A Simultaneous Localization and Mapping Algorithm Based on Kalman Filtering

H. Chou, M. Traonmilin, E. Ollivier, M. Parent

Abstract—For automatic navigation of autonomous vehicles, localization in real time is a key issue. In this article, a simultaneous localization and mapping algorithm is proposed for an autonomous vehicle. We use a laser detection and ranging sensor to detect the operating environment. An environment map is plotted out using the sensor output data. Then, with an odometer, the vehicle position is located on this map. Finally, these two sensor outputs are merged using a Kalman filter to correct the map as well as the vehicle position.

I. INTRODUCTION

Automatic navigation of an autonomous vehicle involves following a planned trajectory taking the vehicle from a start configuration to a goal configuration. The desired trajectory can be viewed as a collection of vehicle configurations, which describe the vehicle’s location and orientation with respect to the world coordinate system.

One of the major difficulties, however, for this automatic navigation task, is to know the exact location and orientation of the vehicle during its operation. Due to the unavoidable measurement errors, the vehicle configuration is never precisely, if not poorly, determined.

In some previous research work, self positioning systems have been divided into three basic technologies [3], [10]: stand alone (e.g. odometer, inertial navigating), satellite-based (e.g. global positioning system), and terrestrial radio-based (e.g. cellular networks). Other landmark-based or map-based approaches have also been proposed which use ultrasonic, sonar, or laser range sensors [2], [6].

In fact, each of these approaches has its own disadvantages and estimation limits. With Odometer, the error due to wheel slips could not be eliminated and will keep adding up. Inertial navigating system (INS) is sensitive to vibration, noise and has temperature dependent measurement drifts. The accuracy range of global positioning system (GPS) is often several meters.

Thus, some hybrid positioning systems have been studied using two or more of the above technologies. The best example would be combinations of odometers, GPS, and INS sensors to locate vehicle position [1], [5], [10]. Based on the fact that INS provides high-rate position, velocity, and attitude data with good short-term stability while the GPS provides position and velocity data with a good long-term stability [13], integrating the GPS with the INS has been largely used recently as a localization solution.

But with GPS and INS, the costs usually become quite expensive if we want to raise the precisions. Since autonomous vehicles are often equipped with a detection and ranging sensor to avoid collision, we propose a data merging algorithm using both laser detection and ranging (lidar) sensor and odometer data to plot out the environment map and to locate the vehicle position.

The paper is outlined as follows. In section II, a simple bicycle mathematical model is given for the vehicle in order to design our localization algorithm. Then, in section III our algorithm is explained in detail. A Kalman filter which merge the sensor data and correct the final map plot is described. The structure of our experiment platform, a prototype electric car “CyCab” designed for autonomous navigation, is described in section IV. The algorithm is implemented and tested on CyCab and the result is shown in section V. Finally, we give a conclusion and discuss the future perspective of our research work in section VI.

II. VEHICLE MODEL

The mathematical model we use to develop the algorithm is a very simple planer model. We suppose that the vehicle behaves as a bicycle and that the wheels do not slip. The four-wheel-vehicle can be then drawn as shown in figure 1 with only two wheels.

![Bicycle model](image)

Fig. 1. Bicycle model.

From the above assumptions, we can write down the following equations in the vehicle’s coordinate system:

\[
\begin{align*}
V_{1x} &= V_{2x} = V_{ox} \\
V_{1y} &= V_{oy} + L_1 \dot{\psi} = L \dot{\psi} \\
V_{2y} &= V_{oy} - L_2 \dot{\psi} = 0 \\
\dot{\psi} &= \frac{V_{ox}}{L} \tan \alpha.
\end{align*}
\]  

(1)

where \( V_{1x}, V_{2x}, \) and \( V_{ox} \) are the longitudinal velocities of the front wheel, the rear wheel, and the center of gravity.
in the vehicle's coordinate system, $V_{1y}$, $V_{2y}$, and $V_{og}$ are the lateral velocities of the front wheel, the rear wheel, and the center of gravity in the vehicle's coordinate system, $\psi$ is the yaw angle, $\alpha$ is the steering angle.

If $V = (V_{og}, V_{og})'$ denote the velocity in the vehicle's coordinate system and $V_G = (V_{Gx}, V_{Gy})'$ denote the velocity in the global coordinate system, we have the following relationship:

$$V_G = RV$$  \(2\)

where $R$ stands for the transformation matrix from the vehicle coordinate to the world coordinate.

This very simple cinematic model will be used in the following section to determine in a first step the position and yaw angle of the vehicle. And then a Kalman filter based on the same model will be designed to correct the position on a map generated with the ladar data.

### III. ALGORITHM

The goal of our research is to construct an algorithm that can plot out the map of the unknown environment in which the vehicle is operating, while at the same time, estimate and locate the vehicle’s position on the generated map.

#### A. General Philosophy

We have chosen to use this stochastic map concept which was developed in the 80’s. This concept allows us to integrate data from the two different information sources we have (ladar and odometer) and to estimate statistically the vehicle states and the environment states at the same time by using a Kalman filter. Figure 2 shows the data flow and data processing diagram of our algorithm.

First, the ladar scan plots out the operating environment map. An extracting algorithm locates objects in the operating environment and plot their positions to form a map. While the vehicle moves forward, the odometer integration algorithm estimates the vehicle position and also object positions in relation to the vehicle. Then, with a Kalman filter algorithm, we correct the object positions, thus the map, and also the vehicle positions on the map.

#### B. System Equations for Extended Kalman Filter

A Kalman filter is a recursive, linear, optimal, real time data processing algorithm which is used to estimate the states of a dynamic system in a noisy environment. It addresses the general problem of trying to estimate the state of a discrete-time controlled process that is governed by a linear stochastic difference equation. But since our system is non-linear, we try to linearize it about the current mean and covariance, and this is referred to as an extended Kalman filter [4].

From the equations (1) and (2), we can get the following discrete equations:

$$\begin{align*}
    x_k &= x_{k-1} + \Delta l_k \cos \psi_{k-1} \\
    y_k &= y_{k-1} + \Delta l_k \sin \psi_{k-1} \\
    \psi_k &= \psi_{k-1} + \frac{\Delta l_k}{L} \tan \alpha_k
\end{align*}$$  \(4\)

where $x_k$, $y_k$, and $\psi_k$ are the longitudinal, lateral position and yaw angle of the vehicle respectively in the world coordinate at $k^{th}$ time instant, $\Delta l_k = V_{og} \Delta t$ is the driving distance in $k^{th}$ time interval $\Delta t$. Please notice that this discrete model is just a approximation of the continuous system.

As the objects in the operating environment don’t move, their positions can be expressed as follow:

$$\begin{align*}
    x_{Gk}^i &= x_{Gk-1}^i \\
    y_{Gk}^i &= y_{Gk-1}^i
\end{align*}$$  \(5\)

$x_{Gk}^i$ and $y_{Gk}^i$ $(i = 1 \sim n)$ are the position of the $i^{th}$ object in the world coordinate system.

So with equations (4) and (5), we can now form a discrete system to design our Kalman filter:

$$\begin{align*}
    X_k &= F(X_{k-1}, \Delta l_k, \alpha_k) + v_{k-1} \\
    Y_k &= H(X_k) + w_k
\end{align*}$$  \(6\)

with $v_k$ and $w_k$ the state variables noise and measurement noise respectively. The state variables $X_k$ and measurement
output $Y_k$ at time instant $k$ are chosen as:

$$\begin{bmatrix} x_k \\ y_k \\ \psi_k \\ x_{\theta k} \\ y_{\theta k} \\ \vdots \\ x_{\theta n} \\ y_{\theta n} \end{bmatrix}, \quad Y_k = \begin{bmatrix} x_{\theta k} \\ y_{\theta k} \\ \vdots \\ x_{\theta n} \\ y_{\theta n} \end{bmatrix}.$$  

The measurement output we get from the ladar are the object positions in the vehicle's coordinate system, which can be expressed as:

$$\begin{bmatrix} x_{\theta k} \\ y_{\theta k} \end{bmatrix} = H^i(X_k) = R^T \begin{bmatrix} x_{\theta k} - x_k \\ y_{\theta k} - y_k \end{bmatrix} + w_{k, i}.$$  

for $i = 1 \sim n$.

Thus, the linearized system equations of the system (6) can be written as:

$$\begin{align*}
X_k &= F(X_{k-1}, v_{k-1}) + v_k \\
Y_k &= H_k X_k + w_k,
\end{align*}$$

with

$$F_k = \frac{\partial F}{\partial X} \bigg|_{X_k},$$

and

$$H_k = (\frac{\partial H^1}{\partial X} \ldots \frac{\partial H^n}{\partial X}) \bigg|_{X_k}.$$  

C. Extended Kalman filter

The extended Kalman filter estimates a nonlinear system by using a form of feedback control: the filter estimates the system state variables at first and then obtains feedback in the form of measurements. Thus, the equations for the extended Kalman filter are divided into two groups: prediction equations and correction equations. It is shown in the following:

Prediction step:

$$\begin{align}
\dot{X}_k^- &= F(\dot{X}_{k-1}, \Delta \dot{X}_k, \alpha_k), \\
P_k^- &= F_k P_{k-1} F_k^T + v_{k,1} Q_{k-1} v_{k,1}^T.
\end{align}$$  

Correction step:

$$\begin{align}
K_k &= P_k^- H_k^T (H_k P_k^- H_k^T + w_{k,1} R_{k-1} w_{k,1}^T)^{-1}, \\
\dot{X}_k &= \dot{X}_k^- + K_k (Y_k - H(X_k^-)), \\
P_k &= (I - K_k H_k) P_k^-.
\end{align}$$

where $Q$ is the state noise covariance, $R$ is the measurement noise covariance, $P$ is the error covariance, and $K$ is the Kalman gain.

The prediction equations are responsible for projecting forward (in time) the current state and error covariance estimates to obtain the $a$ priori estimates for the next time step (i.e. $X_k^-$). The correction equations are responsible for the feedback for incorporating a new measurement into the $a$ priori estimate to obtain an improved $a$ posteriori estimate (i.e. $\dot{X}_k$).

IV. EXPERIMENT PLATFORM ARCHITECTURE DESCRIPTION

The researchers of INRIA are working since 1991 on a new intelligent transportation system for the cities of tomorrow. We study in particular on two different concepts: car-sharing and the intelligent vehicle. A small electric vehicle named CyCab (see figure 3) has been designed exactly to fulfill these two situations, especially for zones with limited access to regular automobiles. It can transport up to two persons in downtown areas, pedestrian malls, large industrial or amusement parks and airports, at a maximum of 30km/h speed.

The prediction equations are responsible for projecting forward (in time) the current state and error covariance estimates to obtain the $a$ priori estimates for the next time step (i.e. $X_k^-$. The correction equations are responsible for the feedback for incorporating a new measurement into the $a$ priori estimate to obtain an improved $a$ posteriori estimate (i.e. $\dot{X}_k$).

A. CyCab

This revolutionary urban transportation vehicle is equipped with one computer to coordinate low level servo controls, one computer to realize high level HMI communication, a linear camera for platoon driving, a ladar sensor for anti-collision applications, a steering wheel angle encoder, and an odometer.

The ladar sensor (see figure 4) is mounted to the front of our CyCab. It has a measurement range of at least 50m, with a distance resolution of 4mm and accuracy of 5cm. The scan frequency is at 10Hz. It can give us a robust measurement of the objects in its scanning range.

The encoder is installed in the differential gearbox located in the middle of the rear wheel axle. The resolution of the encoder is 100 pulses per revolution. It gives us the

![Figure 3. Autonomous urban vehicle “CyCab”.](image-url)
driving distance of the vehicle at a frequency of 100Hz.
Together with the steering angle data, vehicle location can
be estimated through the equation (4).
All the data transmission and servo control commands are
managed by the low level servo control computer through
CAN bus. These data can also be read and write by the high
level HMI computer through the low level servo control
computer as shown in figure 5.

B. Data Acquisition and Processing
The data acquisition and processing job for our CyCab
is done with a data logging software “RTMAPS” running
on the high level HMI computer.
RTMAPS, “Real Time Mines Automotive Prototyping
System” [9] is a software platform designed to acquire,
and also to replay, time-stamped and synchronized data
stemming from a multisensor system. It allows us to record
all the sensor data in a databases without any loss, and then
to replay it on a standard computer in the same conditions
when they have been recorded.
With the recorded database, we can use RTMAPS fa-
cilities (interfaced with Matlab, Excel, Scilab) to analyze
these data off-line, and then develop new algorithms using
multiple programming languages (C/C++, Java, VB
Basic). When algorithms and applications have been validated in
the laboratory, they can immediately be put into the vehi-
cle’s RTMAPS environment, and tested with real hardware.

Figure 6 gives an example of the user interface of
RTMAPS. Sensors, actuators, and even user defined al-
gorithms can be represented as components in RTMAPS’
environment. The graphic interface allows users to visualize
the connections and data flows between components. Using
this accurate dating system, synchronizing real time data
flows for different sensors and actuators has also become
very easy.

V. EXPERIMENT RESULT
Our simultaneous map-plotting and localization algo-
rithm was tested on the prototype electric car “CyCab”
designed especially for INRIA.

A. Experiment Setup
First, we have placed some poles in the testing envi-
ronment. The poles were of 90cm tall, 5cm in diameter,
and were randomly placed. The reason of using poles to
represent environment installation is because its simple
geometry properties are easier to identify for a preliminary
algorithm.
A driving test of a straight line was carried out in the
testing environment using manual driving mode of CyCab
with a driver on board. Our algorithm was launched on
the high level HMI computer using the platform RTMAPS
before the test. During the test, odometer and ladar sensor
data were collected by the low level servo control computer,
passed to the high level computer. Data were treated and
environment map as well as vehicle position were plotted
in real time with RTMAPS on the screen on board as the
CyCab was moving forward. The processing rate of our
algorithm is at the frequency of the ladar sensor, which
means the mapping and locating is updated every 100ms.

B. Experiment Result
The resulting map and driving trajectory was recorded
and plotted as shown in figure 7. We can see that the
cross points are the poles located by the ladar sensor and
extracted with a preliminary recognition algorithm. Other environment obstacles are also drawn out with solid lines on the map.

![Graph](image)

Fig. 7. Experimental Result.

The black trajectory is traced out using only odometer data while the gray trajectory is the result of data merging and map correcting. With only odometer, the error can build up to 10m in a test distance of only 35m, which is not acceptable at all. This is due to the measurement error on the steering angle and other measurement noise. These errors can build up throughout time when we estimate the vehicle position using equation (1).

On the other hand, the error is only a few centimeters with our data merging and map correcting algorithm using Kalman filtering technique.

VI. CONCLUSION AND FUTURE PERSPECTIVE

In this research work, a real time localization solution with a reasonable error and a small budget using ladar sensor and odometer is studied. A simultaneous map-plotting and localization algorithm is proposed using Kalman filter to merge collected data and to correct the resulting map plot. We show that our algorithm has improved significantly the position estimating result using only odometer data. Since autonomous vehicles are often equipped already with a detection and ranging sensor to avoid collision, the main advantage of our algorithm is that no extra sensors are needed in order to carry out the localization task.

The future perspective would be to integrate some cartographic data into the system and to use a map-matching algorithm to give us the exact position for a localization task of larger scale. Furthermore, a crosswalk recognition algorithm by camera vision could also be included into the algorithm in order to perform larger scale repositioning. Finally, with a trajectory planning algorithm, we can realize a path following control algorithm so that the vehicle could be automatically navigated.
