Abstract

In the present work, we deal with the convergence of cell-centered nonlinear finite volume schemes for anisotropic and heterogeneous diffusion operators. A general framework for the convergence study of finite volume methods is provided and used to establish the convergence of the new methods. Thorough assessment on a set of anisotropic heterogeneous problems as well as a comparison with linear finite volume schemes is provided.

Keywords: monotone, finite volume methods, heterogeneous anisotropic diffusion, multi-point flux approximation, convergence analysis

1. Introduction

In a variety of physical problems, as for example multi-phase flow in porous media, efficient and robust schemes are required for the discretization of Darcy-type equations. One of the key ingredients for the numerical solution of this type of equations is the discretization of anisotropic heterogeneous elliptic terms [1] on highly complex unstructured grids. In order to maintain mass conservation, the most commonly used schemes applied to Darcy-type equations are either cell-centered finite volume methods, such as multi-point flux approximation methods (MPFA) [2, 3, 4, 5, 6, 7], or mixed and hybrid schemes, such as the mixed finite element (MFE) [8, 9], the mimetic finite difference (MFD) [10, 11] or the hybrid finite volume schemes (HFV) [12, 13]. These mixed or hybrid methods introduce additional face unknowns, whereas MPFA schemes use interpolation rules to eliminate these additional degrees of freedom.

None of these schemes are unconditionally monotone for general heterogeneous and anisotropic elliptic terms and grids. For example, it is proven in [14] that there exist no linear higher-order unconditionally monotone control-volume schemes. Monotone schemes are not only desirable in

terms of reliability, but also because of the improved robustness. Thinking of highly nonlinear coupled partial differential equations, where secondary variables are calculated using physical laws and relationships that non-linearly depend on primary variables, unphysical solutions can cause convergence problems of linear and nonlinear solvers during the simulation run. Relaxation of the linearity requirement of the schemes allows the construction of nonlinear monotone finite volume schemes. The first concepts of positivity-preserving or discrete extremum-principles-preserving schemes have been presented in [15, 16, 17, 18].

In this article, the proof of convergence of a family of numerical methods is given. The proof relies on concepts that have been developed in [4]. It generalizes the one given in [19] and allows to prove the convergence for the nonlinear finite volume schemes introduced in [15, 16, 17, 18, 20, 21] for which no proof yet existed, as mentioned in [22].

This work is organized as follows: In Section 2, a generic finite volume framework is given, including the proof of convergence under some hypotheses. In Section 3, this framework is used to prove the convergence for a specific family of discretizations. The idea of schemes belonging to this family is the construction of face flux approximations as a convex combination of consistent linear approximations. In Section 4, two representatives of this family, a nonlinear two-point flux approximation (NLTPFA) and a nonlinear multi-point flux approximation (NLMPFA), are derived. These approximations are constructed such that the NLTPFA scheme is monotone and the NLMPFA satisfies discrete extremum principles. Furthermore, sufficient conditions are derived to guarantee the strong consistency of the fluxes. Additionally, possible face interpolators, for which the convergence theory holds, are presented. These schemes are compared to linear ones in Section 5. In the first part 5.1, the convergence of the schemes is analyzed for a mildly and highly anisotropic test case on unstructured grids. In the second part 5.2, the schemes are tested for the extremum-principle-preservation property and it is demonstrated that linear schemes produce negative solution values, in contrast to nonlinear ones. In the last part of Section 5, the linearity-preservation property is investigated and the Northeast German Basin serves as a benchmark problem.

2. Abstract framework

In this section, we present a generic finite volume framework, following ideas that have been introduced in [4]. In Section 2.1, we define the model problem together with generic finite volume discretization schemes. In Section 2.2, proof of convergence of these schemes is given. Furthermore, the existence of discrete solutions is discussed in Section 2.3.

47 *2.1. Model problem and finite volume discretization*

48 Let $\Omega \subset \mathbb{R}^d$, $d \in \mathbb{N}^*$, be an open bounded connected polygonal domain with boundary $\partial\Omega$. Let
 49 Λ be a symmetric tensor-valued function such that (s.t.) there exist $0 < \alpha_0 < \beta_0 < +\infty$ so that,
 50 for almost every (a.e.) $x \in \overline{\Omega}$, the spectrum of $\Lambda(x)$ is contained in $[\alpha_0, \beta_0]$. In the following, the
 51 problem

$$\begin{cases} \nabla \cdot (-\Lambda \nabla \bar{u}) = f & \text{in } \Omega, \\ \bar{u} = 0 & \text{on } \partial\Omega, \end{cases} \quad (1)$$

52 is considered, where $f \in L^r(\Omega)$ with $r > 1$ if $d = 2$ and $r = \frac{2d}{d+2}$ if $d > 2$. The existence and
 53 uniqueness of a weak solution $\bar{u} \in H_0^1(\Omega)$ of problem (1) is a classical result.

54 *Remark 1.* Other standard types of boundary conditions can be considered. However, for ease of
 55 presentation, homogeneous Dirichlet conditions are considered within this section.

56 In what follows, the definition of finite volume discretizations for problem (1) and a generic
 57 framework covering fairly general (possibly non-conforming) polygonal meshes is provided.

58 **Definition 1** (Admissible family of discretizations). *An admissible family of finite volume dis-*
 59 *cretizations $\{\mathcal{D}_n\}_{n \in \mathbb{N}}$ is a triplet $\mathcal{D}_n = (\mathcal{T}_n, \mathcal{E}_n, \mathcal{P}_n)$, where*

60 (i) $\mathcal{T}_n$ is a finite family of non-empty connected open disjoint subsets of Ω (the cells or control
 61 volumes) s.t. $\overline{\Omega} = \bigcup_{K \in \mathcal{T}_n} \overline{K}$. For all $K \in \mathcal{T}_n$, we denote by $m_K > 0$ its d -dimensional measure
 62 (the volume) and let $\partial K \stackrel{\text{def}}{=} \overline{K} \setminus K$;

63 (ii) $\mathcal{E}_n$ is a finite family of subsets of $\overline{\Omega}$ (the faces) s.t., for all $\sigma \in \mathcal{E}_n$, σ is a non-empty closed
 64 subset of a hyperplane of $\mathbb{R}^d$ with $(d-1)$ -dimensional measure $m_\sigma > 0$ (the area), and s.t.
 65 the intersection of two different faces has zero $(d-1)$ -dimensional measure. We assume that,
 66 for all $K \in \mathcal{T}_n$, there exists a subset $\mathcal{E}_K$ of $\mathcal{E}_n$ such that $\partial K = \bigcup_{\sigma \in \mathcal{E}_K} \sigma$. For a given $\sigma \in \mathcal{E}_n$,
 67 either $\mathcal{T}_\sigma \stackrel{\text{def}}{=} \{K \in \mathcal{T}_n \mid \sigma \in \mathcal{E}_K\}$ has exactly one element and then $\sigma \subset \partial\Omega$ (boundary face)
 68 or $\mathcal{T}_\sigma$ has exactly two elements (inner face); the sets of inner and boundary faces are denoted
 69 by $\mathcal{E}_{n,\text{int}}$ and $\mathcal{E}_{n,\text{ext}}$ respectively;

70 (iii) $\mathcal{P}_n = \{x_K\}_{K \in \mathcal{T}_n}$ is a family of points of Ω indexed by $\mathcal{T}_n$ (the cell centers, not required to
 71 be the barycenters) s.t. $x_K \in K$ and K is star-shaped with respect to x_K . For all $K \in \mathcal{T}_n$
 72 and for all $\sigma \in \mathcal{E}_K$ we denote by $d_{K,\sigma}$ the Euclidean distance between x_K and the hyperplane
 73 supporting σ . We suppose that there exist $0 < \varrho_1, \varrho_2, \varrho_3 < +\infty$ independent of n s.t.

$$\min_{K \in \mathcal{T}_n, \sigma \in \mathcal{E}_K} \frac{d_{K,\sigma}}{\text{diam}(K)} \geq \varrho_1, \quad \min_{\sigma \in \mathcal{E}_{n,\text{int}}, \mathcal{T}_\sigma = \{K, L\}} \frac{\min(d_{K,\sigma}, d_{L,\sigma})}{\max(d_{K,\sigma}, d_{L,\sigma})} \geq \varrho_2, \quad \min_{K \in \mathcal{T}_n} \frac{\text{diam}(K)}{h_{\mathcal{D}_n}} \geq \varrho_3, \quad (2)$$

74 where $h_{\mathcal{D}_n}$ denotes the size of the discretization defined by $h_{\mathcal{D}_n} \stackrel{\text{def}}{=} \sup_{K \in \mathcal{T}_n} \text{diam}(K)$.

Figure 1: An example of admissible mesh for $d = 2$.

Figure 1 presents an example of an admissible mesh in two space dimensions. With items (ii) and (iii), and since $\frac{m_\sigma d_{K,\sigma}}{d}$ is the measure of the convex hull $\triangle_{K,\sigma}$ of x_K and σ , it is inferred that

$$\forall K \in \mathcal{T}_n, \quad \sum_{\sigma \in \mathcal{E}_K} m_\sigma d_{K,\sigma} = d m_K. \quad (3)$$

For all $K \in \mathcal{T}_n$ and $\sigma \in \mathcal{E}_K$, we denote the unit vector that is normal to σ and outward to K with the term $\mathbf{n}_{K,\sigma}$. For all $K \in \mathcal{T}$ and for all $\Phi \in L^1(K)$, we set $\langle \Phi \rangle_K \stackrel{\text{def}}{=} m_K^{-1} \int_K \Phi dx$. For vectorial functions, this notation is meant component-wise. For all vectors $x \in \mathbb{R}^n$, $n \in \mathbb{N}^*$, the Euclidean norm will be denoted by $|x| \stackrel{\text{def}}{=} \sqrt{x \cdot x}$; for all matrices $A \in \mathbb{R}^n \times \mathbb{R}^n$, $n \in \mathbb{N}^*$, we shall denote by $|A|$ the norm induced by the scalar product of $\mathbb{R}^n$, i.e., $|A| \stackrel{\text{def}}{=} \sup_{x \in \mathbb{R}^d} \frac{|Ax|}{|x|}$. The vector space of bounded linear operators from E to F will be denoted by $\mathcal{L}(E; F)$.

In what follows, when referring to a generic element $\mathcal{D}_n$ of an admissible family of discretizations $\{\mathcal{D}_n\}_{n \in \mathbb{N}}$, the subscript n will be dropped for the ease of reading in the case that no ambiguity arises. The space of piecewise constant functions on $\mathcal{T}$ is defined as

$$H_{\mathcal{T}}(\Omega) \stackrel{\text{def}}{=} \{v \in L^2(\Omega) \mid v|_K \in \mathbb{P}^0(K), \forall K \in \mathcal{T}\}.$$

For all $v \in H_{\mathcal{T}}$ and for all $K \in \mathcal{T}$, v_K will denote the (constant) value of v on K , i.e., $v|_K(x) = v_K$ for all $x \in K$. In order to endow $H_{\mathcal{T}}$ with a discrete H^1 norm, it is equipped with the following norm

$$\|v\|_{\mathcal{T}} \stackrel{\text{def}}{=} \left(\sum_{K \in \mathcal{T}} \sum_{\sigma \in \mathcal{E}_K} \frac{m_\sigma}{d_{K,\sigma}} |\gamma_\sigma v - v_K|^2 \right)^{1/2},$$

where $\gamma_\sigma \in \mathcal{L}(H_{\mathcal{T}}(\Omega); \mathbb{P}^0(\sigma))$ is defined as

$$\forall v \in H_{\mathcal{T}}(\Omega), \quad \begin{cases} \gamma_\sigma v = \frac{d_{L,\sigma} v_K + d_{K,\sigma} v_L}{d_{K,\sigma} + d_{L,\sigma}} & \text{if } \sigma \in \mathcal{E}_{\text{int}} \text{ with } \mathcal{T}_\sigma = \{K, L\}, \\ \gamma_\sigma v = 0 & \text{if } \sigma \in \mathcal{E}_{\text{ext}}. \end{cases}$$

Let $a_{\mathcal{T}}(u, v, w)$ be a form defined for all $(u, v, w) \in [H_{\mathcal{T}}(\Omega)]^3$. In what follows, discretizations for (1) of the form

$$\text{Find } u \in H_{\mathcal{T}}(\Omega) \text{ s.t. } a_{\mathcal{T}}(u, u, v) = \int_{\Omega} f v dx \quad \text{for all } v \in H_{\mathcal{T}}(\Omega) \quad (4)$$

are considered.

94 *Remark 2.* Any conservative finite volume scheme is equivalent to a discrete problem of type (4).
 95 For all $K \in \mathcal{T}$, and for all $\sigma \in \mathcal{E}_K$, let $F_{K,\sigma} : H_{\mathcal{T}}(\Omega) \times H_{\mathcal{T}}(\Omega) \mapsto \mathbb{P}^0(\sigma)$ be a numerical flux
 96 function meant to approximate the diffusive flux flowing out of K through σ such that the finite
 97 volume scheme reads: For all $K \in \mathcal{T}$,

$$-\sum_{\sigma \in \mathcal{E}_K} F_{K,\sigma}(u, u) = \int_K f \, dx, \quad (5)$$

98 with locally conservative fluxes: for all $(u, v) \in H_{\mathcal{T}}(\Omega) \times H_{\mathcal{T}}(\Omega)$, $\sigma \in \mathcal{E}_{\text{int}}$ and $\mathcal{T}_\sigma = \{K, L\}$,

$$F_{K,\sigma}(u, v) + F_{L,\sigma}(u, v) = 0. \quad (6)$$

99 Then, for all $v \in H_{\mathcal{T}}(\Omega)$, by multiplying equation (5) with v_K , $K \in \mathcal{T}$, summing up the
 100 resulting equation over $K \in \mathcal{T}$, we obtain for any $v \in H_{\mathcal{T}}(\Omega)$,

$$-\sum_{K \in \mathcal{T}} \sum_{\sigma \in \mathcal{E}_K} F_{K,\sigma}(u, u) v_K = \int_{\Omega} f v \, dx. \quad (7)$$

101 Thus, for all $(u, v, w) \in [H_{\mathcal{T}}(\Omega)]^3$, we define the form

$$a_{\mathcal{T}}(u, v, w) \stackrel{\text{def}}{=} -\sum_{K \in \mathcal{T}} \sum_{\sigma \in \mathcal{E}_K} F_{K,\sigma}(u, v) w_K. \quad (8)$$

102 Then, thanks to (7) and (8), we obtain a discrete problem of type (4) with $a_{\mathcal{T}}$ defined by (8). Fur-
 103 thermore, starting from the discrete problem (4) with $a_{\mathcal{T}}$ defined by (8), equation (5) is obtained
 104 by taking for each $K \in \mathcal{T}$, $v_K = 1$ and $v_{K'} = 0$ for all $K' \in \mathcal{T}$ s.t. $K' \neq K$.

105 *Remark 3.* One can also easily verify that the discrete problem of type (4) is equivalent to the
 106 problem: Find $u \in H_{\mathcal{T}}(\Omega)$ such that for all $K \in \mathcal{T}$

$$\mathbb{A}_{\mathcal{T}}(u) = \int_K f \, dx,$$

107 where the function $\mathbb{A}_{\mathcal{T}} : v \mapsto \mathbb{A}_{\mathcal{T}}(v)$, a mapping from $H_{\mathcal{T}}(\Omega)$ to $H_{\mathcal{T}}(\Omega)$, is defined as

$$(\mathbb{A}_{\mathcal{T}}(v))_K \stackrel{\text{def}}{=} a_{\mathcal{T}}(v, v, \mathbf{1}_K), \quad (9)$$

108 for each $K \in \mathcal{T}$, where $\mathbf{1}_K$ is the element of $H_{\mathcal{T}}(\Omega)$ equal to one on K and zero elsewhere.

109 Finally, we introduce the discrete gradient $\tilde{\nabla}_{\mathcal{D}} \in \mathcal{L}(H_{\mathcal{T}}(\Omega); [H_{\mathcal{T}}(\Omega)]^d)$ which is defined such
 110 that for all $K \in \mathcal{T}$ and all $v \in H_{\mathcal{T}}(\Omega)$,

$$\tilde{\nabla}_{\mathcal{D}} v|_K = \frac{1}{m_K} \sum_{\sigma \in \mathcal{E}_K} m_{\sigma} (\gamma_{\sigma} v - v_K) \mathbf{n}_{K,\sigma}. \quad (10)$$

111 For all $v \in H_{\mathcal{T}}$ and for all $K \in \mathcal{T}$, $(\tilde{\nabla}_{\mathcal{D}} v)_K$ will denote the (constant) value of $\tilde{\nabla}_{\mathcal{D}} v$ on K ,
 112 i.e., $\tilde{\nabla}_{\mathcal{D}} v|_K(x) = (\tilde{\nabla}_{\mathcal{D}} v)_K$ for all $x \in K$. Let us notice that Equation (3) together with the
 113 Cauchy-Schwarz inequality yield

$$\|\tilde{\nabla}_{\mathcal{D}} v\|_{[L^2(\Omega)]^d} \leq \sqrt{d} \|v\|_{\mathcal{T}} \quad \forall v \in H_{\mathcal{T}}(\Omega). \quad (11)$$

114 2.2. Convergence analysis

115 The aim of this section is to carry out a convergence analysis for finite volume schemes of type
 116 (4) by assuming the following properties of the form $a_{\mathcal{T}}(u, v, w)$.

117 **Hypotheses 1.** Let $\{\mathcal{D}_n\}_{n \in \mathbb{N}}$ be a family of discretizations matching Definition 1 s.t. $h_{\mathcal{D}_n} \rightarrow 0$
 118 as $n \rightarrow \infty$. Let $\mathfrak{D}$ be a dense subspace of $H_0^1(\Omega)$ s.t. $\mathfrak{D} \subset C_0(\overline{\Omega})$, where $C_0(\overline{\Omega})$ denotes the space
 119 of continuous functions which vanish on $\partial\Omega$. For all $\varphi \in \mathfrak{D}$, we denote by $\varphi_{\mathcal{T}_n}$ the element of
 120 $H_{\mathcal{T}_n}(\Omega)$ s.t., for all $K \in \mathcal{T}_n$, $\varphi_{\mathcal{T}_n}|_K = \varphi(\mathbf{x}_K)$. We suppose that:

121 (P1) for any $v \in H_{\mathcal{T}_n}(\Omega)$, $v \mapsto a_{\mathcal{T}_n}(v, \cdot, \cdot)$ is a bilinear form;

122 (P2) $a_{\mathcal{T}_n}$ is uniformly coercive, i.e., there is $0 < \gamma_1 < +\infty$ independent of n s.t.

$$\forall (u, v) \in H_{\mathcal{T}_n}(\Omega) \times H_{\mathcal{T}_n}(\Omega), \quad a_{\mathcal{T}_n}(u, v, v) \geq \gamma_1 \|v\|_{\mathcal{T}_n}^2;$$

123 (P3) $a_{\mathcal{T}_n}$ is weakly consistent on $\mathfrak{D}$, i.e., for all $\varphi \in \mathfrak{D}$,

$$\epsilon_{\mathcal{D}_n}(\varphi) \stackrel{\text{def}}{=} \max_{(u, v) \in [H_{\mathcal{T}_n}(\Omega)]^2, v \neq 0} \frac{1}{\|v\|_{\mathcal{T}_n}} \left| a_{\mathcal{T}_n}(u, \varphi, v) - \int_{\Omega} \Lambda \nabla \varphi \cdot \tilde{\nabla}_{\mathcal{D}_n} v \, dx \right| \rightarrow 0 \text{ as } n \rightarrow \infty. \quad (12)$$

124 *Remark 4.* Owing to (3), for a form $a_{\mathcal{T}_n}$ such as (8) derived from a conservative finite volume
 125 method, Property (P3) holds for strongly consistent numerical fluxes, i.e. fluxes, for which there
 126 is $0 < C_1 < +\infty$ independent of n , s.t. for all $\varphi \in \mathfrak{D}$,

$$\forall K \in \mathcal{T}_n, \forall \sigma \in \mathcal{E}_K, \quad \max_{u \in H_{\mathcal{T}_n}(\Omega)} |F_{K, \sigma}(u, \varphi_{\mathcal{T}_n}) - m_{\sigma} \langle \Lambda \nabla \varphi \rangle_{K \cdot \mathbf{n}_{K, \sigma}}| \leq C_1 m_{\sigma} h_{\mathcal{D}_n}. \quad (13)$$

127 Indeed, thanks to the conservation of the fluxes (6), after inserting for each $\sigma \in \mathcal{E}_{\text{int}}$, $\gamma_{\sigma} v$ in the
 128 expression of $a_{\mathcal{T}_n}(u, \varphi, v)$ given by (8), we get

$$a_{\mathcal{T}_n}(u, \varphi, v) = \sum_{K \in \mathcal{T}_n} \sum_{\sigma \in \mathcal{E}_K} F_{K, \sigma}(u, \varphi_{\mathcal{T}_n})(\gamma_{\sigma} v - v_K). \quad (14)$$

129 Furthermore, using (10), we have

$$\int_{\Omega} \Lambda \nabla \varphi \cdot \tilde{\nabla}_{\mathcal{D}_n} v \, dx = \sum_{K \in \mathcal{T}_n} \sum_{\sigma \in \mathcal{E}_K} m_{\sigma} \langle \Lambda \nabla \varphi \rangle_{K \cdot \mathbf{n}_{K, \sigma}} (\gamma_{\sigma} v - v_K). \quad (15)$$

130 Hence, by taking the difference between (14) and (15), using (13) and Cauchy-Schwarz inequality
 131 along with (3), we deduce that $\epsilon_{\mathcal{D}_n}(\varphi) \leq C_1 \sqrt{d m_{\Omega}} h_{\mathcal{D}_n}$, leading to (P3).

132 The main result of this section is stated in the theorem below.

133 **Theorem 1** (Convergence). *Let us assume that Hypotheses 1 hold and that for each $n \in \mathbb{N}$, there*
 134 *exists at least one solution $u_n \in H_{\mathcal{D}_n}(\Omega)$ to the problem (4). Then, as $n \rightarrow \infty$, the sequence of*
 135 *discrete solutions of problem (4), denoted as $\{u_n\}_{n \in \mathbb{N}}$, converges to the solution $\bar{u}$ of (1) in $L^q(\Omega)$*
 136 *for all $q \in [1, 2d/(d-2))$ (and weakly in $L^{2d/(d-2)}(\Omega)$ if $d > 2$).*

137 *Proof.* The proof is based on a few technical propositions which are reminded in Section 7. Owing
 138 to the stability estimate (68) together with Theorem 2, there is $\tilde{u} \in H_0^1(\Omega)$ s.t., up to a subsequence,
 139 (i) $\{u_n\}_{n \in \mathbb{N}}$ converges to $\tilde{u}$ in $L^q(\Omega)$ for all $q \in [1, 2d/(d-2))$ (and weakly in $L^{2d/(d-2)}(\Omega)$ if $d > 2$)
 140 and (ii) $\{\tilde{\nabla}_{\mathcal{D}_n} u_n\}_{n \in \mathbb{N}}$ weakly converges to $\nabla \tilde{u}$ in $[L^2(\Omega)]^d$. It only remains to prove that $\tilde{u} = \bar{u}$.
 141 Let $\varphi \in \mathfrak{D}$. Owing to (11) together with (P2) and (P1), we infer

$$\|\tilde{\nabla}_{\mathcal{D}_n}(u_n - \varphi_{\mathcal{T}_n})\|_{[L^2(\Omega)]^d}^2 \leq d \|u_n - \varphi_{\mathcal{T}_n}\|_{\mathcal{T}_n}^2 \leq \frac{d}{\gamma_1} a_{\mathcal{T}_n}(u_n, u_n - \varphi_{\mathcal{T}_n}, u_n - \varphi_{\mathcal{T}_n}) = \frac{d}{\gamma_1} (T_1 + T_2), \quad (16)$$

142 where $T_1 \stackrel{\text{def}}{=} \int_{\Omega} f(u_n - \varphi_{\mathcal{T}_n}) dx$ and $T_2 \stackrel{\text{def}}{=} a_{\mathcal{T}_n}(u_n, \varphi_{\mathcal{T}_n}, \varphi_{\mathcal{T}_n} - u_n)$. Since $f \in L^r(\Omega)$ and $\{u_n\}_{n \in \mathbb{N}}$
 143 weakly converges towards $\tilde{u}$ in $L^q(\Omega)$ for all $q < +\infty$ if $d = 2$ and for all $q = \frac{2d}{d-2}$ if $d > 2$, we have
 144

$$T_1 \rightarrow \int_{\Omega} f(\tilde{u} - \varphi) dx \text{ as } n \rightarrow \infty. \quad (17)$$

145 Furthermore, we have

$$\begin{aligned} a_{\mathcal{T}_n}(u_n, \varphi_{\mathcal{T}_n}, u_n) &= \left(a_{\mathcal{T}_n}(u_n, \varphi_{\mathcal{T}_n}, u_n) - \int_{\Omega} \Lambda \nabla \varphi \cdot \tilde{\nabla}_{\mathcal{D}_n} u_n dx \right) \\ &\quad + \int_{\Omega} \Lambda \nabla \varphi \cdot \tilde{\nabla}_{\mathcal{D}_n} u_n dx \stackrel{\text{def}}{=} T_{2,1} + T_{2,2}. \end{aligned}$$

146 We observe that $T_{2,1} \leq \epsilon_{\mathcal{D}_n}(\varphi) \|u_n\|_{\mathcal{T}_n}$. Thanks to Proposition 6, $\|u_n\|_{\mathcal{T}_n}$ is uniformly bounded
 147 with respect to n . Thus, according to property (P3), $T_{2,1} \rightarrow 0$ as $n \rightarrow \infty$. The weak convergence
 148 of $\{\tilde{\nabla}_{\mathcal{D}_n} u_n\}_{n \in \mathbb{N}}$ also leads to $T_{2,2} \rightarrow \int_{\Omega} \Lambda \nabla \varphi \cdot \nabla \tilde{u} dx$ as $n \rightarrow \infty$.

149 Let us now consider T_2 . By Proposition 5, $\|\varphi_{\mathcal{T}_n}\|_{\mathcal{T}_n}$ is uniformly bounded with respect to n ;
 150 since $\varphi_{\mathcal{T}_n}$ obviously converges to φ , it is then easy, using Theorem 2, to see that $\tilde{\nabla}_{\mathcal{D}_n} \varphi_{\mathcal{T}_n}$ weakly
 151 converges to $\nabla \varphi$. Proceeding in a similar way as for $a_{\mathcal{T}_n}(u_n, \varphi_{\mathcal{T}_n}, u_n)$, we can thus prove that
 152 $a_{\mathcal{T}_n}(u_n, \varphi_{\mathcal{T}_n}, \varphi_{\mathcal{T}_n}) \rightarrow \int_{\Omega} \Lambda \nabla \varphi \cdot \nabla \varphi dx$ as $n \rightarrow \infty$. Therefore,

$$T_2 \rightarrow \int_{\Omega} \Lambda \nabla \varphi \cdot \nabla (\varphi - \tilde{u}) dx \text{ as } n \rightarrow \infty. \quad (18)$$

153 Using the weak convergence of $\tilde{\nabla}_{\mathcal{D}_n}(u_n - \varphi_{\mathcal{T}_n})$ in $[L^2(\Omega)]^d$, we get that $\liminf_{n \rightarrow \infty} \|\tilde{\nabla}_{\mathcal{D}_n}(u_n - \varphi_{\mathcal{T}_n})\|_{[L^2(\Omega)]^d} \geq$
 154 $\|\nabla(\tilde{u} - \varphi)\|_{[L^2(\Omega)]^d}$.

155 Plugging (17) and (18) into the right hand side of (16), we conclude that, for all $\varphi \in \mathfrak{D}$,

$$\|\nabla(\tilde{u} - \varphi)\|_{[L^2(\Omega)]^d}^2 \leq \frac{d}{\gamma_1} \left(\int_{\Omega} f(\tilde{u} - \varphi) dx + \int_{\Omega} \Lambda \nabla \varphi \cdot \nabla (\varphi - \tilde{u}) dx \right).$$

156 Thanks to the definition of the test space, we can apply this inequality to a sequence $\{\varphi_m\}_{m \in \mathbb{N}} \in \mathfrak{D}$
 157 which tends to $\bar{u}$ in $H_0^1(\Omega)$ and let $m \rightarrow \infty$; since $\bar{u}$ solves problem (1), we obtain

$$\|\nabla(\tilde{u} - \bar{u})\|_{[L^2(\Omega)]^d}^2 \leq \frac{d}{\gamma_1} \left[\int_{\Omega} f(\tilde{u} - \bar{u}) dx - \int_{\Omega} \Lambda \nabla \bar{u} \cdot \nabla (\tilde{u} - \bar{u}) dx \right] = 0,$$

158 i.e., $\tilde{u} = \bar{u}$. Due to the uniqueness of the solution of (1), we deduce that the entire sequence
 159 $\{u_n\}_{n \in \mathbb{N}}$ converges to $\bar{u}$ in $L^q(\Omega)$ for all $q \in [1, 2d/(d-2))$ (and weakly in $L^{2d/(d-2)}(\Omega)$ if $d > 2$).
 160 Note that the order in which the limits for $n \rightarrow \infty$ and $m \rightarrow \infty$ are taken cannot be exchanged,
 161 since the sequence $\{ \|(\varphi_m)_{\mathcal{T}_n}\|_{\mathcal{T}_n, I} \}_{m \in \mathbb{N}}$ is possibly unbounded. This concludes the proof. $\square$

2.3. Existence of a discrete solution

In this section, we briefly discuss the existence of discrete solutions for problem (4). Thanks to Proposition 6, Remark 3 and the application of Brouwer's topological degree leads to the proposition below whose proof is omitted here (see Proposition 3.4 in [19, 23] for more details).

Proposition 1 (Existence of a discrete solution). *Assume that property (P2) of Hypotheses 1 holds and that for each $n \in \mathbb{N}$, $\mathbb{A}_{\mathcal{T}_n}$ is continuous on $H_{\mathcal{T}_n}(\Omega)$. Then, problem (4) admits at least one solution $u_n \in H_{\mathcal{T}_n}(\Omega)$ for each $n \in \mathbb{N}$.*

3. Application to some nonlinear finite volume schemes

An established idea to obtain monotone or extremum-principles-preserving schemes, as those developed in [15, 16, 17, 18, 20, 21, 24, 19], is to compute for each interior edge $\sigma \in \mathcal{E}_{\text{int}}$, with $\mathcal{T}_\sigma = \{K, L\}$, two consistent linear flux approximations $\tilde{F}_{K,\sigma}(u)$ and $\tilde{F}_{L,\sigma}(u)$ depending on the unknown $u \in H_{\mathcal{T}}(\Omega)$, and to define the final flux $F_{K,\sigma}(u, u)$ as a convex combination of these fluxes with coefficients also depending on u :

$$F_{K,\sigma}(u, u) = \mu_{K,\sigma}(u) \tilde{F}_{K,\sigma}(u) - \mu_{L,\sigma}(u) \tilde{F}_{L,\sigma}(u), \quad (19)$$

with $\mu_{K,\sigma}(u) \geq 0, \mu_{L,\sigma}(u) \geq 0$ and $\mu_{K,\sigma}(u) + \mu_{L,\sigma}(u) = 1$.

For any $K \in \mathcal{T}$ and $\sigma \in \mathcal{E}_K \cap \mathcal{E}_{\text{int}}$, the linear flux $\tilde{F}_{K,\sigma}(u)$ is built in order to ensure the strong consistency, i.e, there exist $\mathfrak{D} \subset C_0(\overline{\Omega})$, a dense subspace of $H_0^1(\Omega)$, and $0 < C_1 < +\infty$ depending only on the mesh regularity (2), s.t. for all $\varphi \in \mathfrak{D}$,

$$\forall K \in \mathcal{T}, \forall \sigma \in \mathcal{E}_K, \quad \left| \tilde{F}_{K,\sigma}(\varphi_{\mathcal{T}}) - m_\sigma \langle \Lambda \nabla \varphi \rangle_K \cdot \mathbf{n}_{K,\sigma} \right| \leq C_1 m_\sigma h_{\mathcal{D}}. \quad (20)$$

In (41) and (42) of Section 4, we specify the choice of the space $\mathfrak{D}$ related to the strong consistency property (20).

The coefficients $\mu_{K,\sigma}(u)$ and $\mu_{L,\sigma}(u)$ are chosen to eliminate the "bad" parts of $\tilde{F}_{K,\sigma}(u)$ and $\tilde{F}_{L,\sigma}(u)$, that are responsible for the possible loss of monotonicity. For any $K \in \mathcal{T}$, $\sigma \in \mathcal{E}_K \cap \mathcal{E}_{\text{int}}$ and $L \in \mathcal{T}_K$ such that $\mathcal{T}_\sigma = \{K, L\}$, we thus get from (19) the function $F_{K,\sigma}(\cdot, \cdot)$, defined for all $(u, v) \in [H_{\mathcal{T}}(\Omega)]^2$, as

$$F_{K,\sigma}(u, v) = \mu_{K,\sigma}(u) \tilde{F}_{K,\sigma}(v) - \mu_{L,\sigma}(u) \tilde{F}_{L,\sigma}(v). \quad (21)$$

It is observed that for any $\sigma \in \mathcal{E}_{\text{int}}$ with $\mathcal{T}_\sigma = \{K, L\}$, the fluxes are conservative, i.e, $F_{K,\sigma}(u, v) + F_{L,\sigma}(u, v) = 0$. Thus, from Section 2, the finite volume scheme (5) defined from the fluxes (19) is equivalent to problem (4) with the form $a_{\mathcal{T}}$ (8), which is defined from the fluxes (21). Therefore, the following corollary can be deduced.

188 **Corollary 1.** *Let $\{\mathcal{D}_n\}_{n \in \mathbb{N}}$ be an admissible family of discretizations matching Definition 1 s.t.*
 189 *$h_{\mathcal{D}_n} \rightarrow 0$ as $n \rightarrow \infty$. We have the following results:*

- 190 • *if, for all $n \in \mathbb{N}$, $K \in \mathcal{T}_n$ and $\sigma \in \mathcal{E}_K$, the functions $v \mapsto F_{K,\sigma}(v, v)$, defined by (19), are*
 191 *continuous on $H_{\mathcal{T}_n}(\Omega)$ and if the uniform coercivity property (P2) holds, then there exists at*
 192 *least one solution $u_n \in H_{\mathcal{T}_n}(\Omega)$ of problem (5);*
- 193 • *if, in addition, the strong consistency property (20) is satisfied, then the sequence $\{u_n\}_{n \in \mathbb{N}}$*
 194 *of discrete solutions of problem (5), with numerical fluxes defined by (19), converges to the*
 195 *solution $\bar{u}$ of the continuous problem (1) in $L^q(\Omega)$ for all $q \in [1, 2d/(d-2))$ (and weakly in*
 196 *$L^{2d/(d-2)}(\Omega)$ if $d > 2$) as $n \rightarrow \infty$.*

197 *Proof.* To prove this result, we use the equivalence between the problem (5) and (4) with $a_{\mathcal{T}_n}$
 198 defined by (8). By assumption, we get that for any $n \in \mathbb{N}$ and for all $K \in \mathcal{T}_n$ and $\sigma \in \mathcal{E}_K$, the
 199 function $v \mapsto F_{K,\sigma}(v, v)$ is continuous. From (8) and (9), we notice that the function $\mathbb{A}_{\mathcal{T}_n}$, defined
 200 here by $(\mathbb{A}_{\mathcal{T}_n}(v))_K = -\sum_{\sigma \in \mathcal{E}_K} F_{K,\sigma}(v, v)$ for all $K \in \mathcal{T}_n$, is continuous on $H_{\mathcal{T}_n}(\Omega)$. Therefore,
 201 thanks to Proposition 1, we infer that for each $n \in \mathbb{N}$, there exists at least one solution $u_n \in H_{\mathcal{T}_n}(\Omega)$
 202 to the problem (5), which gives the first result. The second one is a consequence of Theorem 1
 203 since

- 204 • the fluxes $\{\tilde{F}_{K,\sigma}(\cdot)\}_{K \in \mathcal{T}_n, \sigma \in \mathcal{E}_K}$ are linear on $H_{\mathcal{T}_n}(\Omega)$, which gives (P1),
- 205 • the consistency of the fluxes (P3) can be obtained by proving the strong consistency of the
 206 fluxes $F_{K,\sigma}$ given by (21) (see Remark 4 which holds by assumption (20).

207 □

208 4. Construction of nonlinear finite volume schemes

209 In the previous section, the proof of the convergence of nonlinear finite volume schemes of type
 210 (19) has been given. In this section, we describe two schemes existing in the literature with some
 211 improvements, where the first scheme is monotone (see [15, 16, 17, 18, 21]) and the second one
 212 satisfies discrete extremum principles (see [19, 24, 25, 20]). Please note that for nonlinear schemes
 213 monotonicity only guarantees that the scheme is positivity-preserving. The presented schemes
 214 differ in the choice of the weights $\mu_{K,\sigma}, \mu_{L,\sigma}$ (19).

215 4.1. Consistent flux approximations

216 In the following, the fluxes $\tilde{F}_{K,\sigma}(u), \tilde{F}_{L,\sigma}(u)$ are constructed such that (20) holds. The decom-
 217 position of the conormal, defined as $\langle \Lambda \rangle_K \mathbf{n}_{K,\sigma}$, in a basis $(\mathbf{x}_{\sigma'} - \mathbf{x}_K)_{\{\sigma' \in \mathcal{S}_{K,\sigma}\}}$ with coordinates
 218 $(\alpha_{K,\sigma\sigma'})_{\{\sigma' \in \mathcal{S}_{K,\sigma}\}}$ with $\mathcal{S}_{K,\sigma} \subset \mathcal{E}_K$ is calculated by solving the following optimization problem

$$\min_{\gamma \geq 0, \tilde{\alpha} \in \mathbb{R}^{|\mathcal{E}_K|}} \kappa\gamma + \sum_{\sigma' \in \mathcal{E}_K} \tilde{\alpha}_{\sigma'} \quad \text{subject to} \quad \frac{\langle \Lambda \rangle_K \mathbf{n}_{K,\sigma}}{|\langle \Lambda \rangle_K \mathbf{n}_{K,\sigma}|} = \sum_{\sigma' \in \mathcal{E}_K} \tilde{\alpha}_{\sigma'} \frac{\mathbf{x}_{\sigma'} - \mathbf{x}_K}{|\mathbf{x}_{\sigma'} - \mathbf{x}_K|} \quad (22)$$

$$\sum_{\sigma' \in \mathcal{E}_K} \tilde{\alpha}_{\sigma'} \frac{|\langle \Lambda \rangle_K \mathbf{n}_{K,\sigma}|}{|\mathbf{x}_{\sigma'} - \mathbf{x}_K|} \geq \delta, \quad -C_\alpha \leq -\gamma \leq \tilde{\alpha}_{\sigma'} \leq C_\alpha,$$

for given strictly positive parameters δ and C_α . Specifying the final coefficients as

$$\alpha_{K,\sigma\sigma'} \stackrel{\text{def}}{=} \tilde{\alpha}_{\sigma'} \frac{|\langle \Lambda \rangle_K \mathbf{n}_{K,\sigma}|}{|\mathbf{x}_{\sigma'} - \mathbf{x}_K|}, \quad (23)$$

results in the following conormal decomposition

$$\langle \Lambda \rangle_K \mathbf{n}_{K,\sigma} = \sum_{\sigma' \in \mathcal{S}_{K,\sigma}} \alpha_{K,\sigma\sigma'} (\mathbf{x}_{\sigma'} - \mathbf{x}_K), \quad (24)$$

where the face stencil is defined as

$$\mathcal{S}_{K,\sigma} \stackrel{\text{def}}{=} \{\sigma' \in \mathcal{E}_K \mid \alpha_{K,\sigma\sigma'} \neq 0\}. \quad (25)$$

This decomposition is used to define consistent flux approximations $\tilde{F}_{K,\sigma}(u), \tilde{F}_{L,\sigma}(u)$. The idea of formulating the conormal decomposition as an optimization problem has been recently introduced in [26].

Proposition 2. *Let $\mathcal{D}$ be an element of a family of discretizations matching Definition 1 and let $\alpha_{K,\sigma\sigma'}$ be calculated from (22)-(23). Then, for any $\varphi \in C^2(\mathcal{T}) \cap C_0(\bar{\Omega})$ and $K \in \mathcal{T}$, we have the following estimate:*

$$\left| \mathbf{m}_\sigma \langle \Lambda \nabla \varphi \rangle_K \cdot \mathbf{n}_{K,\sigma} - \mathbf{m}_\sigma \sum_{\sigma' \in \mathcal{S}_{K,\sigma}} \alpha_{K,\sigma\sigma'} (\varphi(\mathbf{x}_{\sigma'}) - \varphi(\mathbf{x}_K)) \right| \leq C \mathbf{m}_\sigma \text{diam}(K). \quad (26)$$

Proof. We observe that for any $\varphi \in C^2(\mathcal{T}) \cap C_0(\bar{\Omega})$ and $K \in \mathcal{T}$,

$$\begin{aligned} \mathbf{m}_\sigma \langle \Lambda \nabla \varphi \rangle_K \cdot \mathbf{n}_{K,\sigma} &= \frac{\mathbf{m}_\sigma}{\mathbf{m}_K} \int_K \Lambda \nabla \varphi \cdot \mathbf{n}_{K,\sigma} \, dx \\ &= \frac{\mathbf{m}_\sigma}{\mathbf{m}_K} \int_K \Lambda(x) (\nabla \varphi(x) - \nabla \varphi(\mathbf{x}_K)) \cdot \mathbf{n}_{K,\sigma} \, dx + \mathbf{m}_\sigma \langle \Lambda \rangle_K \nabla \varphi(\mathbf{x}_K) \cdot \mathbf{n}_{K,\sigma}. \end{aligned} \quad (27)$$

Since K is star-shaped with respect to $\mathbf{x}_K$ Taylor's Theorem can be used to infer

$$\left| \frac{\mathbf{m}_\sigma}{\mathbf{m}_K} \int_K \Lambda(x) (\nabla \varphi(x) - \nabla \varphi(\mathbf{x}_K)) \cdot \mathbf{n}_{K,\sigma} \, dx \right| \leq C_\varphi \beta_0 \mathbf{m}_\sigma \text{diam}(K), \quad (28)$$

where $C_\varphi = \mathcal{O}(\|\varphi\|_{C^2(K)})$.

Let us now estimate the second term in the right hand side of equation (27). Inserting the conormal decomposition (24) yields

$$\mathbf{m}_\sigma \nabla \varphi(\mathbf{x}_K) \cdot \langle \Lambda \rangle_K \mathbf{n}_{K,\sigma} = \mathbf{m}_\sigma \sum_{\sigma' \in \mathcal{S}_{K,\sigma}} \alpha_{K,\sigma\sigma'} \nabla \varphi(\mathbf{x}_K) \cdot (\mathbf{x}_{\sigma'} - \mathbf{x}_K). \quad (29)$$

Since K is star-shaped with respect to $\mathbf{x}_K$, Taylor's Theorem can again be used to deduce that for all $\sigma' \in \mathcal{S}_{K,\sigma}$,

$$|\varphi(\mathbf{x}_{\sigma'}) - \varphi(\mathbf{x}_K) - \nabla\varphi(\mathbf{x}_K) \cdot (\mathbf{x}_{\sigma'} - \mathbf{x}_K)| \leq C_\varphi \text{diam}(K)^2. \quad (30)$$

Owing to (29) and (30), we get

$$\left| \mathbf{m}_\sigma \nabla\varphi(\mathbf{x}_K) \cdot \langle \Lambda \rangle_K \mathbf{n}_{K,\sigma} - \mathbf{m}_\sigma \sum_{\sigma' \in \mathcal{S}_{K,\sigma}} \alpha_{K,\sigma\sigma'} (\varphi(\mathbf{x}_{\sigma'}) - \varphi(\mathbf{x}_K)) \right| \leq \mathbf{m}_\sigma C_\varphi \text{diam}(K)^2 \sum_{\sigma' \in \mathcal{S}_{K,\sigma}} |\alpha_{K,\sigma\sigma'}|. \quad (31)$$

Due to the constraints of the optimization problem (22), we observe that for all $\sigma' \in \mathcal{S}_{K,\sigma}$,

$$|\alpha_{K,\sigma\sigma'}| \leq C_\alpha \frac{|\langle \Lambda \rangle_K \mathbf{n}_{K,\sigma}|}{|\mathbf{x}_{\sigma'} - \mathbf{x}_K|}. \quad (32)$$

We thus deduce from (2) that for all $\sigma' \in \mathcal{S}_{K,\sigma}$,

$$|\alpha_{K,\sigma\sigma'}| \leq \frac{C_\alpha \beta_0}{\varrho_1 \text{diam}(K)}. \quad (33)$$

Using (31) and (33), it follows that

$$\left| \mathbf{m}_\sigma \nabla\varphi(\mathbf{x}_K) \cdot \langle \Lambda \rangle_K \mathbf{n}_{K,\sigma} - \mathbf{m}_\sigma \sum_{\sigma' \in \mathcal{S}_{K,\sigma}} \alpha_{K,\sigma\sigma'} (\varphi(\mathbf{x}_{\sigma'}) - \varphi(\mathbf{x}_K)) \right| \leq |\mathcal{E}_K| \mathbf{m}_\sigma C_\varphi C_\alpha \frac{\beta_0}{\varrho_1} \text{diam}(K). \quad (34)$$

Then, including (28) and (34) the following desired estimate is obtained from (27)

$$\left| \mathbf{m}_\sigma \langle \Lambda \nabla \varphi \rangle_K \cdot \mathbf{n}_{K,\sigma} - \mathbf{m}_\sigma \sum_{\sigma' \in \mathcal{S}_{K,\sigma}} \alpha_{K,\sigma\sigma'} (\varphi(\mathbf{x}_{\sigma'}) - \varphi(\mathbf{x}_K)) \right| \leq C_\varphi \beta_0 \left(1 + \frac{C_\alpha |\mathcal{E}_K|}{\varrho_1} \right) \mathbf{m}_\sigma \text{diam}(K), \quad (35)$$

which completes the proof. $\square$

Corollary 2 (Strong consistency). *Let $\mathcal{D}$ be an element of a family of discretizations matching Definition 1. Let $\alpha_{K,\sigma\sigma'}$ be calculated from (22)-(23). Let $\mathfrak{D}$ be a dense subspace of $H_0^1(\Omega)$ s.t. $\mathfrak{D} \subset C^2(\mathcal{T}) \cap C_0(\overline{\Omega})$. For $\sigma \in \mathcal{E}$, let $I_\sigma \in \mathcal{L}(H_{\mathcal{T}}(\Omega); \mathbb{P}^0(\sigma))$, be a trace reconstruction operator such that for all $\varphi \in \mathfrak{D}$*

$$|I_\sigma \varphi_{\mathcal{T}} - \varphi(\mathbf{x}_\sigma)| \leq \varrho h_{\mathcal{D}}^2, \quad (36)$$

where $\varrho > 0$ only depends on the mesh regularities (2). Then, the linear fluxes defined as

$$\tilde{F}_{K,\sigma}(v) \stackrel{\text{def}}{=} \mathbf{m}_\sigma \sum_{\sigma' \in \mathcal{S}_{K,\sigma}} \alpha_{K,\sigma\sigma'} (I_{\sigma'} v - v_K), \quad \forall v \in H_{\mathcal{T}}(\Omega), K \in \mathcal{T}, \sigma \in \mathcal{E}_K, \quad (37)$$

satisfy the strong consistency assumption (20).

Proof. Thanks to Proposition 2, we obtain that for all $\varphi \in \mathfrak{D}$

$$\begin{aligned} \left| \mathbf{m}_\sigma \langle \Lambda \nabla \varphi \rangle_K \cdot \mathbf{n}_{K,\sigma} - \tilde{F}_{K,\sigma}(\varphi_{\mathcal{T}}) \right| &\leq C \mathbf{m}_\sigma \text{diam}(K) \\ &+ \mathbf{m}_\sigma \max_{\sigma' \in \mathcal{S}_{K,\sigma}} |I_{\sigma'} \varphi_{\mathcal{T}} - \varphi(\mathbf{x}_{\sigma'})| \sum_{\sigma' \in \mathcal{S}_{K,\sigma}} |\alpha_{K,\sigma\sigma'}|. \end{aligned} \quad (38)$$

248 However, thanks to (33), we have $\sum_{\sigma' \in \mathcal{S}_{K,\sigma}} |\alpha_{K,\sigma\sigma'}| \leq \frac{C_\alpha |\mathcal{E}_K| \beta_0}{\varrho_1 \text{diam}(K)}$ and then from (38) we deduce
 249 that

$$\begin{aligned} \left| m_\sigma \langle \Lambda \nabla \varphi \rangle_{K \cdot \mathbf{n}_{K,\sigma}} - \tilde{F}_{K,\sigma}(\varphi_{\mathcal{T}}) \right| &\leq C m_\sigma \text{diam}(K) \\ &+ \frac{C_\alpha |\mathcal{E}_K| \beta_0}{\varrho_1} \frac{m_\sigma}{\text{diam}(K)} \max_{\sigma' \in \mathcal{S}_{K,\sigma}} |I_{\sigma'} \varphi_{\mathcal{T}} - \varphi(\mathbf{x}_{\sigma'})|. \end{aligned} \quad (39)$$

250 On one hand, for any $K \in \mathcal{T}$, we have $\text{diam}(K) \leq h_{\mathcal{D}}$. On the other hand, thanks to (2), for any
 251 $K \in \mathcal{T}$, we get $\frac{1}{\text{diam}(K)} \leq \frac{1}{\varrho_3 h_{\mathcal{D}}}$. Therefore from (39), we infer

$$\begin{aligned} \left| m_\sigma \langle \Lambda \nabla \varphi \rangle_{K \cdot \mathbf{n}_{K,\sigma}} - \tilde{F}_{K,\sigma}(\varphi_{\mathcal{T}}) \right| &\leq C m_\sigma h_{\mathcal{D}} \\ &+ \frac{C_\alpha |\mathcal{E}_K| \beta_0}{\varrho_1 \varrho_3} \frac{m_\sigma}{h_{\mathcal{D}}} \max_{\sigma' \in \mathcal{S}_{K,\sigma}} |I_{\sigma'} \varphi_{\mathcal{T}} - \varphi(\mathbf{x}_{\sigma'})|. \end{aligned} \quad (40)$$

252 The strong consistency of the fluxes follows due to assumption (36). $\square$

253 4.2. Choice of trace reconstruction operators

254 With the result obtained in the last section, we now propose choices for the space $\mathfrak{D}$ and the
 255 trace reconstruction operators $I_\sigma \in \mathcal{L}(H_{\mathcal{T}}(\Omega); \mathbb{P}^0(\sigma))$. The first choice consists in taking for all
 256 $u \in H_{\mathcal{T}}(\Omega)$, $\sigma \in \mathcal{E}_{\text{int}}$:

$$\begin{aligned} \mathfrak{D} &= C_c^\infty(\Omega), \\ I_\sigma u &= \sum_{K \in \mathcal{B}_\sigma} \beta_{K,\sigma} u_K, \end{aligned} \quad (41)$$

257 where $\mathcal{B}_\sigma$ is a subset of $\mathcal{T}$ with $\text{card}(\mathcal{B}_\sigma) \geq d$, and $(\beta_{K,\sigma})_{K \in \mathcal{B}_\sigma}$ is a family of nonnegative real
 258 numbers such that $\sum_{K \in \mathcal{B}_\sigma} \beta_{K,\sigma} = 1$ and $\mathbf{x}_\sigma = \sum_{K \in \mathcal{B}_\sigma} \beta_{K,\sigma} \mathbf{x}_K$. Both choices in (41) ensure that
 259 Corollary 1 is satisfied for the nonlinear finite volume schemes considered in Section 3 with the
 260 assumption that the permeability Λ belongs to $L^\infty(\Omega)$. Our result is thus an improvement of the
 261 convergence result obtained in [19] which requires Λ to be piecewise Lipschitz-continuous on Ω .

262

263 However, the choice of a convex combination made in (41), and in [19] as well, does not allow
 264 us to retrieve exactly piecewise linear solutions of problem (1) for heterogeneous permeabilities Λ
 265 which are cell-wise C^2 on Ω . This choice may lead to non-physical solutions of problem (1) for
 266 this kind of permeability functions. To handle these cases, we propose a second choice for $\mathfrak{D}$ and
 267 the trace reconstruction operators. To that purpose, we make the following hypotheses.

268 **Hypotheses 2.** (Q1) $P_\Omega \stackrel{\text{def}}{=} \{\Omega_i\}_{i=1 \dots N_\Omega}$ is a finite partition of Ω into open connected disjoint
 269 polygonal subsets,

270 (Q2) Λ is a symmetric tensor-valued function such that $\Lambda|_{\Omega_i} \in [C^2(\overline{\Omega_i})]^{d \times d}$ for all $i = 1 \dots N_\Omega$,

271 (Q3) $\mathcal{T}$ is compatible with P_Ω (each cell is contained in one element of the partition P_Ω).

272 We then suggest, with these additional assumptions, to take, for all $u \in H_T(\Omega)$, $\sigma \in \mathcal{E}_{\text{int}}$:

$$\begin{aligned} \mathfrak{D} &= \mathcal{Q}, \\ I_\sigma u &= \omega_K u_K + \omega_L u_L, \end{aligned} \quad (42)$$

273 where $\mathcal{Q}$ is defined and proved to be dense in $H_0^1(\Omega)$, as described in Proposition 3, and ω_K and
274 ω_L given below, are the coefficients defining the harmonic averaging interpolator introduced in
275 [27]:

$$\begin{aligned} \omega_K &= \frac{d_{L,\sigma} \tau_{K,\sigma}}{d_{L,\sigma} \tau_{K,\sigma} + d_{K,\sigma} \tau_{L,\sigma}}, \quad \omega_L = \frac{d_{K,\sigma} \tau_{L,\sigma}}{d_{L,\sigma} \tau_{K,\sigma} + d_{K,\sigma} \tau_{L,\sigma}}, \\ \tau_{K,\sigma} &= \mathbf{n}_{K,\sigma} \langle \Lambda \rangle_K \mathbf{n}_{K,\sigma}, \quad \tau_{L,\sigma} = \mathbf{n}_{L,\sigma} \langle \Lambda \rangle_L \mathbf{n}_{L,\sigma}, \\ \mathbf{x}_\sigma &= \omega_K \mathbf{x}_K + \omega_L \mathbf{x}_L + \frac{d_{K,\sigma} d_{L,\sigma}}{d_{L,\sigma} \tau_{K,\sigma} + d_{K,\sigma} \tau_{L,\sigma}} (\langle \Lambda \rangle_K - \langle \Lambda \rangle_L) \mathbf{n}_{K,\sigma}. \end{aligned}$$

276 With the same ideas as the ones used for the proof of Lemma 7 in [4] and the additional Hypotheses
277 2, the property (36) is satisfied with the choices (42).

278 The previous strategies can be generalized with the following reconstruction operator

$$I_\sigma u = \sum_{M \in \mathcal{I}_\sigma} \omega_{M,\sigma} u_M, \quad \sum_{M \in \mathcal{I}_\sigma} \omega_{M,\sigma} = 1, \quad \omega_{M,\sigma} \geq 0, \quad (43)$$

279 with interpolation index set $\mathcal{I}_\sigma$. It is assumed that $\omega_{M,\sigma} = 0$ if $M \notin \mathcal{I}_\sigma$. In the next sections,
280 two nonlinear schemes are derived by using the consistent flux approximations (37) with trace
281 reconstruction operators (43).

282 4.3. Nonlinear Two-Point Flux Approximation

283 In this section, a nonlinear two-point flux approximation (NLTPFA) is derived, using concepts
284 presented in [16, 17, 18, 21]. Inserting (37) into (21), using the reconstruction operator (43),
285 reordering the terms and using the fact that $\sum_{M \in \mathcal{I}_\sigma} \omega_M = 1$ yield:

$$F_{K,\sigma}(u, v) = t_{L,\sigma}(u) v_L - t_{K,\sigma}(u) v_K - \underbrace{(\mu_{L,\sigma}(u) \lambda_{L,\sigma}(v) - \mu_{K,\sigma}(u) \lambda_{K,\sigma}(v))}_{\stackrel{\text{def}}{=} R_{K,\sigma}(u, v)}, \quad (44)$$

286 with the transmissibilities

$$\begin{aligned} t_{K,\sigma}(u) &= m_\sigma \left(\mu_{K,\sigma}(u) \sum_{\sigma' \in \mathcal{S}_{K,\sigma}} \sum_{M \in \{\mathcal{I}_{\sigma'} \setminus \{K\}\}} \alpha_{K,\sigma\sigma'} \omega_{M,\sigma'} + \mu_{L,\sigma}(u) \sum_{\sigma' \in \mathcal{S}_{L,\sigma}} \sum_{M \in \{\mathcal{I}_{\sigma'} \cap \{K\}\}} \alpha_{L,\sigma\sigma'} \omega_{M,\sigma'} \right), \\ t_{L,\sigma}(u) &= m_\sigma \left(\mu_{L,\sigma}(u) \sum_{\sigma' \in \mathcal{S}_{L,\sigma}} \sum_{M \in \{\mathcal{I}_{\sigma'} \setminus \{L\}\}} \alpha_{L,\sigma\sigma'} \omega_{M,\sigma'} + \mu_{K,\sigma}(u) \sum_{\sigma' \in \mathcal{S}_{K,\sigma}} \sum_{M \in \{\mathcal{I}_{\sigma'} \cap \{L\}\}} \alpha_{K,\sigma\sigma'} \omega_{M,\sigma'} \right), \end{aligned} \quad (45)$$

287 and

$$\begin{aligned} \lambda_{K,\sigma}(v) &\stackrel{\text{def}}{=} m_\sigma \sum_{\sigma' \in \mathcal{S}_{K,\sigma}} \sum_{M \in \{\mathcal{I}_{\sigma'} \setminus \{K,L\}\}} \alpha_{K,\sigma\sigma'} \omega_{M,\sigma'} v_M, \\ \lambda_{L,\sigma}(v) &\stackrel{\text{def}}{=} m_\sigma \sum_{\sigma' \in \mathcal{S}_{L,\sigma}} \sum_{M \in \{\mathcal{I}_{\sigma'} \setminus \{K,L\}\}} \alpha_{L,\sigma\sigma'} \omega_{M,\sigma'} v_M. \end{aligned} \quad (46)$$

288 In order to obtain a nonlinear two-point flux approximation, the following weights are considered:

289

$$\begin{aligned} \mu_{K,\sigma}(u) &= 0.5, \quad \mu_{L,\sigma}(u) = 0.5, \quad \text{if } \lambda_{L,\sigma}(u) = \lambda_{K,\sigma}(u) = 0, \\ \mu_{K,\sigma}(u) &= \frac{|\lambda_{L,\sigma}(u)|}{|\lambda_{K,\sigma}(u)| + |\lambda_{L,\sigma}(u)|}, \quad \mu_{L,\sigma}(u) = \frac{|\lambda_{K,\sigma}(u)|}{|\lambda_{K,\sigma}(u)| + |\lambda_{L,\sigma}(u)|}, \quad \text{otherwise.} \end{aligned} \quad (47)$$

290 Therefore, from (44), the flux $F_{K,\sigma}(u, u)$ reads:

$$F_{K,\sigma}(u, u) = t_{L,\sigma}(u)u_L - t_{K,\sigma}(u)u_K - R_{K,\sigma}(u, u). \quad (48)$$

291 Under the assumption that $\lambda_{L,\sigma}(u)\lambda_{K,\sigma}(u) \geq 0$, it is inferred from (48) that:

$$F_{K,\sigma}(u, u) = t_{L,\sigma}(u)u_L - t_{K,\sigma}(u)u_K. \quad (49)$$

292 By virtue of (49), we thus get a nonlinear two-point flux approximation. However, to get the
293 convergence of the finite volume scheme defined by the fluxes (48) using Corollary 1, the function
294 $u \mapsto F_{K,\sigma}(u, u)$ must be continuous, which is not a priori the case. The problem comes from the
295 definition (47) of the function $u \mapsto \mu_{K,\sigma}(u)$ for which discontinuities can appear. Thus, in order
296 to guarantee the continuity of the function $u \mapsto F_{K,\sigma}(u, u)$, we finally choose the weights as:

$$\mu_{K,\sigma}(u) = \frac{|\lambda_{L,\sigma}(u)| + \epsilon}{|\lambda_{K,\sigma}(u)| + |\lambda_{L,\sigma}(u)| + 2\epsilon}, \quad \mu_{L,\sigma}(u) = \frac{|\lambda_{K,\sigma}(u)| + \epsilon}{|\lambda_{K,\sigma}(u)| + |\lambda_{L,\sigma}(u)| + 2\epsilon}, \quad (50)$$

297 with $\epsilon > 0$ such that $0 < \epsilon \leq h_{\mathcal{D}} \min_{\sigma \in \mathcal{E}} m_{\sigma}$. Thus, the convergence of the finite volume scheme
298 defined by the fluxes (48) with weights (50) is obtained thanks to Corollary 1.

299 Let us now discuss the monotonicity of the finite volume scheme defined by the fluxes (48).
300 First, we observe that, under some conditions, we can rewrite the flux $F_{K,\sigma}(u, u)$ given by the
301 expression (48) to obtain a nonlinear two-point flux approximation. Indeed,

302 • if we have

$$R_{K,\sigma}(u, u) = 0, \quad (51)$$

303 then the flux $F_{K,\sigma}(u, u)$ given by (48) becomes:

$$F_{K,\sigma}(u, u) = t_{L,\sigma}(u)u_L - t_{K,\sigma}(u)u_K;$$

304 • if we have

$$R_{K,\sigma}(u, u) > 0 \text{ and } u_K \neq 0, \quad (52)$$

305 then the flux $F_{K,\sigma}(u, u)$ given by (48) can be rewritten as:

$$F_{K,\sigma}(u, u) = t_{L,\sigma}(u)u_L - \left(t_{K,\sigma}(u) + \frac{R_{K,\sigma}(u, u)}{u_K} \right) u_K.$$

306 • if we have

$$R_{K,\sigma}(u, u) < 0 \text{ and } u_L \neq 0, \quad (53)$$

307 then the flux $F_{K,\sigma}(u, u)$ given by (48) can be rewritten as:

$$F_{K,\sigma}(u, u) = \left(t_{L,\sigma}(u) - \frac{R_{K,\sigma}(u, u)}{u_L} \right) u_L - t_{K,\sigma}(u) u_K.$$

308 Furthermore, under the assumption that

$$\lambda_{L,\sigma}(u) \lambda_{K,\sigma}(u) \geq 0, \quad (54)$$

309 the flux $F_{K,\sigma}(u, u)$ defined by (48) with weights (50) can be rewritten as:

$$F_{K,\sigma}(u, u) = t_{L,\sigma}(u) u_L - t_{K,\sigma}(u) u_K - \underbrace{\epsilon \frac{\lambda_{L,\sigma}(u) - \lambda_{K,\sigma}(u)}{|\lambda_{K,\sigma}(u)| + |\lambda_{L,\sigma}(u)| + 2\epsilon}}_{\stackrel{\text{def}}{=} \mathfrak{E}_{K,\sigma}(u)}, \quad (55)$$

310 where we observe that

$$|\mathfrak{E}_{K,\sigma}(u)| \leq \epsilon. \quad (56)$$

311 Thus, thanks to Equation (55) and inequality (56), it is inferred that under the assumption that
 312 $\lambda_{L,\sigma}(u) \lambda_{K,\sigma}(u) \geq 0$, the flux $F_{K,\sigma}(u, u)$ defined by (48) with weights (50) is close to a nonlinear
 313 two-point flux approximation provided that ϵ is sufficiently small.

314 Thus, for the monotonicity property of the scheme, we get the following result:

315 Provided that for all $\sigma \in \mathcal{E}_{\text{int}}$ with $\mathcal{T}_\sigma = \{K, L\}$, one of these four conditions (51),(52),(53) or (54)
 316 holds, and the values u_K as well as the α_K and ω_K coefficients are nonnegative, then the resulting
 317 discretization matrix is an M-matrix (for sufficiently small ϵ for the case that the condition (54)
 318 is used).

319 If in addition to that, the source term f is nonnegative, the positivity-preservation of the scheme
 320 using a Picard method can be proven (see [17]).

321

322 4.4. Nonlinear Multi-Point Flux Approximation

323 In this section, we mainly follow ideas presented in [19, 24, 25]. For the derivation of a nonlinear
 324 multi-point flux approximation (NLMPFA), the fluxes (37) are split as follows

$$\begin{aligned} \tilde{F}_{K,\sigma}(v) &\stackrel{\text{def}}{=} \tilde{F}_{K,\sigma}^{(1)}(v) + \tilde{F}_{K,\sigma}^{(2)}(v), \\ \tilde{F}_{L,\sigma}(v) &\stackrel{\text{def}}{=} \tilde{F}_{L,\sigma}^{(1)}(v) + \tilde{F}_{L,\sigma}^{(2)}(v), \end{aligned} \quad (57)$$

325 with

$$\begin{aligned} \tilde{F}_{K,\sigma}^{(1)}(v) &= m_\sigma \alpha_{K,\sigma\sigma} \omega_{L,\sigma} (v_L - v_K), \\ \tilde{F}_{L,\sigma}^{(1)}(v) &= m_\sigma \alpha_{L,\sigma\sigma} \omega_{K,\sigma} (v_K - v_L), \\ \tilde{F}_{K,\sigma}^{(2)}(v) &= m_\sigma \alpha_{K,\sigma\sigma} \sum_{M \in \{\mathcal{I}_\sigma \setminus \{L\}\}} \omega_{M,\sigma} (v_M - v_K) + \sum_{\sigma' \in \{\mathcal{S}_{K,\sigma} \setminus \{\sigma\}\}} m_\sigma \alpha_{K,\sigma\sigma'} (I_{\sigma'} v - v_K), \\ \tilde{F}_{L,\sigma}^{(2)}(v) &= m_\sigma \alpha_{L,\sigma\sigma} \sum_{M \in \{\mathcal{I}_\sigma \setminus \{K\}\}} \omega_{M,\sigma} (v_M - v_L) + \sum_{\sigma' \in \{\mathcal{S}_{L,\sigma} \setminus \{\sigma\}\}} m_\sigma \alpha_{L,\sigma\sigma'} (I_{\sigma'} v - v_L). \end{aligned}$$

326 The weights are chosen as

$$\begin{aligned} \mu_{K,\sigma} &= \mu_{L,\sigma} = 0.5, & \text{if } \tilde{F}_{K,\sigma}^{(2)} = \tilde{F}_{L,\sigma}^{(2)} = 0, \\ \mu_{K,\sigma} &= \frac{|\tilde{F}_{L,\sigma}^{(2)}|}{|\tilde{F}_{K,\sigma}^{(2)}| + |\tilde{F}_{L,\sigma}^{(2)}|}, \quad \mu_{L,\sigma} = \frac{|\tilde{F}_{K,\sigma}^{(2)}|}{|\tilde{F}_{K,\sigma}^{(2)}| + |\tilde{F}_{L,\sigma}^{(2)}|}, & \text{otherwise.} \end{aligned} \quad (58)$$

327 This choice results in the final flux approximations

$$\begin{aligned} F_{K,\sigma}(u, u) &= \mu_{K,\sigma}(u) \tilde{F}_{K,\sigma}^{(1)}(u) - \mu_{L,\sigma}(u) \tilde{F}_{L,\sigma}^{(1)}(u) + \mu_{K,\sigma}(u) \left(1 - \text{sign} \left(\tilde{F}_{K,\sigma}^{(2)}(u) \tilde{F}_{L,\sigma}^{(2)}(u) \right)\right) \tilde{F}_{K,\sigma}^{(2)}(u), \\ F_{L,\sigma}(u, u) &= \mu_{L,\sigma}(u) \tilde{F}_{L,\sigma}^{(1)}(u) - \mu_{K,\sigma}(u) \tilde{F}_{K,\sigma}^{(1)}(u) + \mu_{L,\sigma}(u) \left(1 - \text{sign} \left(\tilde{F}_{K,\sigma}^{(2)}(u) \tilde{F}_{L,\sigma}^{(2)}(u) \right)\right) \tilde{F}_{L,\sigma}^{(2)}(u), \end{aligned} \quad (59)$$

328 where the flux conservation $F_{K,\sigma}(u, u) + F_{L,\sigma}(u, u) = 0$ is obtained. Under the assumption of
329 nonnegative coefficients $\omega_{M,\sigma}, \alpha_{K,\sigma\sigma'}$, discrete extremum principles can be proven for this scheme
330 (see for instance [19, 20]).

331 Again, the function $u \mapsto F_{K,\sigma}(u, u)$ defined by (59) is not a priori continuous when $\tilde{F}_{K,\sigma}^{(2)}(u) =$
332 $\tilde{F}_{L,\sigma}^{(2)}(u) = 0$. To guarantee the continuity, a splitting of the factors $\alpha_{K,\sigma\sigma}\omega_{L,\sigma}$ and $\alpha_{L,\sigma\sigma}\omega_{K,\sigma}$ is
333 carried out in the following way

$$\begin{aligned} \alpha_{K,\sigma\sigma}\omega_{L,\sigma} &= \beta_\sigma + (\alpha_{K,\sigma\sigma}\omega_{L,\sigma} - \beta_\sigma), \\ \alpha_{L,\sigma\sigma}\omega_{K,\sigma} &= \beta_\sigma + (\alpha_{L,\sigma\sigma}\omega_{K,\sigma} - \beta_\sigma), \end{aligned}$$

334 with $\beta_\sigma = \min(\alpha_{K,\sigma\sigma}\omega_{L,\sigma}, \alpha_{L,\sigma\sigma}\omega_{K,\sigma})$. Thus, the fluxes $\tilde{F}_{K,\sigma}(u), \tilde{F}_{L,\sigma}(u)$ from (57) are rewritten
335 as follows

$$\begin{aligned} \tilde{F}_{K,\sigma}(v) &\stackrel{\text{def}}{=} \tilde{F}_{K,\sigma}^{(1)}(v) + \tilde{F}_{K,\sigma}^{(2)}(v), \\ \tilde{F}_{L,\sigma}(v) &\stackrel{\text{def}}{=} \tilde{F}_{L,\sigma}^{(1)}(v) + \tilde{F}_{L,\sigma}^{(2)}(v), \end{aligned} \quad (60)$$

336 with

$$\begin{aligned} \tilde{F}_{K,\sigma}^{(1)}(v) &= m_\sigma \beta_\sigma (v_L - v_K), \\ \tilde{F}_{L,\sigma}^{(1)}(v) &= -\tilde{F}_{K,\sigma}^{(1)}(v), \\ \tilde{F}_{K,\sigma}^{(2)}(v) &= m_\sigma (\alpha_{K,\sigma\sigma}\omega_{L,\sigma} - \beta_\sigma)(v_L - v_K) + m_\sigma \alpha_{K,\sigma\sigma} \sum_{M \in \{\mathcal{I}_\sigma \setminus \{L\}\}} \omega_{M,\sigma} (v_M - v_K) \\ &\quad + \sum_{\sigma' \in \{\mathcal{S}_{K,\sigma} \setminus \{\sigma\}\}} m_\sigma \alpha_{K,\sigma\sigma'} (I_{\sigma'} v - v_K), \\ \tilde{F}_{L,\sigma}^{(2)}(v) &= m_\sigma (\alpha_{L,\sigma\sigma}\omega_{K,\sigma} - \beta_\sigma)(v_K - v_L) + m_\sigma \alpha_{L,\sigma\sigma} \sum_{M \in \{\mathcal{I}_\sigma \setminus \{K\}\}} \omega_{M,\sigma} (v_M - v_L) \\ &\quad + \sum_{\sigma' \in \{\mathcal{S}_{L,\sigma} \setminus \{\sigma\}\}} m_\sigma \alpha_{L,\sigma\sigma'} (I_{\sigma'} v - v_L). \end{aligned}$$

337 The weights, $\mu_{K,\sigma}$ and $\mu_{L,\sigma}$, and the fluxes, $F_{K,\sigma}(u, u)$ and $F_{L,\sigma}(u, u)$, are still defined by (58)
338 and (59), respectively. Now, let us consider the case where $\tilde{F}_{K,\sigma}^{(2)}(u) = \tilde{F}_{L,\sigma}^{(2)}(u) = 0$ for which the
339 functions $\mu_{K,\sigma}$ and $\mu_{L,\sigma}$ are not continuous. However, since $\tilde{F}_{L,\sigma}^{(1)}(v) = -\tilde{F}_{K,\sigma}^{(1)}(v)$, the final flux

340 does not depend on these functions. In fact,

$$\begin{aligned}
F_{K,\sigma}(u, u) &= \mu_{K,\sigma}(u) \tilde{F}_{K,\sigma}^{(1)}(u) - \mu_{L,\sigma}(u) \tilde{F}_{L,\sigma}^{(1)}(u) \\
&= (\mu_{K,\sigma}(u) + \mu_{L,\sigma}(u)) \tilde{F}_{K,\sigma}^{(1)}(u) \\
&= \tilde{F}_{K,\sigma}^{(1)}(u),
\end{aligned}$$

341 which means that for all $K \in \mathcal{T}$, $\sigma \in \mathcal{E}_K$, the function $u \mapsto F_{K,\sigma}(u, u)$ is continuous on $H_{\mathcal{T}}(\Omega)$.

342 The above flux splitting only makes sense if the coefficients $\alpha_{K,\sigma\sigma}, \alpha_{L,\sigma\sigma}$ are positive. This is done

343 by adding the constraints

$$\alpha_{K,\sigma\sigma} \geq \delta_\alpha, \quad \alpha_{L,\sigma\sigma} \geq \delta_\alpha, \quad (61)$$

344 to the optimization problem (22). Thus, the convergence of this scheme is obtained thanks to

345 Corollary 1.

346 5. Numerical results

347 In this section, the behavior of the above mentioned nonlinear finite volume schemes is in-
348 vestigated and compared to linear schemes. The NLTPFA scheme is given by equation (48) with
349 weights (50), the NLMPFA scheme by equation (59), (60), the weights (58) and the additional con-
350 straints (61) for the conormal decomposition. The scheme with fluxes (37) and constant weights
351 $\mu_{K,\sigma} = \mu_{L,\sigma} = 0.5$, which results in a linear scheme, is denoted as AvgMPFA. In Section 5.1,
352 the convergence behavior of these schemes is analyzed for a mildly and highly anisotropic test
353 case. In Sections 5.2 and 5.3, we compare these schemes to the Box method [28, 29] that uses
354 finite-element basis functions on each cell to calculate fluxes over sub-volume faces. Further, in
355 Section 5.2 discrete extremum principles are investigated and in Section 5.3 benchmark test cases
356 are considered. So far, the reconstruction operator I_σ has not been specified. From now on, the
357 harmonic averaging interpolator (42) is used.

358 For measuring the coercivity of the scheme, the following estimate is defined

$$e_{\mathcal{T}}(u, v) \stackrel{\text{def}}{=} \frac{a_{\mathcal{T}}(u, v, v)}{\|v\|_{\mathcal{T}}}. \quad (62)$$

359 The impact of the term $R_{K,\sigma}(u, v)$ in the NLTPFA expression is quantified with

$$e_R(u, v) \stackrel{\text{def}}{=} \max_{K \in \mathcal{T}, \sigma \in \mathcal{E}_K} |R_{K,\sigma}(u, v)|. \quad (63)$$

360 For simplicity, we define $e_{\mathcal{T},n} \stackrel{\text{def}}{=} e_{\mathcal{T}}(u_n, u_n)$, $\bar{e}_{\mathcal{T},n} \stackrel{\text{def}}{=} e_{\mathcal{T}}(u_n, u_n - \bar{u})$, and analogously $e_{R,n}, \bar{e}_{R,n}$.

361 All simulations are performed using the open-source simulator DuMu^x [30], which comes in
362 the form of an additional *DUNE* module [31]. Newton's method is used for solving the occurring
363 nonlinear systems of equation. The nonlinear iteration loop is stopped if the absolute residual

is below 10^{-5} . The optimization problem (22) is solved using a *Primal-Dual Simplex Method* provided by the open-source library *GNU Linear Programming Kit*¹ (GLPK).

5.1. Convergence rates

Within this section, the computational domain is chosen as $\Omega = [0, 1]^2$. Furthermore, Dirichlet conditions are set on the whole boundary consistent with the exact solution. The grids that are used to analyze the convergence behavior of the schemes are shown in Figure 2. These meshes are refined such that the pattern remains unaffected.

Figure 2: Grids used for the convergence tests. From left to right: non-matching, randomly distorted and twisted grid.

The first test case analyzes the convergence rates for a homogeneous mildly anisotropic tensor

$$\Lambda = \begin{pmatrix} 1.0 & 0.5 \\ 0.5 & 1.0 \end{pmatrix}, \quad (64)$$

with the exact solution $\bar{u}(x, y) = 1 + \sin(\pi x) \sin(\pi y)$ and the corresponding source term as $f = -\nabla \cdot (\Lambda \nabla \bar{u})$.

Table 1–3 list the error norms for the NLTPFA, NLMPFA and AvgMPFA schemes. It is observed that all schemes converge approximately with second order in the L^2 -norm and at least first order in the H^1 -norm. Furthermore, the coercivity estimates $e_{\mathcal{T},n}$, $\bar{e}_{\mathcal{T},n}$ seem to be bounded. The number of Newton iterations are quite small for the NLTPFA scheme. The Newton method converges within three iterations, whereas the NLMPFA method needs approximately 3 – 6 iterations.

In the next example, the tensor is changed to investigate the behavior for high anisotropy ratios.

$$\Lambda(x, y) = \frac{1}{x^2 + y^2} \begin{pmatrix} \beta x^2 + y^2 & (\beta - 1)xy \\ (\beta - 1)xy & x^2 + \beta y^2 \end{pmatrix}, \quad (65)$$

with $\beta = 10^{-3}$. The exact solution is the same than in the previous example. The anisotropy ratio is given as $\frac{1}{\beta}$. The integrated source term and the averaged tensor $\langle \Lambda \rangle_K$ are calculated using a fifth-order quadrature rule. For this test case, faces exist where the conormal cannot be decomposed with only positive coefficients. Negative coefficients especially occur on the randomly distorted grid. Therefore, the calculation of $e_{R,n}$, $\bar{e}_{R,n}$ is included. Please note that these values are rounded to the eighth decimal place.

Table 4–6 list the error norms of the NLTPFA, NLMPFA and AvgMPFA schemes for the high anisotropy test case. It is observed that all schemes converge approximately with order 1.5–2.0 in the L^2 -norm and order 0.7–2.0 in the H^1 -norm. Furthermore, the coercivity estimates $e_{\mathcal{T},n}$, $\bar{e}_{\mathcal{T},n}$ seem to be bounded. However, the behavior of $\bar{e}_{\mathcal{T},n}$ is unclear for the non-matching grid. The number of Newton iterations are again quite small for the NLTPFA scheme. The Newton method

converges within three iterations, whereas, the NLMPFA needs more iterations. In particular for the randomly distorted grid, the number of Newton iterations increases with grid refinement for the NLMPFA scheme. Moreover, the estimates $e_{R,n}$, $\bar{e}_{R,n}$ are quite small and bounded, such that this term is in $\mathcal{O}(1)$.

In the last examples, it has been observed that the convergence behavior of the NLTPFA, NLMPFA and AvgMPFA schemes is quite similar. Furthermore, the schemes seem to be coercive for these test cases. The main drawback of the NLMPFA scheme is the fact that it requires more Newton iterations, and that the number of iterations partly depends on the discretization length $h_{\mathcal{D}}$.

5.2. Discrete extremum principles

The following two examples investigate whether the schemes satisfy discrete extremum principles. In the first example, the tensor (65) is again considered. The boundary conditions are $u = 0$ on $\partial\Omega$ and $\Omega = [0, 1]^2$ is discretized with a regular cartesian grid. The source term is $f = 10$ in $(0.5, 1)^2$ and $f = 0$ elsewhere. The weak solution of this test problem is positive within the domain, because of the non-negativity of the source term and the chosen boundary conditions. Figure 3 shows the numerical results of the Box, AvgMPFA, NLTPFA and NLMPFA schemes. It can be seen that the linear schemes produce unphysical negative solution values, whereas the undershoots produced by the nonlinear schemes are in the range of the solver tolerance.

The next example investigates another test case without a source term. The domain and the grid are shown in Figure 4, with an inner and an outer boundary. The Dirichlet values $u = 10^5$ and

$u = 0$ are set at the inner and outer boundaries, respectively. Therefore, the solution is expected to be within these bounds.

Figure 5 shows the numerical solutions of the Box, AvgMPFA, NLTPFA and NLMPFA schemes on a three times refined grid. All schemes fulfill the maximum principle, whereas the minimum principle is violated by the linear schemes. The undershoots of the AvgMPFA scheme are above 4% and those of the Box scheme above 2%.

The small negative undershoots of the nonlinear schemes are caused by Newton's method. These undershoots can be prevented by using other nonlinear solvers such as Picard's method or enhanced solvers [32].

The above test cases exhibit how nonlinear schemes are capable to reproduce physical solutions, whereas linear schemes can produce negative values. When solving highly complex partial

differential equations, where secondary variables non-linearly depend on primary variables, such negative values can strongly influence the efficiency of the scheme, in terms of linear and nonlinear solver convergence.

5.3. Benchmark examples

In this last section, three-dimensional benchmark test cases are considered. The first example investigates the linearity-preservation property of the schemes. The considered domain and the grid are shown in Figure 6 (right). The domain consists of two sub-domains Ω_1 and Ω_2 . The

	7	1.14e-04	1.93	2.78e-03	1.89	1.41	0.33	0	0	1

transition from Ω_1 to Ω_2 is located at $x = 0.6$, and the permeability tensors are chosen as

$$\Lambda_1 = \begin{pmatrix} 3 & 1 & 0 \\ 1 & 3 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad \Lambda_2 = \begin{pmatrix} 10 & 3 & 0 \\ 3 & 10 & 0 \\ 0 & 0 & 1 \end{pmatrix}. \quad (66)$$

The exact solutions in the sub-domains are

$$\bar{u}_1 = 14x + y + z, \quad \bar{u}_2 = 4x + y + z + 6. \quad (67)$$

Figure 6 (left) depicts the exact solution. Please note that the exact solution and the corresponding flux function are globally continuous within the domain. It can also be seen that the grid is non-matching at the transition of the sub-domains. Such non-matching grids often occur in faulted geological environments. The grid in Figure 6 is defined by means of the standard corner-point

Figure 3: Solution of Box, AvgMPFA, NLTPFA and NLMPPFA schemes for the first extremum principle test case.

grid format and has been generated with the *Matlab Reservoir Simulation Toolbox* (MRST) [33].
 To read in the grid, the *opm-grid* module from the *Open Porous Media (OPM) initiative*² has
 been used.

Table 7: Discrete error norms, number of non-zero entries in the Jacobian matrix (nnz) and the number of Newton iterations (nIt) needed for the linearity-preservation test case.

scheme	$\ u_n - \bar{u}\ _{L^2}$	$\ u_n - \bar{u}\ _{\mathcal{T}}$	nnz	nIt

TPFA	9.11e-03	3.92e-01	107600	1

Table 7 lists the discrete error norms, the number of non-zero entries in the Jacobian matrix (nnz) and the number of Newton iterations (nIt) needed for the simulation run. It can be seen that the NLTPFA, the NLMPPFA and the AvgMPFA all reproduce the exact solution, because the

²<http://opm-project.org/>

Figure 4: Unstructured grid used for the second discrete extremum principle test case.

errors are within the range of the nonlinear and linear solver tolerance, whereas the errors of the linear TPFA scheme are approximately five orders of magnitude higher. It is well-known that the errors of the linear TPFA scheme are in $\mathcal{O}(1)$ for non-K-orthogonal grids. However, the improved accuracy of the other schemes comes with the cost of a larger face flux stencil, which is the reason why the corresponding Jacobian matrices are denser than the one of the TPFA scheme. When using Picard's method instead of Newton's method, the number of non-zero entries would be the same for the NLTPFA and TPFA scheme.

451

The next example is a synthetic model of sedimentary basin inspired by the 3D *Northeast German Basin* model presented in [34]. An approximate geometry of the basin was reconstructed using the software TemisFlow developed at IFPEN. For that case, the stationary heat equation is solved, where, here, Λ corresponds to the thermal conductivity $[\text{W}/(\text{m} \cdot \text{K})]$ and u to the temperature $[\text{K}]$. The thermal conductivity has been computed using the following law

$$\Lambda = \left(\frac{\Lambda_w}{\Lambda_s} \right)^\phi \frac{\Lambda_s}{1 + \alpha u},$$

where α is a coefficient used to express the thermal dependency, Λ_w and Λ_s denote the water and rock conductivities, and ϕ the porosity. A vertical geothermal gradient was assumed initially to evaluate the law. Salt diapirs within this model create high conductive regions, as shown in Figure 7, leading to thermal anomalies. A robust discretization with respect to the grid is required for this type of structure, in order to evaluate the temperature field and to perform thermohaline simulations. At the top and bottom boundaries, Dirichlet conditions are set to 281.15 K and 423.15 K, respectively, whereas Neumann no-flow conditions are used elsewhere.

Figure 8 (a)-(c) show the numerical solutions of the TPFA, NLTPFA and the Box scheme. Additionally, the absolute difference between the TPFA and the NLTPFA is depicted in Figure 8 (d). It is observed that the TPFA scheme differs from the NLTPFA and Box scheme especially at

Figure 5: Solution of Box, AvgMPFA, NLTPFA and NLMPFA schemes for the second discrete extremum principle test case.

the salt domes, where it seems that the TPFA scheme overestimates the temperature values.

Table 8 lists the discrete error norms $\|u_1 - u_2\|_{L^2}$ between the schemes. Please note that the total domain volume is approximately $|\Omega| \approx 1.75e14 \text{ m}^3$, which explains why the errors are quite large. All schemes differ at most from the TPFA scheme, which shows a better accuracy of the schemes compared to a TPFA.

Table 8: Discrete error norms $\|u_1 - u_2\|_{L^2}$ between the different schemes.

scheme	NLTPFA	NLMPFA	AvgMPFA	TPFA	Box	nnz	nIt
NLTPFA	0	9.09e06	2.28e06	6.69e07	2.27e07	11967982	6
NLMPFA	9.09e06	0	8.98e06	6.57e07	2.26e07	11969149	9
AvgMPFA	2.28e06	8.98e06	0	6.69e07	2.26e07	11967982	1
TPFA	6.69e07	6.57e07	6.69e07	0	7.84e07	5974567	1
Box	2.27e07	2.26e07	2.26e07	7.84e07	0	23684992	1

Again, the number of non-zero entries of the NLTPFA, NLMPFA and AvgMPFA is approximately twice the number of the TPFA scheme. Moreover, the most dense matrix is the one of the

Figure 6: Exact solution for linearity-preservation test case (left); Grid used for the spatial discretization (right).

Figure 7: Thermal conductivity of the Northeast German Basin. The salt domes correspond to the high conductive regions. The domain lengths in coordinate directions are approximately 169 km (in the x-direction), 165 km (in the y-direction), and 17.57 km (in the z-direction).

474 Box scheme.

475 6. Conclusion

476 In this article, a family of cell-centered finite volume schemes has been introduced and analyzed.
 477 The construction of these schemes is based on a convex combination of two face flux approxima-
 478 tions. These face flux approximations are designed to satisfy a strong consistency condition by
 479 choosing an appropriate face interpolator.

480 In the first part of this work, a proof of the convergence of this family of schemes has been
 481 given. In Section 4, two representatives of this family have been constructed, namely the non-
 482 linear two-point flux approximation (NLTPFA) and the nonlinear multi-point flux approximation
 483 (NLMPFA), such that the strong consistency assumption is fulfilled. To guarantee the existence
 484 of a discrete solution, the discrete flux approximations have been modified to be continuous in

Figure 8: Solution of TPFA, NLTPFA and Box scheme (a)-(c). Absolute difference of TPFA and NLTPFA scheme (d). The results are shown for a part of the domain.

485 $H_{\mathcal{T}_n}(\Omega)$. Moreover, the NLTPFA scheme has been extended to the case where negative coefficients
 486 arise in the conormal decomposition. This has been achieved by reformulating the residual term
 487 in the flux approximation.

488 Finally, in Section 5, the nonlinear schemes have been compared to linear ones. The con-
 489 vergence behavior has been analyzed for a mild and high anisotropy test case on non-matching,
 490 randomly distorted and twisted grids. It has been observed that there are almost no differences
 491 in the convergence rates between the linear AvgMPFA and the nonlinear schemes. In addition to
 492 that, estimates have shown the coercivity of the schemes for the considered test cases. The main
 493 difference between the NLTPFA and the NLMPFA is the number of Newton iterations needed for
 494 convergence. For all test cases, the NLTPFA requires less iterations than the NLMPFA scheme.
 495 The positivity-preserving property of the nonlinear schemes has been analyzed in Section 5.2,
 496 where it has been shown that linear schemes produce unphysical negative values, in contrast to
 497 the nonlinear ones. In Section 5.3, it has been demonstrated that the introduced schemes are
 498 linearly exact on non-matching grids. Furthermore, the schemes have been applied to a synthetic
 499 geological formation inspired by the Northeast German Basin, to solve the stationary heat equa-
 500 tion with heterogeneous thermal conductivities. It has been shown that the standard linear TPFA
 501 scheme overestimates the temperature in salt domes, whereas the NLTPFA, NLMPFA, AvgMPFA
 502 and Box schemes all exhibit similar behavior.

503 Within this work, only linear elliptic problems have been considered. Therefore, using a non-
 504 linear discretization method obviously deteriorates the efficiency of the computations compared to

linear schemes. However, this drawback vanishes when solving highly nonlinear partial differential equations [21].

Proposition 3 (Density of a space of test-functions). *Under Hypotheses 2, let $\mathcal{Q}$ be the space of functions $\varphi : \overline{\Omega} \rightarrow \mathbb{R}$ s.t.*

- (i) (φ is continuous and piecewise regular) $\varphi \in C_0(\overline{\Omega})$ and, for all $i = 1, \dots, N_\Omega$, $\varphi \in C^2(\overline{\Omega}_i)$,
- (ii) (the tangential derivatives of φ are continuous through the interfaces of P_Ω) for all $i, j = 1, \dots, N_\Omega$, for all vectors $\mathbf{t}$ parallel to $\partial\Omega_i \cap \partial\Omega_j$, $(\nabla\varphi)_{|\overline{\Omega}_i} \cdot \mathbf{t} = (\nabla\varphi)_{|\overline{\Omega}_j} \cdot \mathbf{t}$ on $\partial\Omega_i \cap \partial\Omega_j$, where $(\nabla\varphi)_{|\overline{\Omega}_i}$ refers to the value of $\nabla\varphi$ on $\partial\Omega_i$ computed from the values on $\overline{\Omega}_i$,
- (iii) (the flux of $\nabla\varphi$ directed by $\Lambda\mathbf{n}$ is continuous through the interfaces of P_Ω) for all $i, j = 1, \dots, N_\Omega$ s.t. $\partial\Omega_i \cap \partial\Omega_j$ has dimension $d - 1$, $(\Lambda\nabla\varphi)_{|\overline{\Omega}_i} \cdot \mathbf{n}_i + (\Lambda\nabla\varphi)_{|\overline{\Omega}_j} \cdot \mathbf{n}_j = 0$ on $\partial\Omega_i \cap \partial\Omega_j$, where $\mathbf{n}_i$ is the outer normal to Ω_i .

Then, $\mathcal{Q}$ is dense in $H_0^1(\Omega)$.

Proof. see [4]. □

Proposition 4 (Discrete Sobolev embeddings). *Let $\mathcal{D}$ be an element of a family of discretizations matching Definition 1. Let $q \in [1, +\infty)$ if $d = 2$, and $q \in [1, 2d/(d - 2)]$ if $d > 2$. Then, there exists a strictly positive parameter $C_2 > 0$ depending only on Ω , q , ϱ_1 and ϱ_2 s.t.*

$$\|u\|_{L^q(\Omega)} \leq C_2 \|u\|_{\mathcal{T}} \quad \forall u \in H_{\mathcal{T}}(\Omega).$$

Proof. This result can be proved following the guidelines of the proof in [12, §5.1.2], since all discrete norms considered in this work are equivalent under the mesh regularity assumptions of Definition 1. □

Theorem 2 (Discrete Rellich theorem). *Let $\{\mathcal{D}_n\}_{n \in \mathbb{N}}$ be a sequence of admissible discretizations matching Definition 1 s.t. $h_{\mathcal{D}_n} \rightarrow 0$ as $n \rightarrow \infty$. Let $\{v_n\}_{n \in \mathbb{N}}$ be a sequence in $H_{\mathcal{T}_n}(\Omega)$ s.t. there exists $C > 0$ with $\|v_n\|_{\mathcal{T}_n} \leq C$ for all $n \in \mathbb{N}$. Then, there exist a subsequence of $\{v_n\}_{n \in \mathbb{N}}$ and a function $\tilde{v} \in H_0^1(\Omega)$ s.t., as $n \rightarrow \infty$, (i) $v_n \rightarrow \tilde{v}$ in $L^q(\Omega)$ for all $q \in [1, 2d/(d - 2))$ (and weakly in $L^{2d/(d-2)}(\Omega)$ if $d > 2$); (ii) $\{\tilde{\nabla}_{\mathcal{D}_n} v_n\}_{n \in \mathbb{N}}$ weakly converges to $\nabla\tilde{v}$ in $[L^2(\Omega)]^d$.*

Proof. This theorem deduces from (11) using the same techniques as for [12, Lemmata 5.6–5.7]. □

Proposition 5 (Asymptotic stability of the interpolator). *Under Hypotheses 1, we have*

$$\|\varphi_{\mathcal{T}}\|_{\mathcal{T}} \leq \frac{1}{\gamma_1} \left(\epsilon_{\mathcal{D}}(\varphi) + \beta_0 \sqrt{d} |\varphi|_{H^1(\Omega)} \right)$$

for all $\varphi \in \mathfrak{D}$.

533 *Proof.* Let $\varphi \in \mathfrak{D}$. Owing to (P2), we get

$$\begin{aligned} \gamma_1 \|\varphi_{\mathcal{T}}\|_{\mathcal{T}}^2 &\leq a_{\mathcal{T}}(\varphi_{\mathcal{T}}, \varphi_{\mathcal{T}}, \varphi_{\mathcal{T}}) \\ &= \left(a_{\mathcal{T}}(\varphi_{\mathcal{T}}, \varphi_{\mathcal{T}}, \varphi_{\mathcal{T}}) - \int_{\Omega} \Lambda \nabla \varphi \cdot \tilde{\nabla}_{\mathcal{D}} \varphi_{\mathcal{T}} \, dx \right) + \int_{\Omega} \Lambda \nabla \varphi \cdot \tilde{\nabla}_{\mathcal{D}} \varphi_{\mathcal{T}} \, dx \\ &\leq \epsilon_{\mathcal{D}}(\varphi) \|\varphi_{\mathcal{T}}\|_{\mathcal{T}} + \beta_0 |\varphi|_{H^1(\Omega)} \|\tilde{\nabla}_{\mathcal{D}} \varphi_{\mathcal{T}}\|_{[L^2(\Omega)]^d} \leq \left(\epsilon_{\mathcal{D}}(\varphi) + \beta_0 \sqrt{d} |\varphi|_{H^1(\Omega)} \right) \|\varphi_{\mathcal{T}}\|_{\mathcal{T}}. \quad \square \end{aligned}$$

534 **Proposition 6** (Stability). *Assume that Hypotheses 1 hold. Then, any solution $u_n \in H_{\mathcal{D}_n}(\Omega)$ of*
 535 *problem (4) for a given $n \in \mathbb{N}$ satisfies the stability estimate*

$$\|u_n\|_{\mathcal{T}_n} \leq \frac{C_2}{\gamma_1} \|f\|_{L^r(\Omega)}. \quad (68)$$

536 *Proof.* Using the fact that $f \in L^r(\Omega)$ and thanks to (P2), Hölder's inequality and Proposition 4,
 537 we have

$$\gamma_1 \|u_n\|_{\mathcal{T}_n}^2 \leq a_{\mathcal{T}_n}(u_n, u_n, u_n) = \int_{\Omega} f u_n \, dx \leq \|f\|_{L^r(\Omega)} \|u_n\|_{L^{r'}(\Omega)} \leq C_2 \|f\|_{L^r(\Omega)} \|u_n\|_{\mathcal{T}_n},$$

538 with $r' \stackrel{\text{def}}{=} \frac{r}{r-1} = \frac{2d}{d-2}$. □
