $(V, E)$ contains an independent set of size $k$, then $\varphi$ is satisfiable and afterwards the other direction.

“$\Leftarrow$”: Let $I$ be an independent set of size $k$ in $(V, E)$. Then, for each $i$, $I$ contains either $u_i^1$ or $\overline{u}_i^1$. By construction of $V_i$, it holds that if $u_i^h \in I$ for some $h$, then $u_i^1, \overline{v}_i^h \in I$ for all $\ell \leq |J_i|$. Analogously, if $\overline{u}_i^h \in I$ for some $h$, then $\overline{u}_i^1, \overline{v}_i^h \in I$ for all $\ell \leq |J_i|$. Consider any vertex $w_i^h$ in the clause gadget that is in $I$. Then, $w_i^1$ has a unique neighbor in the variable gadget of $x_j$ which is either $u_i^h$ for some $h$ if $\lnot x_j$ occurs in clause $i$ or $\overline{u}_i^h$ otherwise. If the neighbor is $u_i^h$, then all vertices $\overline{u}_i^h$ with $1 \leq \ell \leq |J_j|$ are in $I$ and otherwise all vertices $u_i^h$.

We set $x_i$ to true if $u_i^1$ is in $I$ and to false if $\overline{u}_i^1$ is in $I$. Consider any clause $c_j$ in $\varphi$. The literal whose corresponding vertex is in $I$ is then set to true as its neighboring vertex $u$ is not in $I$ and $u$ has a neighbor $u_j^h$ for some $h$ if $x_i$ occurs in $c_j$ and a neighbor $\overline{u}_j^h$ for some $h$ if $\lnot x_i$ appears in $c_j$. Since each clause has at least one variable set to true, $\varphi$ is satisfiable.

“$\Rightarrow$”: We will now show that if $\varphi$ is satisfiable, then $(V, E)$ contains an independent set of size $k$. Let $\beta$ be a satisfying assignment for $\varphi$. We construct an independent set $I$ for $(V, E)$ as follows. For each $x_i$ and each $\ell \leq |J_i|$, the set $I$ contains the vertices $u_i^\ell$ and $\overline{v}_i^\ell$ if $\beta(x_i) = 1$, and the vertices $\overline{u}_i^\ell$ and $\overline{v}_i^\ell$, otherwise. For each clause $c_j$, we pick one literal that is satisfied by our assignment of the variables and put the corresponding vertex into $I$. Observe that $I$ is of size $k$ as exactly one vertex of each clique in $(V, E_1)$ is in $I$. Further, $I$ is independent since, in each variable gadget, we pick every second vertex and, if a vertex in a clause gadget is picked, then its neighbor in the corresponding variable gadget is not picked.

We reduce this version of 2-Union Independent Set to Soft Tree Containment for multilabeled trees. To this end, we use an equivalent formulation where each clique in $(V, E_1)$ is represented by a color. The problem then becomes the following: Given a vertex-colored collection of $P_3$s, select exactly one vertex per color such that all selected vertices are independent. Note that the number of occurrences of each color equals the size of its corresponding clique in $(V, E_1)$.

Construction 2 (See Figure 4). Given a vertex-colored collection $G$ of $P_3$s constructed by Construction 1, we construct a multi-labeled tree $N$ and a tree $T$ as follows. Construct $T$ by first creating a star that has exactly one leaf of each color occurring in $G$ and then, for each leaf $x$ with color $i$, adding two new leaves colored $i_1$ and $i_2$, respectively, and removing the color from $x$.

Construct $N$ from $G$ as follows: For each $P_3$ $(u, v, w)$ where black, gray, and white denote the colors of $u$, $v$, and $w$, respectively, construct the binary tree depicted on the right, where a box or a triangle colored $i$ represents color $i_1$ or $i_2$, respectively. Then, add any binary tree on $|V(G)|$ leaves and identify its leaves with the roots of the constructed subtrees. Notice $u, v, w \in V(G) \cap V(N)$. 

Lemma 6. Construction 2 is correct, that is, $N$ displays $T$ if and only if the given collection $G$ of $P_3$s has a colorful independent set using each color exactly once.

Proof. Note that $N$ is binary and let $k$ be the number of colors in $G$.

\(\Rightarrow\)\: Let $N$ display $T$, that is, $N$ contains a binary tree $S$ displaying $T$ which, by Lemma 3 is equivalent to $T$ displaying $S$. Consider any color $i$ occurring in $T$. Then, $S$ contains leaves $u_1$ and $u_2$ in $S$ labeled $i_1$ and $i_2$, respectively, and we denote their least common ancestor in $S$ by $u^i$. If $u_1$ and $u_2$ are neither siblings, nor in an uncle-nephew-relation\(^2\), then we modify $S$ to include the sibling/uncle of $u_1$ in $N$ instead of $u_2$. Thus, we do not lose generality by assuming that $u_1$ and $u_2$ are either siblings or in an uncle-nephew-relation. We show that the set $Q = \bigcup_{i} u^i$ is a size-$k$ colorful independent set in $G$. First, for each color $i$, we know that $S$ contains exactly one leaf labeled $i_1$ and one leaf labeled $i_2$, so $u^i$ is unique and, by construction of $N$, no two $u^i$ coincide, implying that $Q$ contains exactly one vertex of each color. Towards a contradiction, suppose that $Q$ is not independent in $G$, that is, there are colors $i$ and $j$ such that $u^i$ and $u^j$ are adjacent in $G$. Without loss of generality, $u^i$ is the center of a $P_3$ in $G$, implying that $S$ contains the subtree $(((j_1, j_2), i_1), i_2)$ (that is, a caterpillar with leaves labeled $j_1$, $j_2$, $i_1$, $i_2$ in preorder). But then, $j_1 i_1 i_2$ is displayed by $S$ but not by $T$, thereby contradicting Definition 1(b).

\(\Leftarrow\)\: Let $Q$ be a size-$k$ colorful independent set of $G$, let $L$ be the set of leaves that, for each $u \in Q$ of color $i$, contains the leaves labeled $i_1$ and $i_2$ in $N_u$, and let $S := N|_L$. Note that $S$ is a subgraph of $N$ and, as $N$ is binary, $S$ is a subdivision of a binary tree. Since $Q$ contains exactly one vertex of each color in $G$, we know that $S$ contains all labels that occur in $T$. By Definition 1(d), to show that $N$ displays $T$, it suffices to show that $S$ displays $T$. To this end, assume that $S$ displays a triplet $xy$ that $T$ does not display. Then Definition 1(a) lets us assume LCA$_T(xz) \prec_T$ LCA$_T(xy)$. By Definition 1(a), we have LCA$_S(i_1 i_j) \preceq_S$ LCA$_S(i_1 i_2)$. Then, $i_1$ and $i_2$ cannot form a cherry in $S$ and, thus, $S|_{(i_1, i_2, j_1, j_2)}$ is the subtree $(((j_1, j_2), i_1), i_2)$. By construction of $S$, this implies that $Q$ contains two vertices of a $P_3$ in $G$, one of color $i$ and one of color $j$, and the latter is in the middle, contradicting independence of $Q$ in $G$.

\(\square\)

Theorem 2. Soft Tree Containment is NP-hard, even if $N$ is a binary 3-labeled tree.

Note that the number of occurrences of each label in $N$ equals the number of occurrences of each color in $G$ which, in turn, equals the size of a largest clique in $(V, E_1)$ (instance of 2-UNION INDEPENDENT SET), which equals the size of a largest clause (instance of 3-SAT), we can state the following generalization of Theorem 2.

Corollary 1. For each $k$, $k$-SAT reduces to Soft Tree Containment on binary $k$-labeled trees. Further, CNF-SAT reduces to Soft Tree Containment on binary multilabeled trees.

Corollary 1 immediately raises the question of what happens in the case that $N$ is a 2-labeled tree and we address this question in Section 4.1. Note that, for Soft Tree Containment, the case that $N$ is a multilabeled tree reduces straightforwardly to the case that $N$ is a reticulation-visible network, simply by merging all leaves with the same label into one reticulation and adding a new child labeled $i$ to it.

Corollary 2. Soft Tree Containment is NP-hard on reticulation-visible networks, even if the maximum in-degree is three.

Theorem 2 and Corollary 2 stand in contrast with results for (Strong) Tree Containment, which is linear-time solvable in both cases [9, 17].

4.1 2-Labeled Trees

In the following, $N$ is a 2-labeled tree and $T$ is a (single-labeled) tree. To solve Tree Containment in this case, we compute a mapping $M : V(T) \rightarrow 2^{V(N)}$ such that $M(u)$ contains the at most two minima

\(^2\) Two vertices are in an uncle-nephew relation if the sibling of one is the parent of the other.
(with respect to $\leq_N$) among all vertices $v$ of $N$ such that $N_v$ displays $T_u$. If $N$ displays $T$, there is a single-labeled subtree $S$ of $N$ that displays $T$. If, for each $u \in V(T)$, we have $\text{LCA}_S(L(u)) \in M(u)$, then we call $S$ canonical for $T$. We show that such a canonical subtree always exists.

**Lemma 7.** $N$ displays $T$ if and only if $N$ has a canonical subtree for $T$.

**Proof.** As “$\Rightarrow$” is evident, we just prove “$\Leftarrow$”. To this end, let $S$ be a single-labeled subtree of $N$ that is a subdivision of $T$. If $S$ is not canonical, then there is some $u \in V(T)$ with $x := \text{LCA}_S(L(u)) \notin M(u)$. Since $S_x$ displays $T_u$, so does $N_x$. Thus, by definition of $M$, there is some $y \in M(u)$ with $y <_N x$ (recall that $x \notin M(u))$. But then, we can replace the subtree of $S$ rooted at $x$ with the unique $x$-$y$-path in $N$ and the subtree of $N_y$ displaying $T_u$. Iterating this construction yields a canonical subtree of $N$ for $T$. 

To compute $M$, we consider vertices $u \in V(T)$ and $\rho \in V(N)$ in a bottom-up manner, checking if $N_\rho$ displays $T_u$. For each $v \in V(T_u)$ with parent $p$ in $T_u$, each $x \in M(v)$ has at most one ancestor $y$ in $M(p)$ since $M$ contains only minima. For $v = u$, we let $y := \rho$. In both cases, we call the unique $x$-$y$-path in $N_\rho$ the ascending path of $x$. A crucial lemma about ascending paths is the following.

**Lemma 8.** Let $S$ be a canonical subtree of $N'$ for $T'$ and let $u, v \in V(T')$ not be siblings. Let $\text{LCA}_S(L(u))$ and $\text{LCA}_S(L(v))$ have ascending paths $r$ and $q$, respectively. Then, $r$ and $q$ are edge-disjoint.

**Proof.** Note that, if $u <_{T'} v$ then $\text{LCA}_S(L(p)) \leq_S \text{LCA}_S(L(v))$ where $p$ is the parent of $u$ in $T'$. Thus, the highest point of $r$ is below the lowest point of $q$ and the lemma holds. This allows us to suppose in the following that $u$ and $v$ are incomparable in $T'$.

Towards a contradiction, assume that there is a vertex $z \in V(S)$ that is internal vertex of both $r$ and $q$ and, hence, is an ancestor of both $u$ and $v$ in $T'$. Then, $\{u, v, L(z)\}$. Further, since $u$ and $v$ are not siblings, one of $u$ and $v$ has a parent $p <_{T'} \text{LCA}_{T'}(uv)$. Without loss of generality, let $p$ be the parent of $u$, implying $\{l(p) \supseteq L(u) \neq \emptyset \text{ and } L(z) \not\subseteq \text{LCA}_S(L(v))\}$. Since $S$ is canonical, we have $\text{LCA}_S(L(p)) \in M(p)$ and, thus, the ascending path $r$ of $u$ ends in $\text{LCA}_S(L(p))$. Hence, as $z$ is an internal vertex of $r$, it holds that $z <_S \text{LCA}_S(L(p))$, implying $\text{LCA}_S(L(p)) \not\subseteq \emptyset$. Since $S$ displays $T'$, the three established relations between $L(p)$ and $L(z)$ contradict Lemma 1. 

Clearly, $N$ displays $T$ if and only if $M(\rho_T) \not\subseteq \emptyset$, where $\rho_T$ is the root of $T$. Further, computation of $M(u)$ is trivial if $u$ is a leaf. Thus, in the following, we show how to compute $M(u)$ given $M(v)$ for all $v \in V(T_u) - u$.

In a first step, compute $N\rfloor_L$, where $L$ is the set of leaves of $N$ whose label occurs in $T_u$. Then, we know that $M(v) \subseteq V(N\rfloor_L)$ for all $v \in V(T_u)$. Second, we mark all vertices $\rho$ in $N\rfloor_L$ such that, for each child $u_i$ of $u$ in $T$, there is some $x_i \in M(u_i)$ with $x_i \leq_N \rho$. For each marked vertex $\rho$ in a bottom-up manner, we test whether $N_\rho$ displays $T_u$ using the following formulation as a 2-SAT problem\(^3\).

**Construction 3.** Construct $\varphi_{u \rightarrow \rho}$ as follows. For each $v \in V(T_u) - u$,

(i) for each $y \in M(v)$, introduce a variable $x_{v \rightarrow y}$,

(ii) add the clause $\bigoplus_{y \in M(v)} x_{v \rightarrow y}$ (recall that $|M(v)| \leq 2$).

(iii) if the parent $p$ of $v$ in $T_u$ is not $u$ then, for all $y \in M(v)$ and all $z \in M(p)$ with $y \neq_N z$, add the clause $x_{v \rightarrow y} \Rightarrow \neg x_{w \rightarrow z}$.

(iv) for each $w \in V(T_u) - u$ that is not a sibling of $v$ and each $y \in M(v)$ and each $z \in M(w)$ such that the ascending paths of $y$ and $z$ share an edge, add the clause $x_{v \rightarrow y} \Rightarrow \neg x_{w \rightarrow z}$.

By definition of $M(u)$ it holds that no two vertices in $M(u)$ can be in an ancestor-descendant relation. For this reason we can ignore all ancestors of a vertex $\rho$ that satisfies $\varphi_{u \rightarrow \rho}$.

**Lemma 9.** $\varphi_{u \rightarrow \rho}$ is satisfiable if and only if $N_\rho$ displays $T_u$.

\(^3\)Note that we are using the XOR operation ($(x \oplus y := (x \vee y) \cap (\neg x \vee \neg y)$) as well as implications ($(x \Rightarrow y) := (\neg x \vee y)$) in the construction, which can be formulated as clauses with two variables as shown.
Proof. “⇌”: Let $S$ be a canonical subtree of $N_ρ$ for $T_u$ and let $β$ be an assignment for $φ_{u→ρ}$ that sets each $x_{v→y}$ to 1 if and only if $y = \text{LCA}_S(\mathcal{L}(v))$. Since the LCA of $\mathcal{L}(v)$ in $S$ is unique, all clauses of type (ii) are satisfied by $β$. If a clause of type (iii) is not satisfied, then there is some $v$ with parent $p$ in $T_u$ such that $y ≤_N z$ for some $y ∈ M(v)$ and $z ∈ M(p)$ and $β(x_{v→y}) = 1$ and $β(x_{p→z}) = 0$. Let $z’ ∈ M(p) − z$ with $β(x_{p→z'}) = 1$, which exists since all clauses of type (ii) are satisfied. Since $\mathcal{L}(p) ⊇ \mathcal{L}(v)$, we know that $y ≤_S z’$ and, as $S$ is a subtree of $N$, we have $y ≤_N z’$, implying $z ≤_N z’$ or $z’ ≤_N z$, which contradicts the construction of $M$. If a clause of type (iv) is not satisfied, then there are $x_{v→y}$ and $x_{u→z}$ such that $v$ and $w$ are not siblings in $T$, $β(x_{v→y}) = β(x_{u→z}) = 1$, and the ascending paths of $y = \text{LCA}_S(\mathcal{L}(v))$ and $z = \text{LCA}_S(\mathcal{L}(w))$ share an edge. But this contradicts Lemma 8.

“⇒”: Let $β$ be a satisfying assignment for $φ_{u→ρ}$. Let $ψ : T × V(N) → T$ be a relation such that $(v, y) ∈ ψ$ if and only if $β(x_{v→y}) = 1$. Since $β$ satisfies the clauses of type (ii), $ψ$ describes a function and, slightly abusing notation, we call this function $ψ$. Let $Y$ be the image of $ψ$ and let $S := N_{|y∈Y}$. Note that, for all $v ≤_T u$ with parent $p ≠ u$, we know that $ψ(v) ≤_N ψ(p)$, since $β$ satisfies the clauses of type (iii). Thus, for all $v, w ∈ V(T_u) − u$, we have

\[
\text{w} ≤_T \text{v} ⇒ ψ(\text{w}) ≤_N ψ(\text{v}) ⇒ ψ(\text{w}) ≤_S ψ(\text{v})
\]

(1)

We show for all $(v, y) ∈ ψ ∪\{(u, ρ)\}$ that $y = \text{LCA}_S(\mathcal{L}(v))$ and $S_y$ is a canonical subtree of $N_y$ for $T_u$. The proof is by induction on the height of $v$ in $T$. Clearly, if $v$ is a leaf, $y$ is a leaf with the same label and the claim follows. Otherwise, suppose that the claim holds for all $w <_T v$. Towards a contradiction, assume that $S_y$ does not display $T_v$. By Lemma 1, there are $w ∈ V(T_v)$ and $z ∈ V(S_y)$ such that there are leaves $a ∈ \mathcal{L}(z) \setminus \mathcal{L}(w)$, $b ∈ \mathcal{L}(w) \setminus \mathcal{L}(z)$, and $c ∈ \mathcal{L}(w) \cap \mathcal{L}(z)$. Note that $\text{LCAT}(bc) ≤_T w <_T \{\text{LCAT}(ab), \text{LCAT}(ac)\}$. Let $α$ be the highest ancestor of $a$ in $T$ with $b α T α$ and let $p_α$ be its parent in $T$. Let $γ$ be the highest ancestor of $c$ in $T$ with $b γ T γ$ and let $p_γ$ be its parent in $T$. Since $b, c <_T w$ and $a α T w$, we know that $p_γ <_T p_α$, implying that $α$ and $γ$ are not siblings in $T$. Then, as $\text{LCAT}(ac) ≤_S z ≤_S \{\text{LCAT}(ab), \text{LCAT}(bc)\}$ and $\text{LCAT}(bc) ≤_S ψ(p_γ)$, we know that the ascending paths of $ψ(α)$ and $ψ(γ)$ share an edge, contradicting (iv).

Theorem 3. On 2-labeled trees, SOFT TREE CONTAINMENT can be solved in $O(n^3)$ time.

Proof. As correctness follows from Lemma 9, we only show the running time. To this end, note the $N|L|$ can be computed in $O(|L|) = O(|\mathcal{L}(u)|)$ time (see, for example [3, Section 8]). To mark all vertices of $N|L|$ that, for each child $u_i$ of $u$ in $T$, have an ancestor in $M(u_i)$, we compute the restriction of $N|L|$ to $\bigcup_i M(u_i)$. Again, this can be done in linear time, that is, $O(\text{deg}_T(u))$. For each vertex in this restriction, we can store the set of leaves that descend from it. In a bottom-up manner, we can thus mark the correct vertices in $O(\text{deg}_T(u)^2)$ time.

We construct $φ_{u→ρ}$ for each pair $(u, ρ)$ as follows. To check $y ≤_N z$ efficiently in Construction 3(iii), we can prepare a 0/1-matrix with an entry for each pair of vertices in $N$. This table has size $O(n^2)$ and can be computed in the same time by a simple bottom-up scan of $N$. To construct the clauses of type (iv), we first order the vertices in $N_ρ$. For each $v$ in this order, we construct its ascending path in $O(|N_ρ|)$ time and store $v$ in all edges on this path. Thus, when constructing the clauses of type (iv) for a vertex $v$, we can merge the lists of vertices whose ascending path shares an edges with that of $v$. Thus, $φ_{u→ρ}$ can be constructed and solved in $O(|N_ρ|^2) = O(|\mathcal{L}(u)|^2)$ time and the total time to decide whether $N$ displays $T$ is $O(∑_{u∈V(T)} |\mathcal{L}(u)|^2) = O(n^3)$.

Theorem 3 implies 4 that we can solve bifurcating reticulation-visible networks in polynomial time, complementing Corollary 2.

Corollary 3. SOFT TREE CONTAINMENT can be solved in $O(n^3)$ time on reticulation-visible networks of in-degree at most two.

---

4See [17] for the corresponding reduction.
Remarks: in practice, it will be much faster to not consider the whole subtree $N|_L$ but only $N|_Q$ where $Q := \bigcup_i M(u_i)$. In general though, vertices of $Q$ might be mutually incompatible, that is, two children $u_1$ and $u_2$ of $u$ might map to $y_1 \in M(u_1)$ and $y_2 \in M(u_2)$ with $y_1 \leq_N y_2$. If this occurs, it is unclear whether or not both $T_{u_1}$ and $T_{u_2}$ can be displayed by $N|_{y_2}$ at the same time or not, as this depends on the ascending paths of the vertices in $N$ that the children of $u_1$ and $u_2$ map to. Thus, we would have to “develope” $y_1$ and $y_2$, where developing $y_1$ means to replace $y_1$ with the subtree rooted at $y_1$ restricted to $\bigcup_i M(u_{1,i})$ where $u_{1,i}$ are the children of $u_1$ in $T$. In theory, we might face another incompatibility at the level of the children of $u_1$ and this may, in theory, continue down to the leaves of $T$. Thus, in a worst-case consideration, we can just start with the full subtree $N|_L$ while in practice, the above strategy of developing incompatibilities will be much faster.
