Cyclotomic quiver Hecke algebras and Hecke algebra of $G(r, p, n)$

Salim Rostam

Abstract

Given a quiver automorphism with nice properties, we give a presentation of the fixed point subalgebra of the associated cyclotomic quiver Hecke algebra. Generalising an isomorphism of Brundan and Kleshchev between the cyclotomic Hecke algebra of type $G(r, 1, n)$ and the cyclotomic quiver Hecke algebra of type $A$, we apply the previous result to find a presentation of the cyclotomic Hecke algebra of type $G(r, p, n)$ which looks very similar to the one of a cyclotomic quiver Hecke algebra. In addition, we give an explicit isomorphism which realises a well-known Morita equivalence between Ariki–Koike algebras.

Introduction

Generalising real reflection groups, also known as finite Coxeter groups, complex reflection groups are finite groups generated by complex reflections, that is, by endomorphisms of $\mathbb{C}^n$ which fix a hyperplane. As for Coxeter groups, there is a classification of irreducible complex reflection groups [(ShTo)]. This classification is given by an infinite series $\{G(r, p, n)\}$ where $r, p, n$ are positive integers with $r = dp$ for $d \in \mathbb{N}^*$, together with 34 exceptional groups.

More precisely, the group $G(r, p, n)$ can be seen as the group consisting of all $n \times n$ monomial matrices such that each non-zero entry is a complex $r$th root of unity, and the product of all non-zero entries is a $d$th root of unity. If $\xi \in \mathbb{C}^\times$ is a primitive $r$th root of unity, the latter group is generated by the elements:

$$s := \xi^p E_{1,1} + \sum_{k=2}^n E_{k,k}, \quad \tilde{t}_1 := \xi E_{1,2} + \xi^{-1} E_{2,1} + \sum_{k=3}^n E_{k,k},$$

$$t_a := E_{a,a+1} + E_{a+1,a} + \sum_{1 \leq k \leq n, \ k \neq a, a+1} E_{k,k}, \quad \text{for all } a \in \{1, \ldots, n-1\},$$

where $E_{k,\ell}$ is the elementary $n \times n$ matrix with 1 as the $(k, \ell)$-entry and 0 everywhere else.

Inspired by work in the context of finite Chevalley groups, an algebra was associated with each real reflection group $W$: the Iwahori–Hecke algebra $H(W)$. This deformation of the group algebra of $W$ was the starting point of many connections with other objects and theories, for instance, the theory of quantum groups or knot theory. Aiming at generalising this construction, Broué, Malle and Rouquier [BMR] defined such a deformation for every complex reflection group, also known as Hecke algebra. Besides, Ariki and Koike [ArKo] defined such a Hecke algebra $H_n(u)$ for $G(r, 1, n)$ where $u = (u_1, \ldots, u_r)$ is a tuple of parameters, followed by Ariki [Ar95] who did the same thing for $G(r, p, n)$. In particular, for a suitable choice of parameters $q$ and $u$, this Hecke algebra $H^A_{p,n}(q)$ of $G(r, p, n)$ can be seen as a subalgebra of $H_n(u)$.

In the semisimple case, Ariki and Koike have determined all irreducible modules for $H_n(u)$. The modular case was treated by Ariki and Mathas [ArMa, Ar01], and also by Graham and Lehrer [GrLe] and Dipper, James and Mathas [DJM], using the theory of cellular algebras. Moreover, in [Ar96], Ariki proved a conjecture of Lascoux, Leclerc and Thibon [LLT]. The theorem has the following consequence in characteristic 0. If all $u_k$ for $1 \leq k \leq r$ are powers of $q$, then determining the decomposition matrix of $H_n(u)$ or the canonical basis of a certain integrable highest weight $\hat{\mathfrak{sl}}_n$-module $L(\Lambda)$ are equivalent.
problems, where $\hat{A}_n$ denotes the Kac–Moody algebra of type $A_{n-1}^{(1)}$. Together with the work of Uglov [Ug], which computes this canonical basis, we are thus able to explicitly describe the decomposition matrix of $H_n(u)$.

Once again in the semisimple case, Ariki [Ar95] used Clifford theory to determine all irreducible modules for $H_n^{(\Lambda)}(q)$. In the modular case, Genet and Jacon [GeJa] and Chlouveraki and Jacon [ChJa] gave a parametrisation of the simple modules of $H_n^{(\Lambda)}(q)$ over $\mathbb{C}$, and Hu [Hu04, Hu07] classified them over a field containing a primitive $p$th root of unity. Furthermore, Hu and Mathas [HuMa09, HuMa12] gave a procedure to compute the decomposition matrix of $H_n^{(\Lambda)}(q)$ in characteristic 0, under a separation condition (where the Hecke algebra is not semisimple in general). Let us also mention the work of Geck [Ge], who deals with the case of type $D$ (corresponding to $r = p = 2$).

Partially motivated by Ariki’s theorem, Khovanov and Lauda [KhLau2] and Rouquier [Rou] independently introduced the algebra $R_n(\Gamma)$, known as a quiver Hecke algebra or KLR algebra. This led to a categorification result:

$$U_q^{-}(\mathfrak{g}_\Gamma) \simeq \bigoplus_{n \geq 0} [\text{Proj}(R_n(\Gamma))],$$

where $U_q^{-}(\mathfrak{g}_\Gamma)$ is the negative part of the quantum group of $\mathfrak{g}_\Gamma$, the Kac–Moody algebra associated with the quiver $\Gamma$, and $\text{Proj}(R_n(\Gamma))$ denotes the Grothendieck group of the additive category of finitely generated graded projective $R_n(\Gamma)$-modules. Moreover, considering some cyclotomic quotients $R_n^{(\Lambda)}(\Gamma)$ of the quiver Hecke algebra, Kang and Kashiwara [KanKa] also proved a categorification result for the highest weight $U(\mathfrak{g}_\Gamma)$-modules.

With $\Gamma$ a quiver of type $A_{n-1}^{(1)}$ and a suitable choice of $u$, we thus obtain a connection between the Ariki–Koike algebra $H_n(u)$ and $R_n^{(\Lambda)}(\Gamma)$. Brundan and Kleshchev [BrKl] (and independently Rouquier [Rou]) gave an explicit isomorphism between these two algebras. In particular, the Ariki–Koike algebra inherits the natural $\mathbb{Z}$-grading of $R_n^{(\Lambda)}(\Gamma)$. Further, Hu and Mathas [HuMa10] constructed a homogeneous (cellular) basis of the Ariki–Koike algebra.

We aim to generalise the previous results concerning $G(r, 1, n)$ to the remaining elements of the infinite series $\{G(r, p, n)\}$ (and thus for all but finitely many complex reflection groups). In this paper, we restrict the isomorphism of [BrKl] to the subalgebra $H_n^{(\Lambda)}(q)$ of $H_n(u)$ (for a suitable choice of $u$), and then study its image in the cyclotomic quiver Hecke algebra $R_n^{(\Lambda)}(\Gamma)$. Our two main results are the following.

- We obtain a cyclotomic quiver Hecke-like presentation for $H_n^{(\Lambda)}(q)$ (see Corollary 4.16).
- We find an isomorphism which makes explicit the Morita equivalence of Ariki–Koike algebras of [DiMa] (see §3.4).

We will first need to generalise the main result of [BrKl]. Surprisingly, combined with a theorem of [Ro], this leads to the isomorphism realising the above Morita equivalence. We then exploit the fact that $H_n^{(\Lambda)}(q)$ is the fixed point subalgebra of $H_n(u)$ for a particular automorphism $\sigma$, the shift automorphism. After some technical work, we obtain the cyclotomic quiver Hecke-like presentation for $H_n^{(\Lambda)}(q)$. We deduce that $H_n^{(\Lambda)}(q)$ depends only on the quantum characteristic and is a graded subalgebra of $H_n(u)$. We note that Boys and Mathas [Bo, BoMa] already studied a restriction of the isomorphism of [BrKl] to the fixed point subalgebra of an automorphism, in order to study alternating (cyclotomic) Hecke algebras. The approach taken here is globally similar, however, we are here able to use a trick of Stroppel and Webster [StWe] to simplify the final proof (see §4.1).

We now give a brief overview of this article. Let $r, p, d, n \in \mathbb{N}^*$ be some integers with $r = dp$, an element $q \neq 0, 1$ of a field $F$, a primitive $p$th root of unity $\zeta \in F^\times$ and $J := \mathbb{Z}/p\mathbb{Z} \simeq (\zeta)$. We set $e \in \mathbb{N}_{>0} \cup \{\infty\}$ the order of $q$ in $F^\times$ and we define $I := \mathbb{Z}/e\mathbb{Z}$ (with $I = \mathbb{Z}$ if $e = \infty$). Finally, we consider a tuple $\Lambda = (\Lambda_{i,j})$ where $(i,j) \in I \times J$ and $\Lambda_{i,j} \in \mathbb{N}$. We begin Section 1 by defining in §1.1 the Hecke algebra $H_n(u)$ of type $G(r, 1, n)$ (the Ariki–Koike algebra), which we write $H_n^{(\Lambda)}(q, \zeta)$ when each $u_k$ is of the form $\zeta^j q^k$. The algebra $H_n^{(\Lambda)}(q, \zeta)$ is generated by some elements $S, T_1, \ldots, T_{n-1}$, subject to relations (1.2b)–
(1.2f) and the “cyclotomic” one:

$$\prod_{i \in I} \prod_{j \in J} (S - \zeta^i q^j)^{\Lambda_{i,j}} = 0$$

(see (1.6)). We define in Proposition 1.9 an important object of this paper, the shift automorphism $\sigma$ of $H_n^\Lambda(q, \zeta)$: it maps $S$ to $S$ and is the identity on the remaining generators $T_1, \ldots, T_{n-1}$. We then start §2.1 by defining the cyclotomic Hecke algebra $H_{p,n}^\Lambda(q)$ of type $G(r,p,n)$. Our definition differs from Ariki’s [Ar95]. However, in Appendix A, after we gave a short proof that $H_{1,n}^\Lambda(q)$ is the usual Ariki–Koike algebra, we prove that if $p \geq 2$ then our definition is equivalent to Ariki’s. In particular, this shows that Ariki indeed defined a Hecke algebra of $G(r,p,n)$ as defined in [BMR] (this fact is mentioned in [BMR] but we did not find any proof in the literature). We then prove in Corollary 1.18 that $H_{p,n}^\Lambda(q)$ is the fixed point subalgebra of $H_{p}^\Lambda(q, \zeta)$ under the shift automorphism. We introduce in §2.3 a divisor $p'$ of $p$, together with the set $J' := \{1, \ldots, p'\}$, such that the map $I \times J' \ni (i, j) \mapsto \zeta^i q^j$ is one-to-one and has the same image as $I \times J \ni (i, j) \mapsto \zeta^i q^j$. We then define a finitely-supported tuple $\Lambda$, indexed by $I \times J'$, associated with the tuple $\Lambda \in \mathbb{N}^{(I \times J)}$ (see Proposition 1.33). We also introduce the notation $H_{p}^\Lambda(q, \zeta)$ and $H_{p,n}^\Lambda(q)$. The reader should not be afraid of confusing the two notations $\Lambda$ and $\Lambda$: we will not use $\Lambda$ after Section 1.

Now let $\Gamma$ be a loop-free quiver with no repeated edges. Let $K$ be the vertex set of $\Gamma$ and let $A$ be a tuple of non-negative integers indexed by $K$. We define in Section 2 the quiver Hecke algebra $R_n(\Gamma)$ and its cyclotomic quotient $R_n^\Lambda(\Gamma)$. In §2.3, given a permutation of the vertices of $\Gamma$, we associate in Theorem 2.14 an automorphism of $R_n(\Gamma)$ and we easily give in §2.3.1 a presentation of the fixed point subalgebra (Corollary 2.27). In contrast, we need a little bit more work in §2.3.2 to do the same thing for the cyclotomic quotient $R_n^\Lambda(\Gamma)$. We give a presentation for the fixed point subalgebra in Theorem 2.43.

We generalise in Section 3 the main result of [BrKl]. The calculations are entirely similar, hence we do not write them down. More precisely, we prove the following $F$-isomorphism (Theorem 3.4):

$$H_n(u) \simeq R_n^\Lambda(\Gamma).$$

The quiver $\Gamma$ is given by $p'$ copies of the cyclic quiver $\Gamma_c$ with $e$ vertices (which is a two-sided infinite line if $e = \infty$), where $u$ is such that the set $\{u_1, \ldots, u_e\}$ is a union of $p'$ orbits for the action of $\langle \rho \rangle$ on $F^\times$. In particular, in the setting of [BrKl] we have $p' = 1$. Moreover, we deduce that this isomorphism realises the well-known Morita equivalence of [DiMa] involving Ariki–Koike algebras, see §3.4.

In Section 4, we show that the isomorphism of Theorem 3.4 can be chosen such that the shift automorphism of $H_n^\Lambda(q, \zeta)$ corresponds to a nice automorphism of $R_n^\Lambda(\Gamma)$. This automorphism is built from the automorphism of $\Gamma$ which maps a vertex $v = \zeta^i q^j$ for $(i, j) \in K := I \times J'$ to $\sigma(v) = \zeta v$. This explains why we chose the term “shift automorphism”. We finally deduce with Corollary 4.16 a cyclotomic quiver Hecke-like presentation for $H_{p,n}^\Lambda(q)$. In particular, this implies that $H_{p,n}^\Lambda(q)$ is a graded subalgebra of $H_{n}^\Lambda(q, \zeta)$ (Corollary 4.17) and that $H_{p,n}^\Lambda(q)$ does not depend on $q$ but on the quantum characteristic $e$ (Corollary 4.18).

Acknowledgements I am grateful to Maria Chlouveraki, Nicolas Jacon, Noah White and the referee for their numerous corrections. I also thank Andrew Mathas for his comments on a preliminary version of this paper, and Ivan Marin for discussions concerning the presentation of $G(r,p,n)$.

Notation Let $d, p, n \in \mathbb{N}^*$ with $n \geq 2$ and set $r := pd$. We work over a field $F$ that contains a primitive $p$th root of unity $\zeta$, in particular, the characteristic of $F$ does not divide $p$. We consider an element $q \in F \setminus \{0, 1\}$ and we write $e \in \mathbb{N}_{\geq 2} \cup \{\infty\}$ its order in $F^\times$. We define:

$$I := \begin{cases} \mathbb{Z}/e\mathbb{Z} & \text{if } e < \infty, \\ \mathbb{Z} & \text{otherwise } (e = \infty), \end{cases}$$

and $J := \mathbb{Z}/p\mathbb{Z} \simeq \langle \zeta \rangle$. 

3
1 The Hecke algebra of $G(r, p, n)$

Here we review two constructions of Ariki and Koike. Let $u = (u_1, \ldots, u_r)$ be a tuple of elements of $F^\times$.

1.1 The Hecke algebra of $G(r, 1, n)$

We recall here the definition of the cyclotomic Hecke algebra $H_n(u)$ of type $G(r, 1, n)$, also known as Ariki–Koike algebra.

**Definition 1.1 ([ArKo]).** The algebra $H_n(u)$ is the unitary associative $F$-algebra generated by the elements $S,T_1,\ldots,T_{n-1}$, subject to the following relations:

\[
\prod_{k=1}^{r} (S - u_k) = 0, 
\quad (T_a + 1)(T_a - q) = 0, 
\quad ST_1ST_1 = T_1ST_1S, 
\quad ST_a = T_aS \quad \text{if } a > 1, 
\quad T_aT_b = T_bT_a \quad \text{if } |a - b| > 1, 
\quad T_aT_{a+1}T_a = T_{a+1}T_aT_{a+1}.
\] (1.2a)-(1.2f)

According to [BMR], the algebra $H_n(u)$ is a Hecke algebra of the complex reflection group $G(r, 1, n)$. Let $X_1 := S$ and define for $a \in \{1, \ldots, n - 1\}$ the elements $X_{a+1} \in H_n(u)$ by:

\[qX_{a+1} := T_aX_aT_a.\] (1.3)

These elements $X_1, \ldots, X_n$ pairwise commute ([ArKo, Lemma 3.3.(2)]). Moreover, Matsumoto’s theorem (see, for instance, [GePf, Theorem 1.2.2]) ensures that (1.2c) and (1.2f) allow us to define $T_w := T_{a_1} \cdots T_{a_m}$ for any reduced expression $w = s_{a_1} \cdots s_{a_m} \in \mathfrak{S}_n$, where $s_a \in \mathfrak{S}_n$ is the transposition $(a, a + 1)$.

**Theorem 1.4 ([ArKo, Theorem 3.10]).** The elements

\[X_1^{m_1} \cdots X_n^{m_n}T_w\] (1.5)

for $m_1, \ldots, m_n \in \{0, \ldots, r - 1\}$ and $w \in \mathfrak{S}_n$ form a basis of the $F$-vector space $H_n(u)$.

Let $A = (A_{i,j}) \in \mathbb{N}^{(I \times J)}$ be a finitely-supported tuple of non-negative integers with $\sum_{i \in I} \sum_{j \in J} A_{i,j} = r$. We say that $A$ is a weight of level $r$. In particular, we can choose the parameters $u_1, \ldots, u_r$ such that the relation (1.2a) in $H_n(u)$ becomes the following one:

\[\prod_{i \in I} \prod_{j \in J} (S - \zeta^j q^i)^{A_{i,j}} = 0.\] (1.6)

**Definition 1.7.** In the above setting, we define $H_n^A(q, \zeta) := H_n(u)$.

We will often need the following condition on $A$:

\[A_{i,j} = A_{i,j'} := A_i \quad \text{for all } i \in I \text{ and } j, j' \in J.\] (1.8)

In this case, the weight $(A_i)_{i \in I}$ has level $d = \frac{r}{p}$. Moreover, we can write (1.6) as:

\[\prod_{i \in I} \prod_{j \in J} (S - \zeta^j q^i)^{A_i} = \prod_{i \in I} (S^p - q^{pi})^{A_i} = 0.\]

Thus, we get the following result.
Proposition 1.9. Suppose that $\Lambda$ satisfies (1.8). There is a well-defined algebra homomorphism $\sigma : \mathcal{H}_n(q, \zeta) \to \mathcal{H}_n^\Lambda(q, \zeta)$ given by:

$$
\begin{align*}
\sigma(S) & := \zeta S, \\
\sigma(T_a) & := T_a, \quad \text{for all } a \in \{1, \ldots, n-1\}.
\end{align*}
$$

Remark 1.10. The homomorphism $\sigma$ has order $p$, in particular $\sigma$ is bijective. We will refer to $\sigma$ as the shift automorphism of $\mathcal{H}_n^\Lambda(q, \zeta)$.

In the remaining part of this subsection, we assume that (1.8) is satisfied, so that the shift automorphism is defined. The following lemma is an easy induction.

Lemma 1.11. For every $a \in \{1, \ldots, n\}$ we have $\sigma(X_a) = \zeta X_a$.

Proposition 1.12. The elements of $\mathcal{H}_n^\Lambda(q, \zeta)$ fixed by $\sigma$ are exactly the elements in the $F$-span of $X_1^{m_1} \cdots X_n^{m_n} T_w$ for $m_1, \ldots, m_n \in \{0, \ldots, r-1\}$ and $w \in \mathfrak{S}_n$, with the additional following condition:

$$
m_1 + \cdots + m_n = 0 \pmod{p}.
$$

Proof. Let $h$ be an arbitrary element of $\mathcal{H}_n^\Lambda(q, \zeta)$. By Theorem 1.4, we can write, with $m = (m_a)_a$:

$$
h = \sum_{m \in \mathbb{N}^n, w \in \mathfrak{S}_n, 0 \leq m_a < r} h_{m,w} X_1^{m_1} \cdots X_n^{m_n} T_w,
$$

for some $h_{m,w} \in F$. Applying Lemma 1.11, we have:

$$
\sigma(h) = \sum_{m \in \mathbb{N}^n, w \in \mathfrak{S}_n, 0 \leq m_a < r} h_{m,w} \zeta^{m_1+\cdots+m_n} X_1^{m_1} \cdots X_n^{m_n} T_w,
$$

thus $\sigma(h) = h$ if and only if $\zeta^{m_1+\cdots+m_n} = 1$ when $h_{m,w} \neq 0$. We conclude since $\zeta$ is a primitive $p$th root of unity.

Note that the family in Proposition 1.12 is a basis, since it is free (by Theorem 1.4).

1.2 The Hecke algebra of $G(r, p, n)$

We continue to assume here that the weight $\Lambda$ satisfies the condition (1.8). In particular, for any $i \in I$ and $j \in J$ we have $\Lambda_{ij} = \Lambda_i$. We will first define the algebra that Ariki [Ar95] associated with $G(r, p, n)$, and then relate this algebra to §1.1.

Definition 1.13 ([Ar95]). We denote by $\mathcal{H}_{p,n}^\Lambda(q)$ the unitary associative $F$-algebra generated by $s, t_1, t_1', \ldots, t_{n-1}$, subject to the following relations:

$$
\prod_{i \in I} (s - q^a)^{\Lambda_i} = 0, \quad \text{(1.14a)}
$$

$$
(t_1' + 1)(t_1' - q) = (t_a + 1)(t_a - q) = 0, \quad \text{(1.14b)}
$$

$$
t_1't_2t_1' = t_2t_1t_2, \quad t_at_{a+1}t_a = t_{a+1}t_at_{a+1}, \quad \text{(1.14c)}
$$

$$
(t_1't_1t_1) = (t_1t_1t_1)^2, \quad \text{(1.14d)}
$$

$$
t_1't_0a = t_0a \Lambda' \quad \text{if } a \in \{3, \ldots, n-1\}, \quad \text{(1.14e)}
$$

$$
t_a t_b = t_b t_a \quad \text{if } |a - b| > 1, \quad \text{(1.14f)}
$$

$$
st_a = t_s \Lambda' \quad \text{if } a \in \{2, \ldots, n-1\}, \quad \text{(1.14g)}
$$

$$
\underline{s t_1' t_1 t_1' \ldots = t_1 st_1' t_1' \ldots} \quad \text{for } p+1 \text{ factors} \quad \underline{p+1 \text{ factors}} \quad \text{(1.14h)}
$$

According to [BMR], the algebra $\mathcal{H}_{p,n}^\Lambda(q)$ is a Hecke algebra of the complex reflection group $G(r, p, n)$.
Remark 1.15. We prove in §A.1 that the above presentation considered for \( p = 1 \) yields the Ariki–Koike algebra \( \mathcal{H}_n^A(q, 1) \) as defined in §1.1.

Remark 1.16. Assume here that \( p \geq 2 \). The reader may have noticed that the above presentation is not the one given by Ariki [Ar95]. Instead of (1.14i) Ariki gives the following relation:

\[
st'_1 t_1 = (q^{-1} t'_1 t_1)^{2-p} t_1 s'_1 t_1 + (q - 1) \sum_{k=1}^{p-2} (q^{-1} t'_1 t_1)^{1-k} s'_1.
\]

We claim that these two presentations define isomorphic algebras. Using (1.14b), we can show by induction the following equality:

\[
(q^{-1} t'_1 t_1)^{2-p} t_1 s'_1 + (q - 1) \sum_{k=1}^{p-2} (q^{-1} t'_1 t_1)^{1-k} s'_1 = (t'_1 t_1^{-1} t_1^{-1} t'_1^{-1} \cdots)(t_1 t'_1 t_1 t'_1) t_1 s'_1.
\]

Hence, using (1.14h) we get that (1.14i) and (1.14i') are equivalent, which proves the claim (we refer to §A.2 for more details). We conclude this remark by mentioning that the generators of [Ar95] are given by \( a_0 = s, a_1 = t'_1 \) and \( a_k = t_{k-1} \) for \( k \in \{2, \ldots, n\} \).

We state the main result of this section (note that the case \( p = 1 \) is proved by Theorems 1.14 and A.2).

**Theorem 1.17** ([Ar95, Proposition 1.6]). The algebra homomorphism \( \phi : \mathcal{H}^A_{p,n}(q) \to \mathcal{H}_n^A(q, \zeta) \) given by:

\[
\begin{align*}
\phi(s) & := S^p, \\
\phi(t'_1) & := S^{-1} T_1 S, \\
\phi(t_a) & := T_a, \quad \text{for all } a \in \{1, \ldots, n-1\}.
\end{align*}
\]

is well-defined and one-to-one. Moreover, the elements \( X_1^{m_1} \cdots X_n^{m_n} T_w \) of Theorem 1.4 such that \( m_1 + \cdots + m_n = 0 \) (mod \( p \)) form an \( F \)-basis of \( \phi(\mathcal{H}_{p,n}^A(q)) \).

In particular, using Proposition 1.12 we get the following one.

**Corollary 1.18.** The algebra \( \mathcal{H}_{p,n}^A(q) \) is isomorphic via \( \phi \) to \( \mathcal{H}_n^A(q, \zeta)^\sigma \), the fixed point subalgebra of \( \mathcal{H}_n^A(q, \zeta) \) under the shift automorphism \( \sigma \).

### 1.3 Removing repetitions

The following map:

\[
\begin{array}{ccc}
I \times J & \longrightarrow & F^X \\
(i, j) & \longmapsto & \zeta^j q^i
\end{array}
\]

is not one-to-one. The first aim of this subsection is to find a subset \( J' \subseteq \{1, \ldots, p\} \simeq J \) such that the restriction of the previous map to \( I \times J' \) has the same image and is one-to-one. Moreover, for our purposes, we would like relation (1.6) to be of the form:

\[
\prod_{i \in I, j \in J'} (S - \zeta^j q^i)^{\Lambda_{i,j}} = 0,
\]

(1.19)

where \( \Lambda = (\Lambda_{i,j})_{i \in I, j \in J'} \in \mathbb{N}^{(I \times J')} \) is a weight of level \( r \). The second aim of this subsection is to know for which tuples \( \Lambda \in \mathbb{N}^{(I \times J')^r} \) of level \( r \) there is some \( \Lambda \in \mathbb{N}^{(I \times J)} \) such that the relation (1.6) in \( \mathcal{H}_n^A(q, \zeta) \) is exactly (1.19). We will be particularly interested in the case where \( \Lambda \) satisfies (1.8). This will require some quite long but easy computations.

Let us define the following integer:

\[
p' := \min\{m \in \mathbb{N}^* : \zeta^m \in \langle q \rangle \} \in \{1, \ldots, p\},
\]

(1.20)

together with the following set:

\[
J' := \{1, \ldots, p'\}.
\]
Lemma 1.21. The integer $p'$ is given by:

- if $e = \infty$ then $p' = p$;
- if $e < \infty$ then $p' = \frac{p}{\gcd(p, e)}$.

In particular, the integer $p'$ divides $p$ and depends only on $p$ and $e$.

Proof. The statement for $e = \infty$ is obvious since each element of $\langle q \rangle \setminus \{1\}$ has infinite order. Thus, we now assume that $e < \infty$. For any $m \in \mathbb{N}^*$, the order of $\zeta^m$ in $F^\times$ is $\frac{p}{\gcd(p, m)}$. Since $q$ is a primitive $e$th root of unity, the set $\langle q \rangle$ is precisely the set of elements of $F^\times$ of order dividing $e$. Hence:

$$\zeta^m \in \langle q \rangle \iff \frac{p}{\gcd(p, m)} \text{ divides } e$$

$$\iff \frac{p}{\gcd(p, m)} \text{ divides } \gcd(p, e)$$

$$\iff \frac{p}{\gcd(p, e)} \text{ divides } \gcd(p, m).$$

We conclude that the minimal $m \in \mathbb{N}^*$ such that $\zeta^m \in \langle q \rangle$ is $p' = \frac{p}{\gcd(p, e)}$. \qed

The first aim of this subsection is achieved thanks to the next lemma, which is an immediate consequence of the minimality of $p'$.

Lemma 1.22. The elements $\zeta^iq^i$ for $i \in I$ and $j \in J'$ are pairwise distinct.

Let us denote by $\eta$ the (unique) element of $I$ such that:

$$\zeta^i = q^\eta. \quad (1.23)$$

Note that $p' = p \iff \eta = 0 \iff \langle q \rangle \cap \langle \zeta \rangle = \{1\}$. In particular, if $\eta \neq 0$ then $e < \infty$. In that case, we are not necessarily in the setting of [HuMa12] (see [Lemma 2.6.(a), loc. cit.]).

We now consider the following map:

$$J' \times \mathbb{Z}/\omega\mathbb{Z} \to I \quad \langle j, a \rangle \mapsto j + p'a, \quad (1.24)$$

where $\omega := \frac{p}{p'}$. It is well-defined and surjective, hence bijective by a counting argument. Equation (1.6) becomes:

$$\prod_{i \in I} \prod_{j \in J} (S - \zeta^iq^i)^{\Lambda_{i,j}} = \prod_{i \in I} \prod_{j \in J'} \prod_{a \in \mathbb{Z}/\omega\mathbb{Z}} (S - \zeta^j(q^i)^{\eta})^{\Lambda_{i,j} + p'a}$$

$$= \prod_{i \in I} \prod_{j \in J'} \prod_{a \in \mathbb{Z}/\omega\mathbb{Z}} (S - \zeta^j\eta^a)^{\Lambda_{i,j} + p'a}. \quad (1.25)$$

For each $(i, j) \in I \times J'$, we define:

$$\Lambda_{i,j} := \sum_{a \in \mathbb{Z}/\omega\mathbb{Z}} \sum_{i' + \eta a = i} \Lambda_{i', j + p'a}, \quad (1.26)$$

so that, by (1.25):

$$\prod_{i \in I} \prod_{j \in J} (S - \zeta^iq^i)^{\Lambda_{i,j}} = \prod_{i \in I} \prod_{j \in J'} (S - \zeta^jq^i)^{\Lambda_{i,j}}.$$

Hence, relation (1.6) transforms to the desired one (1.19). Conversely, it is clear that each weight $\Lambda \in \mathbb{N}^{(I \times J)}$ comes from some $\Lambda \in \mathbb{N}^{(I \times J')}$ through (1.26), that is, for each $\Lambda \in \mathbb{N}^{(I \times J')}$ there is some $\Lambda \in \mathbb{N}^{(I \times J)}$ such that (1.26) is satisfied. Indeed, given any $\Lambda \in \mathbb{N}^{(I \times J')}$ it suffices to set:

$$\Lambda_{i,j} := \begin{cases} \Lambda_{i,j} & \text{if } j \text{ is the image of } (j, 0) \text{ by the bijection of } (1.24), \\ 0 & \text{otherwise}, \end{cases}$$

for all $(i, j) \in I \times J$. 7
Definition 1.27. Let $\Lambda \in \mathbb{N}^{(I \times J)}$ be a weight of level $r$. We consider $\Lambda \in \mathbb{N}^{(I \times J)}$ a weight of level $r$ which gives $\Lambda$ through (1.26). We write $H_n^\Lambda(q, \zeta) := H_n^\Lambda(q, \zeta)$. In particular, the relation (1.6) becomes (1.19).

We now assume that the weight $\Lambda \in \mathbb{N}^{(I \times J)}$ satisfies the condition (1.8), that is, factors to $\Lambda \in \mathbb{N}^{(I)}$: we want to know which condition we recover on $\Lambda$. The defining equality (1.26) becomes:

$$\Lambda_{i,j} = \sum_{i' \in I} \sum_{a \in \mathbb{Z}/\omega \mathbb{Z}} \Lambda_{i',a} \eta a = i \Lambda_{i'},$$

for $i \in I$ and $j \in J'$. In particular, for any $i \in I$ and $j, j' \in J'$ we have $\Lambda_{i,j} = \Lambda_{i,j'} =: \Lambda_i$, so that $\Lambda \in \mathbb{N}^{(I)}$ is a weight of level $\omega d$, and:

$$\Lambda_i = \sum_{i' \in I} \sum_{a \in \mathbb{Z}/\omega \mathbb{Z}} \Lambda_{i',a},$$

(1.28)

for all $i \in I$.

Lemma 1.29. For any $i \in I$ we have:

$$\# \{a \in \mathbb{Z}/\omega \mathbb{Z} : \eta a = i\} = \begin{cases} 0 & \text{if } i \notin \eta I, \\ 1 & \text{if } i \in \eta I. \end{cases}$$

(1.30)

(1.31)

Proof. The result is straightforward if $\eta = 0$, in particular in that case we have $\omega = 1$. Thus we assume $\eta \neq 0$, in particular $e < \infty$ and $I = \mathbb{Z}/e\mathbb{Z}$. Let us compute the cardinality of the fibre of $i$ under the following group homomorphism:

$$\phi : \mathbb{Z} \rightarrow I, \quad a \mapsto \eta a.$$

First, the image of $\phi$ is $\eta I$; this proves (1.30). The element $\omega$ lies in ker $\phi$. Indeed, we have order($q^\eta$) = order($q^\eta$), hence:

$$\omega = \frac{e}{\gcd(e, \eta)},$$

(1.32)

thus $e = \gcd(e, \eta) \omega | \eta \omega$. As a consequence, we have a well-defined surjective map:

$$\overline{\phi} : \mathbb{Z}/\omega \mathbb{Z} \rightarrow \eta I, \quad a \mapsto \eta a.$$

We have, using (1.32):

$$\eta I = (\eta \mathbb{Z} + e\mathbb{Z})/e\mathbb{Z} \simeq \mathbb{Z}/\frac{\gcd(e, \eta)}{\gcd(e, \eta)} \mathbb{Z} = \mathbb{Z}/\omega \mathbb{Z},$$

thus, by a counting argument we get that the map $\overline{\phi}$ is bijective. This concludes the proof.

The second aim of this subsection is achieved thanks to the following proposition.

Proposition 1.33. A weight $\Lambda \in \mathbb{N}^{(I)}$ of level $\omega d$ comes from a weight $\Lambda \in \mathbb{N}^{(I)}$ of level $d$ through (1.28) if and only if for all $i \in I$,

$$\Lambda_i = \Lambda_{i,\eta},$$

that is, if and only if the weight $\Lambda$ factors to a weight $\Lambda \in \mathbb{N}^{(I/\eta I)}$ of level $d$.

Proof. First, by applying Lemma 1.29 to (1.28), we obtain the equivalent equality:

$$\Lambda_i = \sum_{i' \in I} \Lambda_{i',a} \eta a = \sum_{i' \in \eta I} \Lambda_{i',a},$$

(1.34)
for all $i \in I$. The necessary condition is hence straightforward. We now suppose that $\Lambda \in \mathbb{N}(I)$ factors to a weight $\Lambda \in \mathbb{N}(I/\eta I)$ of level $d$. For any $\gamma \in I/\eta I$, we choose any $\omega$ non-negative integers $\Lambda_i$ for $i \in \gamma$ such that $\sum_{i \in \gamma} \Lambda_i = \Lambda_\gamma$. We conclude that (1.34) and thus (1.26) hold since $\Lambda_i = \Lambda_\gamma$ if $i \in \gamma$.

**Definition 1.35.** We write $H^\Lambda_n(q, \zeta) := H^\Lambda_n(q, \zeta)$ and $H^\Lambda_{p,n}(q) := H^\Lambda_{p,n}(q)$ if $\Lambda \in \mathbb{N}(I)$ of level $\omega d$ and $\Lambda \in \mathbb{N}(I)$ of level $d$ are as in Proposition 1.33. In particular, the cyclotomic relation (1.6) in $H^\Lambda_n(q, \zeta)$ is:

$$\prod_{i \in I} \prod_{j \in J'} (S - \zeta^j q^i)^{\Lambda_i} = 0.$$ 

2 Cyclotomic quiver Hecke algebras

Let $K$ be a set and $\Gamma$ be a loop-free quiver without multiple (directed) edges, with vertex set $K$. For $k, k' \in K$:

- we write $k \not\rightarrow k'$ if neither $(k, k')$ nor $(k', k)$ is an edge of $\Gamma$;
- we write $k \rightarrow k'$ if $(k, k')$ is an edge of $\Gamma$ and $(k', k)$ is not;
- we write $k \leftarrow k'$ if $k' \rightarrow k$;
- we write $k \leftrightarrow k'$ if both $(k, k')$ and $(k', k)$ are edges of $\Gamma$.

If the next section we will define the (cyclotomic) quiver Hecke algebra associated with $\Gamma$. Furthermore, given an automorphism of this algebra built from an automorphism of the quiver, we will give a presentation of the fixed point subalgebra. Note that what follows has roughly the same outline as [Bo, BoMa].

2.1 Definition

Let $n \in \mathbb{N}^+$ and $\alpha = (\alpha_k)_{k \in K}$ be a (finitely supported) tuple of non-negative integers, whose sum is equal to $n$. We say that $\alpha$ is a $K$-composition of $n$ and we write $\alpha \models_K n$. Let $K^\alpha$ be the subset of $K^n$ consisting of the elements of $K^n$ which have, for any $k \in K$, exactly $\alpha_k$ components equal to $k$. The sets $K^\alpha$ are the $S_n$-orbits of $K^n$, in particular they are finite.

Following [KhLau1, KhLau2] and [Rou], we denote by $R_\alpha(\Gamma)$ the quiver Hecke algebra at $\alpha$ associated with $\Gamma$. It is the unitary associative $F$-algebra with generating set

$$\{e(k)\}_{k \in K^n} \cup \{y_1, \ldots, y_n\} \cup \{\psi_1, \ldots, \psi_{n-1}\}$$
The element $e(\alpha)$ is central and $\mathcal{R}_\alpha(\Gamma)e(\alpha) \simeq \mathcal{R}_\alpha(\Gamma)$. We have:

$$\mathcal{R}_\alpha(\Gamma) \simeq \bigoplus_{\alpha \models K^n} \mathcal{R}_\alpha(\Gamma),$$

and this isomorphism can be considered as a definition of $\mathcal{R}_\alpha(\Gamma)$ when $K$ is infinite (note that in that case, the algebra $\mathcal{R}_\alpha(\Gamma)$ is not unitary).
Now let $\mathbf{A} = (A_k)_{k \in K} \in \mathbb{N}^{(K)}$ be a finitely-supported tuple of non-negative integers. We define a particular case of cyclotomic quotient of $\mathcal{R}_{\alpha}(\Gamma)$ (see [KanKa] for the general case).

**Definition 2.4.** The cyclotomic quiver Hecke algebra $\mathcal{R}_{\alpha}^A(\Gamma)$ is the quotient of the quiver Hecke algebra $\mathcal{R}_{\alpha}(\Gamma)$ by the two-sided ideal $\mathcal{I}_{\alpha}^A$ generated by the following relations:

$$y_1^{A_k} e(k) = 0, \quad \text{for all } k \in K^\alpha. \quad (2.5)$$

Note that the grading on $\mathcal{R}_{\alpha}(\Gamma)$ gives a grading on $\mathcal{R}_{\alpha}^A(\Gamma)$. If $K$ is finite, the cyclotomic quotient $\mathcal{R}_{\alpha}^A(\Gamma)$ is obtained by quotienting $\mathcal{R}_{\alpha}(\Gamma)$ by the relations:

$$y_1^{A_k} e(k) = 0, \quad \text{for all } k \in K^\alpha.$$

Moreover, we have $e(\alpha)\mathcal{R}_{\alpha}^A(\Gamma) \cong \mathcal{R}_{\alpha}^A(\Gamma)$ and:

$$\mathcal{R}_{\alpha}^A(\Gamma) \cong \bigoplus_{\alpha | K} \mathcal{R}_{\alpha}^A(\Gamma),$$

and this can be considered as a definition of $\mathcal{R}_{\alpha}^A(\Gamma)$ if $K$ is infinite.

### 2.2 Properties of the underlying vector spaces

For each $w \in \mathfrak{S}_n$, we choose a reduced expression $w = s_{a_1} \cdots s_{a_r}$ and we set:

$$\psi_w := \psi_{a_1} \cdots \psi_{a_r} \in \mathcal{R}_{\alpha}(\Gamma). \quad (2.6)$$

Let $\alpha \models K_n$. We have the following theorem ([Rou, Theorem 3.7], [KhLau1, Theorem 2.5]).

**Theorem 2.7.** The family $\mathcal{B}_\alpha := \{\psi_w y_1^{m_1} \cdots y_n^{m_n} e(k) : w \in \mathfrak{S}_n, m_\alpha \in \mathbb{N}, k \in K^\alpha\}$ is a basis of the $F$-vector space $\mathcal{R}_{\alpha}(\Gamma)$.

Let $\mathbf{A} \in \mathbb{N}^{(K)}$ be a weight. It is not obvious that we can deduce a basis of the cyclotomic quiver Hecke algebra from the basis of Theorem 2.7. With this in mind, let us give the following lemma.

**Lemma 2.8** ([BrKl, Lemma 2.1]). The elements $y_a \in \mathcal{R}_{\alpha}^A(\Gamma)$ are nilpotent for any $a \in \{1, \ldots, n\}$.

**Remark 2.9.** The proof in [BrKl] is given for the quiver $\Gamma_e$. However, we can see immediately that their proof is valid for the quivers we use here.

We obtain the following theorem (see also [KanKa, §4.1]).

**Theorem 2.10.** The family:

$$\mathcal{B}_{\alpha}^A := \{\psi_w y_1^{m_1} \cdots y_n^{m_n} e(k) : w \in \mathfrak{S}_n, m_\alpha \in \mathbb{N}, k \in K^\alpha\},$$

is finite and spans $\mathcal{R}_{\alpha}^A(\Gamma)$ over $F$. In particular, the $F$-vector space $\mathcal{R}_{\alpha}^A(\Gamma)$ is finite-dimensional.

### 2.3 Fixed point subalgebra

Let $\sigma$ be an automorphism of $\Gamma$, that is:

- the map $\sigma : K \to K$ is a bijection;
- if $(k, k') \in K^2$ is an edge of $\Gamma$ then $\sigma(k), \sigma(k')) \in K^2$ is also an edge of $\Gamma$.

We assume that for any $p_1 \in \{1, \ldots, p-1\}$ and for any $k \in K$ we have $\sigma^{p_1}(k) \neq k = \sigma^p(k)$, in particular, we have $\sigma^p = \text{id}_K$.

**Remark 2.11.** Everything in this subsection §2.3 remains true if we only assume that $\sigma^p = \text{id}_K$: we just have to modify the sentence containing (2.22) and equalities (2.24), (2.41). Note that the automorphism involved in the proof of the main theorem (the automorphism which is defined in (4.8)) satisfies the above stronger condition.
Since $\sigma^p = \text{id}_K$, we have, for $k, k' \in K$:

$$(k, k') \in K^2 \text{ is an edge of } \Gamma \iff (\sigma(k), \sigma(k')) \in K^2 \text{ is an edge of } \Gamma,$$

thus we deduce the following lemma.

**Lemma 2.12.** Let $k, k' \in K$. We have:

$$k \rightarrow k' \iff \sigma(k) \rightarrow \sigma(k),$$

and there are similar equivalences for $\leftarrow, \sqsubseteq, =, \text{ and } \neq$.

The map $\sigma$ naturally induces a map $\sigma : K^n \rightarrow K^n$, defined by $\sigma(k) := (\sigma(k_1), \ldots, \sigma(k_n))$. For $\alpha \models_K n$, the following lemma explains how $\sigma : K^n \rightarrow K^n$ restricts to $K^\alpha$ (compare to [Bo, after Lemma 5.3.2]).

**Lemma 2.13.** For $\alpha \models_K n$, the map $\sigma : K^n \rightarrow K^n$ maps $K^n$ onto $K^\alpha$, where $\sigma \cdot \alpha$ is the $K$-composition of $n$ given by:

$$(\sigma \cdot \alpha)_k := \alpha_{\sigma^{-1}(k)}, \quad \text{for all } k \in K.$$

**Proof.** Let $k \in K^n$. We have:

- for all $k \in K$, $k$ has $\alpha_k$ components equal to $k$;
- $\iff$ for all $k \in K$, $\sigma(k)$ has $\alpha_k$ components equal to $\sigma(k)$;
- $\iff$ for all $k \in K$, $\sigma(k)$ has $\alpha_{\sigma^{-1}(k)}$ components equal to $k$;
- $\iff$ for all $k \in K$, $\sigma(k)$ has $(\sigma \cdot \alpha)_k$ components equal to $k$.

We conclude that $k \in K^\alpha \iff \sigma(k) \in K^{\alpha \cdot \alpha}$.

We can now explain how $\sigma$ induces an isomorphism between (cyclotomic) quiver Hecke algebras. We will also give a presentation for the fixed point subalgebras.

### 2.3.1 Affine case

In the affine case, we will be able to give a basis for the subalgebra of the fixed points of $\sigma$. As an easy consequence, we will give a presentation of this subalgebra.

**Theorem 2.14.** Let $\alpha \models_K n$. There is a well-defined algebra homomorphism $\sigma : \mathcal{R}_\alpha(\Gamma) \rightarrow \mathcal{R}_{\sigma \cdot \alpha}(\Gamma)$ given by:

$$
\begin{align*}
\sigma(e(k)) &:= e(\sigma(k)), & \text{for all } k \in K^n, \\
\sigma(y_a) &:= y_a, & \text{for all } a \in \{1, \ldots, n\}, \\
\sigma(\psi_a) &:= \psi_\alpha, & \text{for all } a \in \{1, \ldots, n - 1\}.
\end{align*}
$$

**Proof.** We check the different relations (2.1), thanks to Lemma 2.12 and the following fact:

$$\sigma(\kappa)_a = \sigma(k)_a,$$

for all $a \in \{1, \ldots, n\}$ and $k \in K^n$. Note that to prove (2.1a) we use the additional fact that $\sigma : K^n \rightarrow K^{\alpha \cdot \alpha}$ is a bijection.

**Remark 2.15.** By Lemma 2.12, the homomorphism $\sigma : \mathcal{R}_\alpha(\Gamma) \rightarrow \mathcal{R}_{\sigma \cdot \alpha}(\Gamma)$ is homogeneous with respect to the grading given in Proposition 2.2.

As in Section 1, we want to study the fixed points of $\sigma$. To that extent, we first need to find an algebra which is stable under $\sigma$. Let $[\alpha]$ be the orbit of $\alpha$ under the action of $\langle \sigma \rangle$. Note that since $\sigma^p = \text{id}_K$, the cardinality of $[\alpha]$ is at most $p$. For $\alpha \models_K n$ we define the following finite subset of $K^n$:

$$K^{[\alpha]} := \bigsqcup_{\beta \in [\alpha]} K^\beta,$$

(2.16)
and similarly we define the following unitary algebra:

\[ \mathcal{R}_{[\alpha]}(\Gamma) := \bigoplus_{\beta \in [\alpha]} \mathcal{R}_\beta(\Gamma). \]  

(2.17)

We obtain an automorphism \( \sigma : \mathcal{R}_{[\alpha]}(\Gamma) \rightarrow \mathcal{R}_{[\alpha]}(\Gamma) \).

Remark 2.18. We have \( \mathcal{R}_\alpha(\Gamma) \simeq \bigoplus_{[\alpha]} \mathcal{R}_{[\alpha]}(\Gamma) \), in particular, for \( k \in K^n \) the idempotent \( e(k) \) of \( \mathcal{R}_\alpha(\Gamma) \) belongs to \( \mathcal{R}_{[\alpha]}(\Gamma) \) if and only if \( k \in K^{[\alpha]} \).

We consider the equivalence relation \( \sim \) on \( K \) generated by:

\[ k \sim \sigma(k), \quad \text{for all } k \in K. \]  

(2.19)

We extend it to \( K^{[\alpha]} \) by:

\[ k \sim \sigma(k), \quad \text{for all } k \in K^{[\alpha]}. \]  

(2.20)

Definition 2.21. We write \( K^{[\alpha]}_\sigma \) for the quotient set \( K^{[\alpha]}/\sim \).

In particular, each element \( \gamma \in K^{[\alpha]}_\sigma \) has cardinality \( p \) and is of the form:

\[ \gamma = \{ k, \sigma(k), \ldots, \sigma^{p-1}(k) \}, \]  

(2.22)

with \( k \in K^{[\alpha]} \).

Definition 2.23. For \( \gamma \in K^{[\alpha]}_\sigma \), we define:

\[ e(\gamma) := \sum_{k \in K^{[\alpha]}_{\sim}} e(k). \]

These elements \( e(\gamma) \) have the property of being fixed by \( \sigma \). Note that for any \( k \in \gamma \), by (2.22) we have:

\[ e(\gamma) = \sum_{m=0}^{p-1} e(\sigma^m(k)). \]  

(2.24)

We now give the analogue of Proposition 1.12, by describing all the fixed points of \( \sigma \).

Theorem 2.25. The following family:

\[ \mathcal{B}^\sigma_{[\alpha]} := \{ \psi_w y_1 y_2 \cdots y_n e(\gamma) : w \in \mathfrak{S}_n, m_a \in \mathbb{N}, \gamma \in K^{[\alpha]}_\sigma \}, \]

is a \( F \)-basis of \( \mathcal{R}_{[\alpha]}(\Gamma)^\sigma \), the vector space of \( \sigma \)-fixed points of \( \mathcal{R}_{[\alpha]}(\Gamma) \).

Proof. First, by Theorem 2.7 we know that \( \mathcal{B}_{[\alpha]} := \bigcup_{\beta \in [\alpha]} \mathcal{B}_\beta \) is a linear basis of \( \mathcal{R}_{[\alpha]}(\Gamma) \). Hence, the family \( \mathcal{B}^\sigma_{[\alpha]} \) is linearly independent. Moreover, each element of \( \mathcal{B}^\sigma_{[\alpha]} \) is fixed by \( \sigma \). Now let \( h \in \mathcal{R}_{[\alpha]}(\Gamma) \) be fixed by \( \sigma \): we want to prove that \( h \) lies in \( \text{span}_F(\mathcal{B}^\sigma_{[\alpha]}) \). Using Theorem 2.7, we can write, with \( m = (m_a)_a \):

\[ h = \sum_{w \in \mathfrak{S}_n} \sum_{m \in \mathbb{N}^n} \sum_{k \in K^{[\alpha]}} h_{w,m,k} \psi_w y_1^{m_1} \cdots y_n^{m_n} e(k), \]

where \( h_{w,m,k} \in F \). We have:

\[ h = \sigma(h) = \sum_{w \in \mathfrak{S}_n} \sum_{m \in \mathbb{N}^n} \sum_{k \in K^{[\alpha]}} h_{w,m,k} \psi_w y_1^{m_1} \cdots y_n^{m_n} e(\sigma(k)), \]

and thus, since \( \mathcal{B}_{[\alpha]} \) is linearly independent:

\[ h_{w,m,k} = h_{w,m,\sigma(k)}, \]
for all $w \in \mathcal{S}_n$, $m \in \mathbb{N}^n$ and $k \in K^{[\alpha]}$. In particular, for each $\gamma \in K^{[\alpha]}_\sigma$ there is a well-defined scalar $h_{w,m,\gamma}$. We obtain:

\[
h = \sum_{w \in \mathcal{S}_n} \sum_{m \in \mathbb{N}^n} \sum_{\gamma \in K^{[\alpha]}_\sigma} h_{w,m,\gamma}\psi_w y_1^{m_1} \cdots y_n^{m_n} \sum_{k \in \gamma} e(k)
\]

\[
= \sum_{w \in \mathcal{S}_n} \sum_{m \in \mathbb{N}^n} \sum_{\gamma \in K^{[\alpha]}_\sigma} h_{w,m,\gamma}\psi_w y_1^{m_1} \cdots y_n^{m_n} e(\gamma),
\]

thus $h$ lies in $\text{span}_F(\mathcal{B}^{[\alpha]}_\sigma)$.

Theorem 2.25 allows us to give a presentation of the algebra $R^{[\alpha]}(\Gamma)^\sigma$. First, let us note that for any $a, b, c \in \{1, \ldots, n\}$ with $c < n$ and $\gamma \in K^{[\alpha]}_\sigma$, the expressions:

\[
s_c \cdot \gamma, \quad \gamma_a = \gamma_b, \quad \gamma_a \neq \gamma_b,
\]

\[
\gamma_a \rightarrow \gamma_b, \quad \gamma_a \leftarrow \gamma_b, \quad \gamma_a \equiv \gamma_b,
\]

are well-defined, thanks to Lemma 2.12.

Remark 2.26. In contrast, if $\gamma'$ is another element of $K^{[\alpha]}_\sigma$ then the expression $\gamma_a = \gamma_a'$ (for instance) is not well-defined. In particular, recalling (2.19) and (2.20), instead of subsets of $K^{[\alpha]}_\sigma = K^n/\sim$ we may want to consider subsets of $(K/\sim)^n$. This set $(K/\sim)^n$ has much worse properties. For instance, denoting by $k \in (K/\sim)^n$ the image of $k \in K^n$ (or $\gamma \in K^{[\alpha]}_\sigma$), if $\kappa_a = \kappa_{a+1}$ then we may have $h_a \neq h_{a+1}$ (or $\gamma_a \neq \gamma_{a+1}$).

Corollary 2.27. The algebra $R^{[\alpha]}(\Gamma)^\sigma$ has the following presentation. The generating set is:

\[
\{e(\gamma)\}_{\gamma \in K^{[\alpha]}_\sigma} \cup \{y_1, \ldots, y_n\} \cup \{\psi_1, \ldots, \psi_{n-1}\},
\]

and the relations are:

\[
\sum_{\gamma \in K^{[\alpha]}_\sigma} e(\gamma) = 1,
\]

\[
e(\gamma) e(\gamma') = \delta_{\gamma,\gamma'} e(\gamma),
\]

\[
y_a e(\gamma) = e(\gamma) y_a,
\]

\[
\psi_a e(\gamma) = e(s_a \cdot \gamma) \psi_a,
\]

\[
y_a y_b = y_b y_a,
\]

\[
\psi_a y_b = y_b \psi_a \quad \text{if} \quad b \neq a, a + 1,
\]

\[
\psi_a \psi_b = \psi_b \psi_a \quad \text{if} \quad |a - b| > 1,
\]

\[
\psi_a y_{a+1} e(\gamma) = \begin{cases} (y_a \psi_a + 1) e(\gamma) & \text{if} \quad \gamma_a = \gamma_{a+1}, \\ y_a \psi_a e(\gamma) & \text{if} \quad \gamma_a \neq \gamma_{a+1}, \end{cases}
\]

\[
y_{a+1} \psi_a e(\gamma) = \begin{cases} (\psi_a y_{a+1} + 1) e(\gamma) & \text{if} \quad \gamma_a = \gamma_{a+1}, \\ \psi_a y_{a+1} e(\gamma) & \text{if} \quad \gamma_a \neq \gamma_{a+1}, \end{cases}
\]

\[
\psi_a^2 e(\gamma) = \begin{cases} 0 & \text{if} \quad \gamma_a = \gamma_{a+1}, \\ e(\gamma) & \text{if} \quad \gamma_a \neq \gamma_{a+1}, \end{cases}
\]

\[
(y_{a+1} - y_a) e(\gamma) & \text{if} \quad \gamma_a \rightarrow \gamma_{a+1},
\]

\[
(y_a - y_{a+1}) e(\gamma) & \text{if} \quad \gamma_a \leftarrow \gamma_{a+1},
\]

\[
(y_{a+1} - y_a)(y_a - y_{a+1}) e(\gamma) & \text{if} \quad \gamma_a \equiv \gamma_{a+1},
\]

\[
\psi_{a+1} \psi_a \psi_{a+1} e(\gamma) = \begin{cases} (\psi_a \psi_{a+1} \psi_a - 1) e(\gamma) & \text{if} \quad \gamma_{a+2} = \gamma_a \rightarrow \gamma_{a+1}, \\ (\psi_a \psi_{a+1} \psi_a + 1) e(\gamma) & \text{if} \quad \gamma_{a+2} = \gamma_a \leftarrow \gamma_{a+1}, \\ (\psi_a \psi_{a+1} \psi_a + 2y_{a+1} - y_a - y_{a+2}) e(\gamma) & \text{if} \quad \gamma_{a+2} = \gamma_a \equiv \gamma_{a+1}, \\ \psi_a \psi_{a+1} \psi_a e(\gamma) & \text{otherwise}. \end{cases}
\]
Proof. Let us temporary write \( e(\gamma)^a, y_a^\sigma \) and \( \psi_a^\sigma \) for the generators of Corollary 2.27, and write \( R^\sigma \) for the algebra which admits this presentation. Given the defining relations (2.1) of \( R_{\alpha}(\Gamma) \) and Lemma 2.12, there is a well-defined algebra homomorphism \( f : R^\sigma \to R_{[\alpha]}(\Gamma) \) given by:

\[
f(e(\gamma)^a) := e(\gamma), \quad \text{for all } \gamma \in K_{[\alpha]}^\sigma, \\
f(y_a^\sigma) := y_a, \quad \text{for all } a \in \{1, \ldots, n\}, \\
f(\psi_a^\sigma) := \psi_a, \quad \text{for all } a \in \{1, \ldots, n-1\}.
\]

We can notice that the family:

\[
B^\sigma := \{ \psi_w(y_1)^{m_1} \cdots (y_n)^{m_n} e(\gamma)^\sigma : w \in S_n, m_a \in \mathbb{N}, \gamma \in K_{[\alpha]}^\sigma \},
\]

spans \( R^\sigma \) over \( F \), where the elements \( \psi_w \) are defined as in (2.6), with the same reduced expressions. We recall from Theorem 2.25 that the family

\[
B_{[\alpha]}^\sigma = \{ \psi_w y_1^{m_1} \cdots y_n^{m_n} e(\gamma) : w \in S_n, m_a \in \mathbb{N}, \gamma \in K_{[\alpha]}^\sigma \}
\]

is an \( F \)-basis of \( R_{[\alpha]}(\Gamma) \). Noticing that the algebra homomorphism \( f \) maps \( B^\sigma \) onto \( B_{[\alpha]}^\sigma \), we deduce that:

- the family \( B^\sigma \) is linearly independent;
- the map \( f \) surjects onto \( R_{[\alpha]}(\Gamma) \).

Finally, the family \( B^\sigma \) is a basis of \( R^\sigma \). In particular, the homomorphism \( f \) sends a basis to a basis hence \( f \) is an isomorphism. \(\square\)

The reader may have noticed the similarity between the relations (2.29) defining \( R_{[\alpha]}(\Gamma)^\sigma \) and the relations (2.1) defining \( R_{\alpha}(\Gamma) \). However, now the indexing set for the idempotents is generally not an \( S_n \)-stable subset of \( I^n \) for \( I \) an indexing set.

Remark 2.30. Since \( \sigma : R_{[\alpha]}(\Gamma) \to R_{[\alpha]}(\Gamma) \) is homogeneous (cf. Remark 2.15), the subalgebra \( R_{[\alpha]}(\Gamma)^\sigma \) is a graded subalgebra of \( R_{[\alpha]}(\Gamma) \). More precisely, as in Proposition 2.2 there is a unique \( \mathbb{Z} \)-grading on \( R_{[\alpha]}(\Gamma)^\sigma \) such that \( e(\gamma) \) is of degree 0, the element \( y_a \) is of degree 2 and \( \psi_a e(\gamma) \) is of degree \(-c_{[\alpha], a+1}\), where:

\[
c_{[\alpha], a+1} := \begin{cases} 2 & \text{if } \gamma_a = \gamma_a+1, \\ 0 & \text{if } \gamma_a \neq \gamma_a+1, \\ -1 & \text{if } \gamma_a \to \gamma_a+1 \text{ or } \gamma_a+1 \to \gamma_a, \\ -2 & \text{if } \gamma_a \equiv \gamma_a+1. \\ \end{cases}
\]

2.3.2 Cyclotomic case

Recall the Definition 2.4 of a cyclotomic quiver Hecke algebra. For \( \alpha \mid K \), \( n \), we want the algebra homomorphism \( \sigma : R_{\alpha}(\Gamma) \to R_{\alpha}(\Gamma) \) to factor through cyclotomic quotients. Contrary to the affine case, it will be more difficult to get a presentation for the fixed point subalgebra of the cyclotomic quiver Hecke algebra (recall that we do not have an analogue of Theorem 2.7). In particular, the whole proof relies on the map \( \mu \) which will be introduced in (2.37).

Let \( \Lambda \in \mathbb{N}^{(K)} \) be a weight. As for \( K \)-compositions, we define the weight \( \sigma \cdot \Lambda \in \mathbb{N}^{[K]} \) by:

\[
(\sigma \cdot \Lambda)_k := \Lambda_{\sigma^{-1}(k)}, \quad \text{for all } k \in K.
\]

Lemma 2.31. We have \( \sigma(I_{[\alpha]}^\Lambda) = I_{[\alpha]}^{\Lambda \sigma} \). In particular, the algebra homomorphism \( \sigma : R_{\alpha}(\Gamma) \to R_{\sigma(\alpha)}(\Gamma) \) induces an algebra homomorphism \( \sigma^\Lambda : R_{\alpha}(\Gamma) \to R_{\sigma(\alpha)}^{\Lambda}(\Gamma) \).

Proof. We notice that for \( k \in K^\alpha \) we have:

\[
\sigma(y_k^{\Lambda_k} e(\gamma)) = y_k^{\Lambda_k} e(\sigma(\gamma)) \in I_{[\alpha]}^{\Lambda \sigma},
\]

since \( A_k = (\sigma \cdot \Lambda)_{\sigma(\gamma)} \). Hence \( \sigma(I_{[\alpha]}^{\Lambda}) \subseteq I_{[\alpha]}^{\Lambda \sigma} \) and we have equality by repeating the argument with \( \sigma^{-1} \). \(\square\)
Until the end of this section, we make the following \( \sigma \)-stability assumption on our weight \( \Lambda \in \mathbb{N}^{|K|} \):

\[
\Lambda_k = \Lambda_{\sigma(k)}, \quad \text{for all } k \in K.
\]

(2.32)

that is, we assume that \( \Lambda = \sigma \cdot \Lambda \). Equivalently, the weight \( \Lambda \) factors to an element of \( \mathbb{N}^{|K|/\sim} \) (with the notation of (2.19)). The reader may have noticed the similarity with the equation of Proposition 1.33. In §4.2 we will explicitly make the link between these two assumptions.

Similarly to (2.17), we define:

\[
\mathcal{R}_{[\alpha]}^\Lambda(\Gamma) := \bigoplus_{\beta \in [\alpha]} \mathcal{R}_{\beta}^\Lambda(\Gamma).
\]

This algebra is the quotient of \( \mathcal{R}_{[\alpha]}(\Gamma) \) by the two sided ideal

\[
\mathcal{I}_{[\alpha]}^\Lambda := \bigoplus_{\beta \in [\alpha]} \mathcal{I}_{\beta}^\Lambda
\]

generated by the elements \( y_1^{\Lambda_1} e(k) \) for \( k \in K^{[\alpha]} \). We deduce from Lemma 2.31 the following statement.

**Lemma 2.33.** We have \( \sigma(\mathcal{I}_{[\alpha]}^\Lambda) = \mathcal{I}_{[\alpha]}^\Lambda \). Moreover, \( \sigma : \mathcal{R}_{[\alpha]}(\Gamma) \rightarrow \mathcal{R}_{[\alpha]}(\Gamma) \) induces an algebra homomorphism \( \sigma^\Lambda : \mathcal{R}_{[\beta]}^\Lambda(\Gamma) \rightarrow \mathcal{R}_{[\alpha]}^\Lambda(\Gamma) \).

If \( \pi_{[\alpha]} : \mathcal{R}_{[\alpha]}(\Gamma) \rightarrow \mathcal{R}_{[\alpha]}^\Lambda(\Gamma) \) is the canonical projection, by definition the induced automorphism \( \sigma^\Lambda \) satisfies:

\[
\sigma^\Lambda \circ \pi_{[\alpha]} = \pi_{[\alpha]} \circ \sigma.
\]

(2.34)

We will often write \( \sigma \) as well for the automorphism \( \sigma^\Lambda \).

**Definition 2.35.** We define \( \mathcal{R}_{[\alpha]}^\Lambda(\Gamma)^\sigma \) as the \( F \)-algebra of the fixed points of \( \mathcal{R}_{[\alpha]}^\Lambda(\Gamma) \) under the automorphism \( \sigma^\Lambda \).

We recall the notation of §2.3.1. Since \( \Lambda \) satisfies the \( \sigma \)-stability assumption (2.32) and considering the canonical map \( K^n = K^n/\sim \rightarrow (K/\sim)^n \), we may also consider the algebra \( (\mathcal{R}_{[\alpha]}(\Gamma)^\sigma)^\Lambda \), the quotient of \( \mathcal{R}_{[\alpha]}(\Gamma)^\sigma \) by the two-sided ideal \( \mathcal{I}_{[\alpha]}^\Lambda \) generated by the following relations:

\[
y_1^{\Lambda_1} e(\gamma) = 0, \quad \text{for all } \gamma \in K^{[\alpha]}.
\]

(2.36)

In order to give a presentation of \( \mathcal{R}_{[\alpha]}^\Lambda(\Gamma)^\sigma \), we want to prove that this algebra is isomorphic to the following one:

\[
(\mathcal{R}_{[\alpha]}(\Gamma)^\sigma)^\Lambda = \mathcal{R}_{[\alpha]}(\Gamma)^\sigma / \mathcal{I}_{[\alpha], \sigma}^\Lambda,
\]

for which we know a presentation. Recalling that the characteristic of \( F \) does not divide \( p \), we can define the following linear map:

\[
\mu : \begin{array}{ccc}
\mathcal{R}_{[\alpha]}(\Gamma) & \rightarrow & \mathcal{R}_{[\alpha]}(\Gamma) \\
h & \mapsto & \frac{1}{p} \sum_{m=0}^{p-1} \sigma^m(h).
\end{array}
\]

(2.37)

We now give a succession of lemmas involving this map \( \mu \).

**Lemma 2.38.** The following properties are satisfied by the linear map \( \mu \):

\[
\mu(\mathcal{R}_{[\alpha]}(\Gamma)) = \mathcal{R}_{[\alpha]}(\Gamma)^\sigma,
\]

\[
\mu(h) = h, \quad \text{for all } h \in \mathcal{R}_{[\alpha]}(\Gamma)^\sigma.
\]

Moreover, we have:

\[
\mu(\mathcal{I}_{[\alpha]}^\Lambda) = \mathcal{I}_{[\alpha]}^\Lambda \cap \mathcal{R}_{[\alpha]}(\Gamma)^\sigma.
\]

**Proof.** The first two statements follow from \( \sigma^p = \text{id} \). We deduce the last one using Lemma 2.33. \( \square \)
Remark 2.39. The linear map $\mu$ is a linear projection onto the subspace $R_{[0]}(\Gamma)$. 

Lemma 2.40. We have the following equality:

$$T^\Lambda_{[0]} \cap R_{[0]}(\Gamma) = T^\Lambda_{[0],\sigma}.$$ 

In particular, $\mu(T^\Lambda_{[0]}) = T^\Lambda_{[0],\sigma}$. 

Proof. Since for $\gamma \in K_{[0]}(\sigma)$ we have $y_1^{\Lambda_{\gamma}} e(\gamma) \in T^\Lambda_{[0]} \cap R_{[0]}(\Gamma)$, we get $T^\Lambda_{[0]} \cap R_{[0]}(\Gamma) \subseteq T^\Lambda_{[0],\sigma}$. We now consider an element $h$ of $T^\Lambda_{[0]}$. Because of (2.1a), (2.1b) and Theorem 2.10, we know that we have:

$$h = \sum_{w_1, w_2 \in \Theta, m, \sigma} h_{k} \psi_{w_1} y_1^{\lambda_{w_1}} \cdots y_{\sigma}^{\lambda_{w_2}} \left[y_1^{\lambda_{w_1}} e(\sigma_{w_2})\right] \psi_{w_2} y_1^{\sigma_{w_2}} \cdots y_{\sigma}^{\sigma_{w_2}},$$

where the $h_{k} \in F$ are some scalars which depend on $k$ and on the other various indices of the sums. For $m = 0, \ldots, p - 1$ we have:

$$\sigma^{m}(h) = \sum_{w_1, w_2 \in \Theta, m, \sigma} h_{k} \psi_{w_1} y_1^{\lambda_{w_1}} \cdots y_{\sigma}^{\lambda_{w_2}} \left[y_1^{\lambda_{w_1}} e(\sigma_{w_2})\right] \psi_{w_2} y_1^{\sigma_{w_2}} \cdots y_{\sigma}^{\sigma_{w_2}}.$$

Summing all these equalities from $m = 0$ to $p - 1$ and using (2.24) we get, where $\gamma_{k} \in K_{[0]}$ is such that $k \in \gamma_{k}$:

$$p\mu(h) = \sum_{w_1, w_2 \in \Theta, m, \sigma} h_{k} \psi_{w_1} y_1^{\lambda_{w_1}} \cdots y_{\sigma}^{\lambda_{w_2}} \left[y_1^{\lambda_{w_1}} e(\gamma_{k})\right] \psi_{w_2} y_1^{\sigma_{w_2}} \cdots y_{\sigma}^{\sigma_{w_2}}.$$  

(2.41)

Since:

- we have $p \neq 0$;
- the elements $\psi_{w_1} y_1^{\lambda_{w_1}} \cdots y_{\sigma}^{\lambda_{w_2}} e(\gamma_{k})$ and $e(\gamma_{k}) \psi_{w_2} y_1^{\sigma_{w_2}} \cdots y_{\sigma}^{\sigma_{w_2}}$ belong to $R_{[0]}(\Gamma)$;
- with $\gamma = \gamma_{k}$ we have $\Lambda_{\gamma} = \Lambda_{k}$ (recall (2.32));

we deduce that $\mu(h) \in T^\Lambda_{[0],\sigma}$. Hence, if in addition $h \in R_{[0]}(\Gamma)$ then we have $\mu(h) = h$ thus we conclude that $T^\Lambda_{[0]} \cap R_{[0]}(\Gamma) \subseteq T^\Lambda_{[0],\sigma}$. Finally, we get $T^\Lambda_{[0]} \cap R_{[0]}(\Gamma) = T^\Lambda_{[0],\sigma}$, and we deduce the last statement from Lemma 2.38.

Lemma 2.42. For each $h \in R^\Lambda_{[0]}(\Gamma)$, there is some $h \in R_{[0]}(\Gamma)$ such that $\pi_{[0]}(h) = h$.

Proof. Let $h \in R^\Lambda_{[0]}(\Gamma)$ and let $h_0 \in R_{[0]}(\Gamma)$ be such that $\pi_{[0]}(h_0) = h$. Since $h$ is fixed by $\sigma^\Lambda$, we have $\sigma(h_0) - h_0 \in T^\Lambda_{[0]}$. Hence, by Lemma 2.33 we obtain:

$$\sigma^{m+1}(h_0) - \sigma^{m}(h_0) \in T^\Lambda_{[0]},$$

thus, by summing:

$$\sigma^{m}(h_0) - h_0 \in T^\Lambda_{[0]},$$

for all $m \in \{0, \ldots, p - 1\}$ (note that this is trivial for $m = 0$). Setting $h := \mu(h_0)$ we get $h - h_0 \in T^\Lambda_{[0]}$ thus $\pi_{[0]}(h) = \pi_{[0]}(h_0) = h$. We conclude since by Lemma 2.38 we have $h \in R_{[0]}(\Gamma)$. 

We are now ready to state the main theorem of this section. We recall that the idempotents $\{e(\gamma)\}_{\gamma}$ of (2.28) are indexed by the set $K_{[0]}$, which is defined in Definition 2.21.

Theorem 2.43. The algebras $R^\Lambda_{[0]}(\Gamma)$ and $(R_{[0]}(\Gamma))^\Lambda$ are isomorphic. In particular, the generators (2.28) together with the relations (2.29) and (2.36) give a presentation of $R^\Lambda_{[0]}(\Gamma)$. 

17
Proof. Recalling Corollary 2.27, we begin by noticing that the given presentation is a presentation of \((\mathcal{R}_{[\alpha]}(\Gamma)^{\sigma})^{\Lambda}\). In particular, we can define a homomorphism of algebras \(f : (\mathcal{R}_{[\alpha]}(\Gamma)^{\sigma})^{\Lambda} \to \mathcal{R}_{[\alpha]}^{\Lambda}(\Gamma)^{\sigma}\) by:

\[
  f(e(\gamma)) := e(\gamma), \quad \text{for all } \gamma \in K_{[\alpha]}^{[n]}, \\
f(y_a) := y_a, \quad \text{for all } a \in \{1, \ldots, n\}, \\
f(\psi_a) := \psi_a, \quad \text{for all } a \in \{1, \ldots, n - 1\}.
\]

If \(\pi^{\sigma}_{[\alpha]} : \mathcal{R}_{[\alpha]}(\Gamma)^{\sigma} \to (\mathcal{R}_{[\alpha]}(\Gamma)^{\sigma})^{\Lambda}\) is the canonical projection, we have:

\[
f \circ \pi^{\sigma}_{[\alpha]}(h) = \pi^{\sigma}_{[\alpha]}(h) \quad (2.44)
\]

for all \(h \in \mathcal{R}_{[\alpha]}(\Gamma)^{\sigma}\) (it suffices to check this equality for each generator of \(\mathcal{R}_{[\alpha]}(\Gamma)^{\sigma}\)). We now want to construct an inverse \(\mathcal{R}_{[\alpha]}^{\Lambda}(\Gamma)^{\sigma} \to (\mathcal{R}_{[\alpha]}(\Gamma)^{\sigma})^{\Lambda}\) given by \(\mu_1 = \pi^{\sigma}_{[\alpha]} \circ \mu\). By Lemma 2.40, we have \(\ker \mu_1 \supseteq \mathcal{I}_{[\alpha]}\), hence we have a well-defined linear map:

\[
\mu_2 : \mathcal{R}_{[\alpha]}^{\Lambda}(\Gamma) \to (\mathcal{R}_{[\alpha]}(\Gamma)^{\sigma})^{\Lambda},
\]

and by restriction we get a linear map \(\overline{\mu} : \mathcal{R}_{[\alpha]}^{\Lambda}(\Gamma)^{\sigma} \to (\mathcal{R}_{[\alpha]}(\Gamma)^{\sigma})^{\Lambda}\). To summarise, we have a commutative diagram (2.45).

\[
\begin{array}{ccc}
\mathcal{R}_{[\alpha]}(\Gamma) & \xrightarrow{\mu} & \mathcal{R}_{[\alpha]}(\Gamma)^{\sigma} \\
\downarrow{\pi^{\sigma}_{[\alpha]}} & & \downarrow{\pi^{\sigma}_{[\alpha]}} \\
\mathcal{R}_{[\alpha]}^{\Lambda}(\Gamma) & \xrightarrow{\mu_2} & (\mathcal{R}_{[\alpha]}(\Gamma)^{\sigma})^{\Lambda} \\
\downarrow{\overline{\mu}} & & \downarrow{\overline{\mu}} \\
\mathcal{R}_{[\alpha]}^{\Lambda}(\Gamma)^{\sigma} & & \\
\end{array}
\]

Let \(h \in \mathcal{R}_{[\alpha]}(\Gamma)^{\sigma}\). We want to prove the following equality:

\[
\overline{\mu} \circ \pi^{\sigma}_{[\alpha]}(h) = \pi^{\sigma}_{[\alpha]}(h). \quad (2.46)
\]

First, by (2.34) we have \(\pi^{\sigma}_{[\alpha]}(h) \in \mathcal{R}_{[\alpha]}^{\Lambda}(\Gamma)^{\sigma}\) hence we can evaluate \(\overline{\mu}\) at \(\pi^{\sigma}_{[\alpha]}(h)\). We now use the commutative diagram (2.45):

\[
\overline{\mu} \circ \pi^{\sigma}_{[\alpha]}(h) = \mu_2 \circ \pi^{\sigma}_{[\alpha]}(h) = \mu_1(h) = \pi^{\sigma}_{[\alpha]} \circ \mu(h),
\]

and we conclude since \(\mu(h) = h\) by Lemma 2.38.

Finally, let us prove that \(f\) and \(\overline{\mu}\) are mutual inverses.

- Let \(h \in (\mathcal{R}_{[\alpha]}(\Gamma)^{\sigma})^{\Lambda}\). If \(h \in \mathcal{R}_{[\alpha]}(\Gamma)^{\sigma}\) is such that \(\pi^{\sigma}_{[\alpha]}(h) = h\), we have, using (2.44) and (2.46):

\[
\overline{\mu} \circ f(h) = \overline{\mu} \circ f \circ \pi^{\sigma}_{[\alpha]}(h) = \overline{\mu} \circ \pi^{\sigma}_{[\alpha]}(h) = \pi^{\sigma}_{[\alpha]}(h) = h,
\]

hence \(\overline{\mu} \circ f\) is the identity of \((\mathcal{R}_{[\alpha]}(\Gamma)^{\sigma})^{\Lambda}\).

- Let \(h \in \mathcal{R}_{[\alpha]}^{\Lambda}(\Gamma)^{\sigma}\). By Lemma 2.42, we can find \(h \in \mathcal{R}_{[\alpha]}(\Gamma)^{\sigma}\) such that \(\pi^{\sigma}_{[\alpha]}(h) = h\). Using once again (2.44) and (2.46) we get:

\[
f \circ \overline{\mu}(h) = f \circ \overline{\mu} \circ \pi^{\sigma}_{[\alpha]}(h) = f \circ \pi^{\sigma}_{[\alpha]}(h) = \pi^{\sigma}_{[\alpha]}(h) = h,
\]

thus \(f \circ \overline{\mu}\) is the identity of \(\mathcal{R}_{[\alpha]}^{\Lambda}(\Gamma)^{\sigma}\).
In particular, the algebra homomorphism \( f \) is bijective, hence is an algebra isomorphism between \( R_{[\alpha]}(\Gamma)^\sigma \) and \( (R_{[\alpha]}(\Gamma)\sigma)^\Lambda \).

**Remark 2.47.** The grading of Remark 2.30 thus gives a grading on \( R_{[\alpha]}(\Gamma)^\sigma \), for which \( \sigma^\Lambda \) is homogeneous (recall Remark 2.15). Moreover, the algebra \( R_{[\alpha]}(\Gamma)^\sigma \) is a graded subalgebra of \( R_{[\alpha]}(\Gamma) \).

### 3 The isomorphism of Brundan and Kleshchev

In this section, we generalise an isomorphism of Brundan and Kleshchev \([BrKl]\) involving \( H_n(q, \zeta) \) to the case of the algebra \( H_n(q, 1) \).

#### 3.1 Statement

We consider the quiver \( \Gamma_e \) defined as follows:

- the vertex set is \( \{q^j\}_{i \in I} \);
- there is a directed edge from \( v \) to \( qv \) for each vertex \( v \) of \( \Gamma_e \).

We will often identify the vertex set with \( I \) in the canonical way. In particular, if \( i \) is a vertex then there is a directed arrow from \( i \) to \( i + 1 \). For \( i, i' \in I \), with the notation of Section 2 we thus have:

\[
\begin{align*}
  i \to i' & \iff [i' = i + 1 \text{ and } i \neq i' + 1], \\
  i \leftarrow i' & \iff [i = i' + 1 \text{ and } i' \neq i + 1], \\
  i \leftrightarrow i' & \iff [i = i' + 1 \text{ and } i' = i + 1], \\
  i \not\rightarrow i' & \iff i \neq i', i' \pm 1.
\end{align*}
\]

The quiver \( \Gamma_e \) is the cyclic quiver with \( e \) vertices if \( e < \infty \), and a two-sided infinite line if \( e = \infty \): we give some examples in Figure 1, where we used the identification between the vertex set of \( \Gamma_e \) and \( I \).

![Figure 1: Three examples of quivers \( \Gamma_e \) ](image)

We recall the notation \( p' \) and \( J' \) introduced at §1.3. We set \( K := I \times J' \). Let us consider \( p' \) non-zero elements \( v_1, \ldots, v_{p'} \) of \( F \) which lie in distinct orbits under the action of \( \langle q \rangle \) on \( F^\times \), that is, for any \( k \neq l \) we have:

\[
\frac{v_k}{v_l} \notin \langle q \rangle. \quad (3.1)
\]

We then consider the quiver \( \Gamma \) defined as follows:

- the vertex set is \( V := \{v_jq^j\}_{i \in I, j \in J'} \);
- there is a directed edge from \( v \) to \( qv \) for each vertex \( v \) of \( \Gamma \).
Since the $v_k$ lie in different $q$-orbits, the vertex set $V$ of $\Gamma$ can be identified with $K = I \times J'$. More precisely, we have the following decomposition:

$$V = \bigsqcup_{j \in J'} \{v_jq^i\}_{i \in I}. \tag{3.2}$$

Since:
- the subquiver of $\Gamma$ with vertex set $\{v_jq^i\}_{i \in I}$ is a copy of $\Gamma_e$;
- for $j \neq j' \in J'$, there is no arrow between any element of $\{v_jq^i\}_{i \in I}$ and $\{v_j'q^i\}_{i \in I}$;
- the set $J'$ has cardinality $p'$;
we conclude from (3.2) that $\Gamma$ is exactly $p'$ disjoint copies of $\Gamma_e$. In particular, the quiver $\Gamma$ is loop-free and has no multiple edges.

As a consequence, we will often write $(i, j) \in I \times J'$ for the vertex $v_jq^i \in V$ of $\Gamma$. For any $i, i' \in I$ and $j, j' \in J'$, what precedes ensures that the vertices $(i, j)$ and $(i', j')$ are in the same copy of $\Gamma_e$ if and only if $j = j'$. Further, there is a directed edge from $(i, j)$ to $(i', j')$ if and only if $j = j'$ and there is a directed edge in $\Gamma_e$ from $i$ to $i'$. We give some examples of quivers $\Gamma$ in Figure 2, where, for aesthetic reasons, we write $i_j$ instead of $v_jq^i$. We also recall from Lemma 1.21 that $p' = \frac{p}{\gcd(p, e)}$ if $e < \infty$ and $p' = p$ if $e = \infty$.

Case $(e, p) = (2, 3)$

$$\begin{align*}
0_1 & \rightarrow 1_1 \\
0_2 & \rightarrow 1_2 \\
0_3 & \rightarrow 1_3
\end{align*} \quad \text{Figure 2: Three examples of quivers $\Gamma$}$$

Case $(e, p) = (2, 6)$

$$\begin{align*}
\cdots & \rightarrow -2_1 \rightarrow -1_1 \rightarrow 0_1 \rightarrow 1_1 \rightarrow 2_1 \rightarrow \cdots
\end{align*}$$

Case $(e, p) = (\infty, 2)$

$$\begin{align*}
\cdots & \rightarrow -2_2 \rightarrow -1_2 \rightarrow 0_2 \rightarrow 1_2 \rightarrow 2_2 \rightarrow \cdots
\end{align*}$$

Now let $\Lambda = (\Lambda_k)_{k \in K} \in \mathbb{N}^{(K)}$ be a weight of level $r$. Mimicking the definition of $H_n^{\Lambda}(q, \zeta)$, let us choose a tuple $u \in (\mathbb{F}^\times)^r$ which is given by exactly $\Lambda_{i,j}$ copies of $v_jq^i$ for each $(i, j) \in I \times J'$ and set $H_n^{\Lambda}(q, v) := H_n(u)$. As a result, the relation (1.2a) in $H_n(u)$ is:

$$\prod_{i \in I} \prod_{j \in J'} (S - v_jq^i)^{\Lambda_{i,j}} = 0. \tag{3.3}$$

The remaining part of this section is devoted to the proof of the following theorem.

**Theorem 3.4.** There is an explicit $F$-algebra isomorphism:

$$H_n^{\Lambda}(q, v) \simeq R_n^{\Lambda}(\Gamma).$$

Brundan and Kleshchev [BrKl] proved Theorem 3.4 for $p = 1$: in that case, we have $p' = 1$, the tuple $v$ has only one component (that can be taken equal to 1) and $\Gamma = \Gamma_e$. We will see that the same argument proves the general case. Such an isomorphism, for $e < \infty$, was already obtained by Rouquier [Rou, Corollary 3.20].

### 3.2 Candidate homomorphisms

We recall that $V \simeq K = I \times J'$, together with the definitions $X_1 := S$ and $qX_{a+1} := \alpha a X_a T_a$ from (1.3). To prove Theorem 3.4, it suffices to give an isomorphism between $H_n^{\Lambda}(q, v)$ (see (3.7)) and $R_n^{\Lambda}(\Gamma)$ for any $\alpha \vdash_K n$. Let $M$ be a finite-dimensional $H_n^{\Lambda}(q, v)$-module.

**Lemma 3.5.** For any $a \in \{1, \ldots, n\}$, the eigenvalues of $X_a$ on $M$ are of the form $v_jq^i$ for $i \in I$ and $j \in J'$. 

20
Proof. The statement is of course true for \( a = 1 \) by (1.6). By induction, using [ArKo] or [Gr, Lemma 4.7] we know that any eigenvalue of \( X_{a+1} \) differs from an eigenvalues of \( X_a \) by a power of \( q \).

Hence, as the elements \( X_1, \ldots, X_n \) pairwise commute, we can write \( M \) as a direct sum of generalised simultaneous eigenspaces:

\[
M = \bigoplus_{k \in K^n} M(k),
\]

where \( M(k) = M(i, j) \) is defined by, for \( k = (i, j) \in K^n \approx I^n \times J^n \):

\[
M(i, j) := \left\{ m \in M : (X_a - v_a q^{i_a})^N m = 0 \text{ for all } 1 \leq a \leq n \right\},
\]

where \( N \gg 0 \). Note that all but finitely many \( M(k) \) are reduced to \( \{0\} \). We now consider the family \( \{e(k)\}_{k \in K^n} \) of projections associated with the decomposition above. In particular:

- we have \( e(k)e(k') = \delta_{k,k'}e(k) \);
- we have \( \sum_{k \in K^n} e(k) = \text{id} \) (this is a finite sum since all but finitely many \( e(k) \) are zero);
- we have \( e(k)M = M(k) \).

Remark 3.6. We already used the notation \( e(k) \) for some generators of \( R^\Lambda_n (\Gamma) \). This abuse of notation will be justified by the proof of Theorem 3.4, where we prove that these elements can be identified.

Since \( e(k) \) is a polynomial in \( X_1, \ldots, X_n \) we have \( e(k) \in H^\Lambda_n (q, v) \). If now \( \alpha \models K \) is a \( K \)-composition of \( n \), the following element:

\[
e(\alpha) := \sum_{k \in K^n} e(k) \in H^\Lambda_n (q, v),
\]

is a central idempotent (the reader should compare this definition to (2.3)). We thus get a subalgebra:

\[
H^\Lambda_n (q, v) := e(\alpha)H^\Lambda_n (q, v). \tag{3.7}
\]

Remark 3.8. The subalgebra \( H^\Lambda_n (q, v) \) is either \( \{0\} \) or a block of \( H^\Lambda_n (q, v) \) (see [LyMa]). This block has unit \( e(\alpha) \).

Recall that the elements \( y_a \in R^\Lambda_n (\Gamma) \) for \( 1 \leq a \leq n \) are nilpotent (Lemma 2.8). Hence, each power series \( f(y_1, \ldots, y_n) \in F[[y_1, \ldots, y_n]] \) in these elements is a well-defined element of \( R^\Lambda_n (\Gamma) \). In particular, for \( a \in \{1, \ldots, n-1\} \) and \( k \in K^n \) the following power series is well-defined in \( R^\Lambda_n (\Gamma) \):

\[
P_a(k) := \begin{cases} 1 & \text{if } k_a = k_{a+1}, \\ (1 - q)(1 - y_a(k)y_{a+1}(k))^{-1} & \text{if } k_a \neq k_{a+1}, \end{cases} \tag{3.9}
\]

where:

\[
y_a(k) := v_{a j} q^{i_j} (1 - y_a) \text{ if } k = (i, j). \tag{3.10}
\]

For \( k = (i, j) \in K = I \times J' \), we define:

\[
q^k := q^i, \quad q^{-k} := q^{-i}, \\
v_k := v_{ij}, \quad v_{-k} := v_{ij}^{-1}, \tag{3.11}
\]

in particular we obtain \( y_a(k) = v_{a j} q^{i_j} (1 - y_a) \) for any \( k \in K^n \). Note that:

\[
1 - y_a(k)y_{a+1}(k)^{-1} = \frac{y_{a+1}(k) - y_a(k)}{y_{a+1}(k)} = \frac{(q_{a+1} q^{k_{a+1}} - v_{a j} q^{i_j}) + v_{a j} q^{i_j} y_a - v_{a+1} q^{k_{a+1}} y_{a+1}}{y_{a+1}(k)}.
\]
thus, by (3.1) we know that this expression is indeed invertible when $k_a \neq k_{a+1}$.

For $(w, f) \in \mathcal{S}_n \times F[[y_1, \ldots, y_n]]$, we denote by $f^w \in F[[y_1, \ldots, y_n]]$ the usual right action of $w$ on $f$. For instance, if $w = \tau$ is a transposition then $f^\tau(y_1, \ldots, y_n) = f(y_{\tau(1)}, \ldots, y_{\tau(n)})$.

Let us give a lemma involving this action (see, for instance, [BrKl, (2.6)])..

**Lemma 3.12.** For any $f \in F[[y_1, \ldots, y_n]], a \in \{1, \ldots, n-1\}$ and $k \in K^\alpha$ we have:

$$f^w f^a e(k) = \begin{cases} \psi a f^a e(k) + \partial_a(f) e(k) & \text{if } k_a = k_{a+1}, \\ \psi a f^a e(k) & \text{if } k_a \neq k_{a+1}, \end{cases}$$

where $\partial_a(f) := \frac{f^a - f}{y_a - y_{a+1}} \in F[[y_1, \ldots, y_n]].$

**Proof.** This is a consequence of (2.1f), (2.1h) and (2.1).

We say that a family $\{Q_a(k)\}_{a \in \{1, \ldots, n-1\}} \in K^\alpha$ of elements of $F[[y_1, \ldots, y_n]]$ satisfies the property (BK) if:

$$Q_a(k)$$

is an invertible element of $F[[y_a, y_{a+1}]],$ 

$$Q_a(k) = 1 - q + q y_{a+1} - y_a \quad \text{if } k_a = k_{a+1},$$

$$Q_a(k)Q_a(s_a \cdot k)^{s_a} = \begin{cases} (1 - P_a(k))(q + P_a(k)) & \text{if } k_a \neq k_{a+1}, \\ (1 - P_a(k))(q + P_a(k)) & \text{if } k_a \rightarrow k_{a+1}, \\ y_{a+1} - y_a & \text{if } k_a \leftarrow k_{a+1}, \\ (1 - P_a(k))(q + P_a(k)) & \text{if } k_a \equiv k_{a+1}, \end{cases}$$

$$(s_a + 1)Q_a(s_a \cdot k)^{s_a} = Q_a(s_a s_{a+1} \cdot k)^{s_{a+1}}.$$ (3.16)

We can now give the key of Theorem 3.4.

**Theorem 3.17.** Let $\{Q_a(k)\}_{a \in \{1, \ldots, n-1\}} \in K^\alpha$ be a family of elements of $F[[y_1, \ldots, y_n]]$ which satisfies (BK). There exist unique $F$-algebra homomorphisms $f : H^\alpha_v(q, \psi) \rightarrow R^\alpha_v(\Gamma)$ and $g : R^\alpha_v(\Gamma) \rightarrow H^\alpha_v(q, \psi)$ such that:

$$f(X_a) := \sum_{k \in K^\alpha} y_a(k)e(k),$$

$$f(T_a) := \sum_{k \in K^\alpha} (\psi_a Q_a(k) - P_a(k)) e(k),$$

and, recalling (3.11):

$$g(e(k)) := e(k),$$

$$g(y_a) := \sum_{k \in K^\alpha} (1 - y_{-k} \cdot q^{-k} X_a) e(k),$$

$$g(\psi_a) := \sum_{k \in K^\alpha} (T_a + P_a(k)) Q_a(k)^{-1} e(k).$$

Moreover, these homomorphisms are inverse to each other, hence $H^\alpha_v(q, \psi) \simeq R^\alpha_v(\Gamma)$.

We will explain at the beginning of §3.3.2 how the elements $P_a(k)$ and $Q_a(k)$ are considered as elements of $H^\alpha_v(q, \psi)$. We note that there exist such families $\{Q_a(k)\}_{a,k}$, see §4.1 for further details.
3.3 Proof of Theorems 3.4 and 3.17

In this subsection, we first check that the maps of Theorem 3.17 indeed define algebras homomorphisms: we check that the different defining relations (1.2b)–(1.2f), (1.6) (for \( f \)) and (2.1), (2.5) (for \( g \)) are satisfied. The proof is exactly as in [BrKl, Section 4]: we will only give some details when some \( v_j \) are involved. The remaining parts of the argument require only notational changes from [BrKl].

3.3.1 The map \( f \) is a homomorphism

We prove that the images of the generators of \( \mathcal{H}_n^\Lambda(q,v) \) by \( f \) satisfy the defining relations.

The proof of the quadratic relation (1.2b) is exactly the same as the one for [BrKl, Theorem 4.3]. Namely, it suffices to check that for any \( k \in K^\alpha \) we have \( f(T_a)^2 e(k) = (q-1) f(T_a) e(k) + q e(k) \), and the result follows since \( \sum_{k \in K^\alpha} e(k) = 1 \) in \( R_n^\Lambda(\Gamma) \).

The equality \( f(X_1) f(X_2) = f(X_2) f(X_1) \) is clear. Hence, to check the length 4-braid relation (1.2c) it suffices to prove that \( q f(X_2) = f(T_1) f(X_1) f(T_1) \). We will in fact prove that for any \( a \in \{1, \ldots, n-1\} \):

\[
q f(X_{a+1}) = f(T_a) f(X_a) f(T_a).
\]  
(3.18)

Since we have just checked the relation (1.2b) for \( f(T_a) \), it suffices to prove that for any \( k \in K^\alpha \):

\[
f(X_a) f(T_a) e(k) = (f(T_a) + 1 - q) f(X_{a+1}) e(k).
\]

Once again, the rest of the proof is exactly the same as in the corresponding part of the proof of [BrKl, Theorem 4.3]. We write down here some of the details since we have to add some \( v_j \) in the calculations. We have:

\[
X_a T_a e(k) = (y_a(s_a \cdot k) v_a Q_a(k) - y_a(k) P_a(k)) e(k)
\]

\[
= (\psi_a y_a(k) Q_a(k) + \delta_{k_a k_a+1} v_k q^k Q_a(k) - y_a(k) P_a(k)) e(k),
\]

and:

\[
(T_a + 1 - q) X_{a+1} e(k) = (\psi_a Q_a(k) - P_a(k) + 1 - q) y_{a+1} e(k).
\]

Considering the two cases \( k_a \neq k_{a+1} \) and \( k_a = k_{a+1} \) separately and using (3.9), (3.10) and (3.14), we can easily prove that the two above quantities are equal.

The commutation relations (1.2d) and (1.2e) are straightforward from the defining relations in \( R_n^\Lambda(\Gamma) \), and for (1.2f) we can reproduce the corresponding part of the proof of [BrKl, Theorem 4.3].

Finally, let us prove that the cyclotomic relation (1.6) is satisfied, that is:

\[
\prod_{k \in K} (f(X_1) - v_k q^k)^{\Lambda_k} = 0.
\]

We have, using (2.1a) and (2.1b):

\[
\prod_{k \in K} (f(X_1) - v_k q^k)^{\Lambda_k} = \prod_{k \in K} \left[ \sum_{k \in K^\alpha} (v_k q^k (1 - y_1) - v_k q^k)^{\Lambda_k} e(k) \right]
\]

\[
= \prod_{k \in K} \left[ \sum_{k \in K^\alpha} (v_k q^k (1 - y_1) - v_k q^k)^{\Lambda_k} e(k) \right]
\]

\[
= \sum_{k \in K^\alpha} \prod_{k \in K} (v_k q^k (1 - y_1) - v_k q^k)^{\Lambda_k} e(k).
\]

By (2.5), for \( k \in K^\alpha \) the term for \( k = k_1 \) vanishes, hence we get the result.

To conclude, the map \( f : \mathcal{H}_n^\Lambda(q,v) \to R_n^\Lambda(\Gamma) \) defined on the generators \( X_1, T_1, \ldots, T_{n-1} \) yields a homomorphism of algebra. By restriction, we get an algebra homomorphism \( f : \mathcal{H}_n^\Lambda(q,v) \to R_n^\Lambda(\Gamma) \). In particular, the image of \( X_a \) for \( a > 1 \) is the one given in Theorem 3.17, thanks to (1.3) and (3.18).
3.3.2 The map \( g \) is a homomorphism

In this paragraph, for any \( m \in R^A_\alpha(\Gamma) \) we also write \( m := g(m) \in H^A_\alpha(q, v) \). In particular, we have:

\[
y_a = \sum_{k \in K^\alpha} (1 - v_{-k_a} q^{-k_a} X_a) e(k) \in H^A_\alpha(q, v),
\]

thus we can consider the power series \( P_a(k) \) and \( Q_a(k) \) as elements of \( H^A_\alpha(q, v) \), namely:

\[
\psi_a = \sum_{k \in K^\alpha} (T_a + P_a(k)) Q_a(k)^{-1} e(k) \in H^A_\alpha(q, v).
\]

Following Lusztig, define the following “intertwining element” in \( H^A_\alpha(q, v) \) for \( a \in \{1, \ldots, n-1\} \) by:

\[
\Phi_a := T_a + (1 - q) \sum_{k \in K^\alpha, k_a \neq k_{a+1}} (1 - X_a X_{a+1}^{-1})^{-1} e(k) + \sum_{k \in K^\alpha, k_a = k_{a+1}} e(k),
\]

where \((1 - X_a X_{a+1}^{-1})^{-1} e(k)\) denotes the inverse of \((1 - X_a X_{a+1}^{-1}) e(k)\) in \( e(k) H^A_\alpha(q, v) e(k) \). Noticing that \( y_a(k) e(k) = X_a e(k) \), we can check the following equality:

\[
\Phi_a = \sum_{k \in K^\alpha} (T_a + P_a(k)) e(k).
\]

We can give an analogue of [BrKl, Lemma 4.1]. Once again, we just have to write \( a \) (respectively \( k, k \)) instead of their \( r \) (resp. \( i, i \)), both in the statements and the proofs. Among all the relations in the lemma, we will make here an explicit use of the following one:

\[
X_{a+1} \Phi_a e(k) = \begin{cases} 
\Phi_a X_a e(k) & \text{if } k_a \neq k_{a+1}, \\
\Phi_a X_a e(k) + (q X_{a+1} - X_a) e(k) & \text{if } k_a = k_{a+1}.
\end{cases}
\]

(3.19)

We now check the different relations of \( R^A_\alpha(\Gamma) \). Relations (2.1a)–(2.1g), (2.1i)–(2.1k) and (2.5) follows as in the corresponding part of the proof of [BrKl, Theorem 4.2]. To check (2.1l), again we just follow the corresponding part of the proof of [BrKl, Theorem 4.2], but we need to add some \( v_j \)'s. We have:

\[
y_{a+1} \psi_a e(k) = (1 - v_{-k_a} q^{-k_a} X_{a+1}) \Phi_a Q_a(k)^{-1} e(k).
\]

If \( k_a \neq k_{a+1} \), using (3.19) we get:

\[
y_{a+1} \psi_a e(k) = \Phi_a Q_a(k)^{-1} (1 - v_{-k_a} q^{-k_a} X_a) e(k) = \psi_a y_a e(k),
\]

whereas if \( k_a = k_{a+1} \) we obtain:

\[
y_{a+1} \psi_a e(k) = (1 - v_{-k_a} q^{-k_a} X_{a+1})(T_a + 1) Q_a(k)^{-1} e(k)
\]

\[
= ((T_a + 1)(1 - v_{-k_a} q^{-k_a} X_a) + v_{-k_a} q^{-k_a} X_a - v_{-k_a} q^{-k_a} X_a - v_{-k_a} q^{-k_a} X_{a+1}) Q_a(k)^{-1} e(k)
\]

\[
= (\psi_a y_a + 1) e(k),
\]

since \((v_{-k_a} q^{-k_a} X_a - v_{-k_a} q^{-k_a} X_{a+1}) e(k) = Q_a(k) e(k)\). The proof of (2.1h) is similar.

3.3.3 Conclusion

As in [BrKl, Lemma 3.4], we have:

\[
f(e(k)) = e(k) \in R^A_\alpha(\Gamma),
\]

for all \( k \in K^\alpha \). It is now an easy exercise to show that \( f \circ g \) is the identity of \( R^A_\alpha(\Gamma) \), and then that \( g \circ f \) is the identity of \( H^A_\alpha(q, v) \). Hence, the homomorphisms \( f \) and \( g \) are inverse isomorphisms and Theorem 3.17 is proved. Summing the \( F \)-isomorphism \( H^A_\alpha(q, v) \simeq R^A_\alpha(\Gamma) \)}
over all \( \alpha \models K_n \), we thus get the statement of Theorem 3.4. Note that since \( \mathcal{H}^\Lambda_{p,n}(q,v) \) is zero for all but finitely many \( \alpha \), the same thing happens for \( \mathcal{R}^\Lambda_{p,n}(\Gamma) \). In particular, the direct sum:

\[
\mathcal{R}^\Lambda_{n}(\Gamma) = \bigoplus_{\alpha \models K_n} \mathcal{R}^\Lambda_{\alpha}(\Gamma),
\]

has a finite number of non-vanishing terms.

### 3.4 An unexpected corollary

For \( j \in J' \), let us write \( \Lambda^j \) for the restriction of \( \Lambda \) to \( I \times \{j\} \cong I \). Since \( \Gamma \) is given by \( p' \) disjoint copies of the quiver \( \Gamma_e \), we know from [Ro, Theorem 6.30] that there is an algebra isomorphism:

\[
\mathcal{R}^\Lambda_{p,n}(\Gamma) \cong \bigoplus_{\lambda \models j,n} \text{Mat}_{m_\lambda} \left( \mathcal{R}^\Lambda_{\lambda_j}(\Gamma_e) \otimes \cdots \otimes \mathcal{R}^\Lambda_{\lambda_{p'}}(\Gamma_e) \right),
\]

where \( m_\lambda = \frac{n!}{n_1! \cdots n_{p'}} \). For any \( j \in J' \), we set:

\[
\mathcal{H}^\Lambda_{\lambda_j}(q) := \mathcal{H}^\Lambda_{\lambda_j}(q, \nu_{\text{triv}}),
\]

where \( \nu_{\text{triv}} \) has only one coordinate, equal to 1. In particular, we saw from Theorem 3.4 or [BrKl] that we have the \( F \)-isomorphism \( \mathcal{H}^\Lambda_{\lambda_j}(q) \cong \mathcal{R}^\Lambda_{\lambda_j}(\Gamma_e) \). We deduce the following result.

**Theorem 3.20.** Let \( v \in (F^\times)^{p'} \) as in §3.1. We have an (explicit) \( F \)-algebra isomorphism:

\[
\mathcal{H}^\Lambda_{n}(q,v) \cong \bigoplus_{\lambda \models j,n} \text{Mat}_{m_\lambda} \left( \mathcal{H}^\Lambda_{\lambda_j}(q) \otimes \cdots \otimes \mathcal{H}^\Lambda_{\lambda_{p'}}(q) \right).
\]

In particular, the algebras \( \mathcal{H}^\Lambda_{p,n}(q,v) \) and \( \bigoplus_{\lambda \models j,n} \mathcal{H}^\Lambda_{\lambda_j}(q) \otimes \cdots \otimes \mathcal{H}^\Lambda_{\lambda_{p'}}(q) \) are Morita equivalent. Note that since the following condition is satisfied (recall (3.1)):

\[
\prod_{1 \leq j < j' \leq p'} \prod_{i,j \in I} \prod_{-n < a < n} \left( q^{a} (v_j q^{j}) - v_{j'} q^{j'} \right) \in F^\times,
\]

the Morita equivalence is known by [DiMa, Theorem 1.1]. Therefore, Theorem 3.20 provides an explicit isomorphism for which the Morita equivalence of [DiMa] follows.

**Remark 3.21.** If \( \Lambda^1 = \cdots = \Lambda^{p'} \), by [PA, Corollary 3.2] or [Ro] we know that the algebra of Theorem 3.20 is a cyclotomic Yokonuma–Hecke algebra of type \( A \), as introduced in [ChPA].

### 4 A presentation for \( \mathcal{H}^\Lambda_{p,n}(q) \)

In this section, we prove our second main result, given in Corollary 4.16: we give a cyclotomic quiver Hecke-like presentation for \( \mathcal{H}^\Lambda_{p,n}(q) \). The key is to make a careful choice for the family \( \{Q_a(k)\}_{a,k} \).

#### 4.1 A nice family

We consider the quiver \( \Gamma \) with vertex set \( V = \{v_j q^i\}_{i,j \in J'} \cong K = I \times J' \) of §3.1, where \( v_1, \ldots, v_{p'} \in F^\times \) satisfy (3.1). We give here a particular choice for the family \( \{Q_a(k)\}_{a,k} \). We recall the definition of the family \( \{P_a(k)\}_{a,k} \) of (3.9).

**Lemma 4.1 ([StWe, (5.4)])**. The family \( \{Q_a(k)\}_{1 \leq a < n, k \in K_n} \) given by:

\[
Q_a(k) := \begin{cases} 
- q + q y_{a+1} - y_a & \text{if } k_a = k_{a+1}, \\
1 - \frac{1 - P_a(k)}{y_{a+1} - y_a} & \text{if } k_a \preceq k_{a+1}, \text{ or } k_a \triangleright k_{a+1}, \\
1 - P_a(k) & \text{otherwise,}
\end{cases}
\]

satisfies the property (BK).
3.15. Let us now check that (BK) is satisfied. First, the element \(y\) will see in Remark 4.2 follows from the above calculations so (BK) holds. The proof of Lemma 4.15 would be the following one:

\[
Q_{\alpha}^{BK}(k) := \begin{cases} 
1 - q + y a - y a & \text{if } k a = k a + 1, \\
(y a(k) - y a(k + 1))/y a(k) - y a(k) & \text{if } k a \not= k a + 1, \\
(y a(k) - y a(k + 1))/y a(k) - y a(k))^2 & \text{if } k a \not= k a + 1, \\
v k a q^{k a} & \text{if } k a \not= k a + 1. 
\end{cases}
\] (4.3)

We will see in Remark 4.15 why the choice of Lemma 4.1 is more adapted to our problem. For the convenience of the reader, we will now give a proof of Lemma 4.1.

Proof of Lemma 4.1. First, let us prove that \(Q_{\alpha}(k)\) is well-defined. If \(k a \neq k a + 1\) we have

\[
P_{\alpha}(k) = \frac{1 - q y a(k)}{y a(k) - y a(k)}
\]

In particular, if \(k a \not= k a + 1\) or \(k a \not= k a + 1\) we get (recall Remark 4.2):

\[
1 - P_{\alpha}(k) = \frac{v k a q^{k a}(y a(k) - y a(k))}{y a(k) - y a(k)}
\]

which is well-defined.

As suggested in [StWe], we now notice that, if \(k a \neq k a + 1\):

\[
(1 - P_{\alpha}(s a \cdot k))^{s a} = q + P_{\alpha}(k).
\] (4.4)

This is a straightforward consequence of the equality \(P_{\alpha}(k) + P_{\alpha}(s a \cdot k)^{s a} = 1 - q\) (see [BrKl, (4.28)]). Let us now check that (BK) is satisfied. First, the element \(Q_{\alpha}(k)\) is of course invertible when \(k a = k a + 1\) (since \(1 - q \neq 0\)), and the invertibility in the remaining cases follows from the above calculations so (3.13) holds. Moreover, equation (3.14) is true by definition.

We now check the different relations (3.15) involving \(Q_{\alpha}(k)Q_{\alpha}(s a \cdot k)^{s a}\). If \(k a \not= k a + 1\) (in particular, \(k a \not= k a + 1\) then \(Q_{\alpha}(k) = 1 - P_{\alpha}(k)\) and we immediately deduce (3.15a) from (4.4). If \(k a \not= k a + 1\) then \(Q_{\alpha}(k) = 1 - P_{\alpha}(k)\) and \(Q_{\alpha}(s a \cdot k) = \frac{1 - P_{\alpha}(s a \cdot k)}{y a(k) - y a(k)}\). Thus:

\[
Q_{\alpha}(k)Q_{\alpha}(s a \cdot k)^{s a} = (1 - P_{\alpha}(k)) \frac{q + P_{\alpha}(k)}{y a(k) - y a(k)}
\]

so (3.15b) holds. The proof of (3.15c) is similar. If now \(k a \not= k a + 1\) then \(Q_{\alpha}(k) = \frac{1 - P_{\alpha}(k)}{y a(k) - y a(k)}\) and \(Q_{\alpha}(s a \cdot k) = \frac{1 - P_{\alpha}(s a \cdot k)}{y a(k) - y a(k)}\), thus:

\[
Q_{\alpha}(k)Q_{\alpha}(s a \cdot k)^{s a} = \frac{1 - P_{\alpha}(k)}{y a(k) - y a(k)} \frac{q + P_{\alpha}(k)}{y a(k) - y a(k)}
\]

so (3.15d) holds.

Finally, to prove equation (3.16) it suffices to see that \(P_{\alpha+1}(s a_{n+1} \cdot s a \cdot k)^{s a} = P_{\alpha}(s a s a_{n+1} \cdot k)^{s a+1}\). This equality follows from [BrKl, (4.29)] and the braid relation \(s a_{n+1} s a = s a_{n+1} s a s a_{n+1}\).

Remark 4.5. We deduce from the calculations made at the beginning of the proof of Lemma 4.1 that \(Q_{\alpha}(k) = Q_{\alpha}^{BK}(k)\) if \(k a = k a + 1, k a \not= k a + 1\) or \(k a \not= k a + 1\).
4.2 Intertwining

In this subsection, we show how our previous works allow us to prove our main result (Corollary 4.16). For \( j \in J' \), let us set \( v_j : = \zeta^j \); it follows from the definition of \( p' \) that \( v_1, \ldots, v_{p'} \) satisfy the distinct orbit condition (3.1). In particular, the vertex set of \( \Gamma \) is \( V = \{ \zeta^iq^i \}_{i \in I, j \in J'} \). Let us consider a weight \( \Lambda = (\Lambda_k)_{k \in K} \) of level \( r \), such that:

\[
\Lambda_{i,j} = \Lambda_{i,j'} = : \Lambda_i, \quad \text{for all } i \in I \text{ and } j, j' \in J'.
\]  

We suppose that the associated tuple \( \Lambda = (\Lambda_i)_{i \in I} \), of level \( \omega d \), satisfies the condition of Proposition 1.33, that is (recall the notation \( \eta \) of (1.23)):

\[
\Lambda_1 = \Lambda_{i+\eta}, \quad \text{for all } i \in I,
\]  

so that the algebras \( H_n^\Lambda(q, \zeta), H_{p,n}^\Lambda(q) \) (recall Definition 1.35) and the shift automorphism of \( H_n^\Lambda(q, \zeta) \) (recall Proposition 1.9) are well-defined. We will use the above condition (4.7) and the results of §2.3 to define a particular automorphism \( \sigma \) of \( \mathcal{R}_n^\Lambda(\Gamma) \).

Let us define \( \sigma : V \to V \) by:

\[
\sigma(v) := \zeta v,
\]

for all \( v \in V \). Note that \( \sigma \) is well-defined since \( V \) is also given by \( \{ \zeta^iq^i \}_{i \in I, j \in J} \). Moreover, the reader may have noticed the similarity with the map of Proposition 1.9.

**Lemma 4.9.** The map \( \sigma : V \to V \) defined on the vertices of \( \Gamma \) satisfies the assumptions of §2.3, that is:

- the map \( \sigma : V \to V \) is a bijection;
- if \( (v, v') \) is an edge of \( \Gamma \) then \( (\sigma(v), \sigma(v')) \) is also an edge of \( \Gamma \);
- for any \( p_1 \in \{1, \ldots, p - 1\} \) and any vertex \( v \in V \) we have \( \sigma^{p_1}(v) \neq v = \sigma^p(v) \).

**Proof.** Since \( \zeta \) is a primitive \( p \)th root of unity, we deduce that the first and third points are satisfied. It remains to prove the second one. Let \( (v, v') \) be an edge of \( \Gamma \). By definition, we have \( v' = qv \), thus \( \zeta v' = \zeta(qv) = q(\zeta v) \). Hence, we have \( \sigma(v') = q\sigma(v) \): we have proved that \( (\sigma(v), \sigma(v')) \) is an edge of \( \Gamma \).

The action of \( \sigma \) on \( V \) is algebraically easy. Let us now describe how \( \sigma \) acts “graphically” on the set \( V \) of the vertices of \( \Gamma \), that is, on \( K = I \times J' \). Let \( i \in I, j \in J' \) and set \( v := \zeta^iq^i \). We have:

\[
\sigma(\zeta^iq^i) = \zeta^{i+1}q^i.
\]  

Hence, if \( j < p' \) then \( \sigma \) just translates the vertex \( v \) to the copy of \( \Gamma_v \) directly on its right. If \( j = p' \), we have \( j + 1 = p' + 1 \notin J' \) thus we write:

\[
\sigma(\zeta^{p'}q^i) = \zeta^{p'}q^i = \zeta^{i+\eta}q^i.
\]

It means that \( v \) is translated to the first copy of \( \Gamma_v \) and rotated by \( \eta \). Note that depending on \( \Gamma_v \), there may not be any translation or rotation. With the examples of Figure 2, that gives:

- **case** \((e, p) = (2, 3)\) we have \( p' = 3, \eta = 0 \) and the map \( \sigma \) is given by the product of 3-cycles \((0_1, 0_2, 0_3)(1_1, 1_2, 1_3);\)
- **case** \((e, p) = (2, 6)\) we have \( p' = 3, \eta = 1 \) and the map \( \sigma \) is given by the 6-cycle \((0_1, 0_2, 0_3, 1_1, 1_2, 1_3);\)
- **case** \((e, p) = (\infty, 2)\) we have \( p' = 2, \eta = 0 \) and the map \( \sigma \) is given by the product of transpositions \( \prod_{i \in I} (i_1, i_2). \)

In particular, note that \( \sigma \) has indeed order \( p \).

By Theorem 2.14 and Lemma 2.31, the permutation \( \sigma \) of the vertices of \( V \) induces an isomorphism \( \mathcal{R}_n^\Lambda(\Gamma) \to \mathcal{R}_n^{\alpha\Lambda}(\Gamma) \) for any \( \alpha \models_K n \). Let us now check that the weight \( \Lambda \) satisfies the \( \sigma \)-stability condition (2.32).
Proposition 4.12. For any \( k \in K = I \times J' \) we have \( \Lambda_k = \Lambda_{\sigma(k)} \).

Proof. We have seen above that for \((i, j) \in I \times J'\):

- if \( j < p' \) then \( \sigma(i, j) = (i, j + 1) \);
- if \( j = p' \) then \( \sigma(i, j) = (i + \eta, 1) \).

Thus, we deduce the result from (4.6) and (4.7).

By Lemma 2.33, we know that the map \( \sigma \) induces an automorphism of the cyclotomic quiver Hecke algebra \( R_n^A(\Gamma) \). We will refer to it as the \textit{shift automorphism} of \( R_n^A(\Gamma) \).

Lemma 4.13. The power series \( y_a(k) \), \( P_a(k) \) and \( Q_a(k) \) of \( R_n^A(\Gamma) \) are shift-invariant. Moreover:

\[
\begin{align*}
y_a(\sigma(k)) &= \zeta y_a(k), \\
P_a(\sigma(k)) &= P_a(k), \\
Q_a(\sigma(k)) &= Q_a(k).
\end{align*}
\]

Proof. The first statement is clear since \( y_a \) and \( y_{a+1} \) are shift-invariant (by definition, just recall Theorem 2.14). Recall that \( V = \{q'^i q^j\}_{i,j} \in J' \isom K \) is the vertex set of \( \Gamma \). The image of \( k \in K^n \) in \( V^n \) is \( (\zeta^{k_1} q^{i_1}, \ldots, \zeta^{k_n} q^{i_n}) \), where \( \zeta^{k_1} q^{i_1} = \zeta q^{i_1} \) if \( k = (i, j) \) (recall (3.11)). In particular, the image of \( \sigma(k) \) in \( V^n \) is \( (\zeta^{k_1} q^{i_1}, \ldots, \zeta^{k_n} q^{i_n}) \). Thus, we have:

\[
y_a(\sigma(k)) = \zeta y_a(k) - y_a(k) = \zeta y_a(k).
\]

Hence, if \( k_a = k_{a+1} \) then by Lemma 2.12 we have \( P_a(k) = P_a(\sigma(k)) \), and if \( k_a \neq k_{a+1} \) we have:

\[
P_a(\sigma(k)) = (1 - q)(1 - y_a(\sigma(k)))y_{a+1}(\sigma(k))^{-1})^{-1} = (1 - q)((1 - \zeta y_a(k)y_{a+1}(k))^{-1})^{-1} = P_a(k).
\]

The last equality \( Q_a(\sigma(k)) = Q_a(k) \) is now obvious.

Let us now denote by \( \tilde{\sigma} : \mathcal{H}_n^A(q, \zeta) \to \mathcal{H}_n^A(q, \zeta) \) the shift automorphism of \( \mathcal{H}_n^A(q, \zeta) \) (defined in Proposition 1.9). Recalling the choice for \( v \) that we made at the beginning of §4.2, we consider the \( F \)-algebra isomorphism \( f : \mathcal{H}_n^A(q, \zeta) \to R_n^A(\Gamma) \) from Theorems 3.4 and 3.17, defined with the family \( \{Q_a(k)\}_{a,k} \) of Lemma 4.1.

Theorem 4.14 (Main theorem). We have \( \sigma^{-1} \circ f = f \circ \tilde{\sigma} \).

Proof. Since we deal with algebra homomorphisms, it suffices to check the equality on the generators \( S, T_1, \ldots, T_{n-1} \) of \( \mathcal{H}_n^A(q, \zeta) \). We successively have, using Lemma 4.13 (recall that, by definition, \( S = X_1 \)):

\[
\begin{align*}
\sigma^{-1} \circ f(S) &= \sum_{k \in K^n} \sigma^{-1}(y_1(k)e(k)) \\
&= \sum_{k \in K^n} y_1(k)e(\sigma^{-1}(k)) \\
&= \sum_{k \in K^n} y_1(\sigma(k))e(k) \\
&= \zeta f(S) \\
&= f(\zeta S) \\
&= f \circ \tilde{\sigma}(S).
\end{align*}
\]
and:
\[
\sigma^{-1} \circ f(T_a) = \sum_{k \in K^n} \sigma^{-1}(\psi_a Q_a(k) - P_a(k))e(k)
\]
\[
= \sum_{k \in K^n} [\psi_a Q_a(k) - P_a(k)]e(\sigma^{-1}(k))
\]
\[
= \sum_{k \in K^n} [\psi_a Q_a(\sigma(k)) - P_a(\sigma(k))]e(k)
\]
\[
= \sum_{k \in K^n} [\psi_a Q_a(k) - P_a(k)]e(k)
\]
\[
= f(T_a)
\]
\[
= f \circ \sigma(T_a).
\]

Note that the above sums over $K^n$ are in fact finite, since all but finitely many $e(k) \in R^A_n(\sigma)$ are zero (recall, for instance, §3.3.3).

**Remark 4.15.** Theorem 4.14 fails if we consider the homomorphism $f$ built from the family $\{Q^A_{a,k}(k)\}_{a,k}$. For instance, Lemma 4.13 is no longer valid with $Q^A_{a,k}(k)$, since if $k_a \leftarrow k_{a+1}$:

\[
Q^A_{a,k}(\sigma(k)) = \zeta k_a q^A = \zeta Q^A_{a,k}(k),
\]

and the same result holds if $k_a \rightarrow k_{a+1}$.

We now recall some notation and facts from §2.3. If $\alpha \models K n$, we denote by $[\alpha]$ its orbit under the action of $\langle \sigma \rangle$ (this action is defined in Lemma 2.13). We have an associated subset $K^{[\alpha]} = \cup_{[\beta] \models [\alpha]} K^\beta$ of $K^n$ (see (2.16)). The quotient set of $K^{[\alpha]}$ by the equivalence relation $\sim$ generated by $k \sim \sigma(k)$ for all $k \in K^{[\alpha]}$ is $K^{[\alpha]}$ (Definition 2.21). Each equivalence class $\gamma \in K^{[\alpha]}$ has cardinality $p$, and is given by $\gamma = \{k, \sigma(k), \ldots, \sigma^{p-1}(k)\}$ for some $k \in K^{[\alpha]}$ (see (2.22)). Finally, thanks to the canonical map $K^n/\sim \rightarrow (K/\sim)^n$ and Lemma 4.9, for any $\gamma \in K^{[\alpha]}$ and $a \in \{1, \ldots, n\}$ we have well-defined statements $\gamma_a = \gamma_{a+1}, \gamma_a \rightarrow \gamma_{a+1}$, etc. (see Lemma 2.12 and before Remark 2.26). Moreover, since $\Lambda$ is $\sigma$-stable (Proposition 4.12) the integer $\Lambda_{\gamma_a}$ is well-defined.

**Corollary 4.16.** The $F$-algebra isomorphism $f : H^A_{p,n} (q, \zeta) \rightarrow R^A_n(\Gamma)^\sigma$. Hence, we have the following $F$-algebra isomorphism:

\[
H^A_{p,n} (q, \zeta) \simeq \bigoplus_{[\alpha]} R^A_{[\alpha]}(\Gamma)^\sigma,
\]

where $[\alpha]$ runs over the orbits of the $K$-compositions of $n$ under the action of $\langle \sigma \rangle$, and the subalgebra $H^A_{p,[\alpha]}(q)$ has a presentation given by the generators

\[
\{e(\gamma)\}_{\gamma \in K^{[\alpha]}} \cup \{y_1, \ldots, y_n\} \cup \{\psi_1, \ldots, \psi_{n-1}\},
\]

and the relations (2.29) and (2.36).

**Proof.** Using Theorem 4.14, for $h \in H^A_{n} (q, \zeta)$ we have:

\[
\bar{\sigma}(h) = h \iff f \circ \bar{\sigma}(h) = f(h) \iff \sigma^{-1} \circ f(h) = f(h) \iff f(h) = \sigma \circ f(h),
\]

hence:

\[
h \text{ is fixed under } \bar{\sigma} \iff f(h) \text{ is fixed under } \sigma.
\]

Using Corollary 1.18, we get:

\[
H^A_{p,n} (q) \simeq H^A_{n} (q, \zeta)^\sigma \simeq R^A_n(\Gamma)^\sigma,
\]

as desired. We deduce the second statement from the equality $R^A_n(\Gamma)^\sigma = \bigoplus_{[\alpha]} R^A_{[\alpha]}(\Gamma)^\sigma$ (note that this direct sum is finite by Theorem 3.17) and Theorem 2.43, where we gave a presentation for $R^A_{[\alpha]}(\Gamma)^\sigma$. 

\[29\]
Recall from Remark 2.47 that \( R_n^\Lambda(\Gamma) \) is naturally \( \mathbb{Z} \)-graded. From this grading, Theorem 3.4 and the isomorphism \( f \), we can endow \( H_n^\Lambda(q, \zeta) \) with a (non-trivial) \( \mathbb{Z} \)-grading.

**Corollary 4.17.** The shift automorphism \( \tilde{\sigma} : H_n^\Lambda(q, \zeta) \to H_n^\Lambda(q, \zeta) \) is homogeneous with respect to the previous grading. Moreover, the subalgebra \( H_{p,n}^\Lambda(q) \) is a graded subalgebra of \( H_n^\Lambda(q, \zeta) \).

**Proof.** Recall from Remark 2.47 that \( \sigma : R_n^\Lambda(\Gamma) \to R_n^\Lambda(\Gamma) \) is homogeneous and that \( R_n^\Lambda(\Gamma)^{\sigma} \) is a graded subalgebra. We thus deduce the first assertion from Theorem 4.14 and the second one from Corollary 4.16.

We now give an analogue of a classical corollary of [BrKl, Theorem 1.1].

**Corollary 4.18.** If \( \tilde{q} \in F \setminus \{0, 1\} \) has the same order \( e \in \mathbb{N}_{\geq 2} \cup \{\infty\} \) as \( q \) then:

\[
H_{p,n}^\Lambda(q) \simeq H_{p,n}^\Lambda(\tilde{q}),
\]

as \( F \)-algebras.

**Proof.** We know from Lemma 1.21 and Theorem 3.4 that the algebras \( H_n^\Lambda(q) \) and \( H_n^\Lambda(\tilde{q}) \) are isomorphic to the same quiver Hecke algebra \( R_n^\Lambda(\Gamma) \). Moreover, we have the following isomorphism:

\[
H_{p,n}^\Lambda(q) \simeq R_n^\Lambda(\Gamma)^{\sigma},
\]

where \( \sigma \) is uniquely determined by the quiver \( \Gamma \) and the element \( \eta \in I \) such that \( q^\eta = \zeta^\nu \). To prove that \( H_{p,n}^\Lambda(q) \simeq H_{p,n}^\Lambda(\tilde{q}) \), it thus suffices to prove that there is a primitive \( p \)th root of unity \( \tilde{\zeta} \in F^\times \) such that:

\[
\tilde{q}^\eta = \tilde{\zeta}^\nu.
\]

To deal with the case \( e = \infty \), it suffices to set \( \tilde{\zeta} := \zeta \) (recall that, in that case, we have \( \eta = 0 \) and \( \nu = p \)). Hence, we now assume that \( e < \infty \). Since \( q \) and \( \tilde{q} \) are both primitive \( e \)th roots of unity, there is some \( a \in \mathbb{Z} \), invertible modulo \( e \), such that \( \tilde{q} = q^a \). In particular, for any \( k \in \mathbb{Z} \) we have \( \tilde{q} = q^{a + ke} \). Since \( q^\eta = \zeta^\nu \), we get:

\[
\tilde{q}^\eta = (\zeta^{a + ke})^\nu.
\]

Therefore, it suffices to prove that there is some \( k \in \mathbb{Z} \) such that \( a + ke \) is invertible modulo \( p \), that is, such that \( \tilde{\zeta} := \zeta^{a + ke} \) is a primitive \( p \)th root of unity. A quick (but very powerful) argument is to use Dirichlet’s theorem about arithmetic progression (see also [Hu07, Lemma 3.5]): since \( a \) and \( e \) are coprime, the set \( \{a + ke\}_{k \in \mathbb{N}} \) contains infinitely many prime numbers. In particular, it contains a prime \( \varphi \) which does not divide \( p \), hence which is coprime to \( p \). It now suffices to choose \( k \in \mathbb{N} \) such that \( \varphi = a + ke \).

## A About \( H_{p,n}^\Lambda(q) \)

The aim of this appendix is to give details for the statements of Remarks 1.15 and 1.16.

### A.1 Case \( p = 1 \)

We prove here the statement of Remark 1.15: the presentation of \( H_{p,n}^\Lambda(q) \) given at §1.2 gives the Ariki–Koike algebra \( H_n^\Lambda(q) = H_n^\Lambda(q, 1) \) of §1.1. Note that since \( p = 1 \), the relation (1.14i) becomes \( st_1^i = t_1 s \), thus we have:

\[
t_1^i = s^{-1} t_1 s.
\]

The result follows from the theorem below.
**Theorem A.2.** The algebra homomorphisms \( \phi : \mathcal{H}_{1,n}^\Lambda(q) \to \mathcal{H}_{n}^\Lambda(q) \) and \( \psi : \mathcal{H}_{n}^\Lambda(q) \to \mathcal{H}_{1,n}^\Lambda(q) \) given by:

\[
\begin{align*}
\phi(s) & := S, \\
\phi(t'_1) & := S^{-1}T_1S, \\
\phi(t_a) & := T_a, \quad \text{for all } a \in \{1, \ldots, n-1\},
\end{align*}
\]

and:

\[
\begin{align*}
\psi(S) & := s, \\
\psi(T_a) & := t_a, \quad \text{for all } a \in \{1, \ldots, n-1\},
\end{align*}
\]

are well-defined and inverse to each other.

**Proof.** We first check that \( \psi \) is an algebra homomorphism: all relations are straightforward except \( (1.1.4c) \), but it follows from \( (1.14b) \) and (A.1). Concerning \( \phi \), again all relations are straightforward, except \( (1.14d) \) (if \( n \geq 3 \)). Note the following consequence of \( (1.2c) \):

\[
S^{-1}T_1ST_1 = T_1ST_1S^{-1}.
\]  

(A.3)

In the following calculation, we adopt the following conventions:

- we use color when a quantity simplifies;
- we use underbrace when we will use a relation;
- we use parenthesis when we did use a relation.

We have:

\[
\begin{align*}
\phi(t'_1)\phi(t_1)\phi(t_2)\phi(t'_1)\phi(t_1)\phi(t_2) & = \phi(t_2)\phi(t'_1)\phi(t_1)\phi(t_2)\phi(t'_1)\phi(t_1) \\
\iff [S^{-1}T_1S][T_1T_2][S^{-1}T_1S][T_1T_2] & = T_2[S^{-1}T_1S][T_1T_2][S^{-1}T_1S][T_1T_2] \\
\iff S^{-1}T_1ST_1T_2T_1S^{-1} & = (S^{-1}T_2)T_1ST_2T_1(T_1ST_1S^{-1}) \\
\iff T_1S(T_2T_1T_2S)T_1S^{-1} & = T_2T_1S(T_2T_1T_2S)T_1S^{-1} \\
\iff T_1(T_2S)T_1S(T_2T_1T_2S)T_1 & = T_2T_1S(T_2T_1T_2S)T_1 \\
\iff T_1ST_1S(T_1T_2T_1) & = (T_1T_2T_1)ST_1T_2T_1 \\
\iff ST_1S & = T_1ST_1S,
\end{align*}
\]

which allows us to conclude. Finally, the composition \( \phi \circ \psi \) is the identity on the set of generators \( \{S, T_1, \ldots, T_{n-1}\} \), and using (A.1) we find that \( \psi \circ \phi \) is the identity on the set of generators \( \{s, t'_1, t_1, \ldots, t_{n-1}\} \). Hence, the algebras homomorphisms \( \phi \) and \( \psi \) are inverse isomorphisms and this concludes the proof.

**A.2 Two equivalent relations**

We suppose that \( p \geq 2 \). We prove here the statement of Remark 1.16: in the algebra \( \mathcal{H}_{p,s}^\Lambda(q) \), the relations \( (1.14f) \) and \( (1.14g) \) are equivalent. We will even prove a slightly more general statement (cf. Proposition A.6). Let \( A \) be a unitary ring and \( q \in A^\times \) an invertible element. Let \( s, t'_1, t_1 \) some symbols which satisfy:

\[
(t'_1 + 1)(t'_1 - q) = (t_1 + 1)(t_1 - q) = 0.
\]  

(A.4)

**Lemma A.5.** We have:

\[
(q^{-1}t'_1t_1)^{2-p}t_1st'_1 + (q - 1) \sum_{k=1}^{p-2} (q^{-1}t'_1t_1)^{1-k}st'_1 = (t_1^{-1}t^{-1}_1t^{-1}_1t^{-1}_1 \ldots t^{-1}_1t^{-1}_1t_1t_1)_{\text{p-2 factors}}.
\]  

p-2 factors
Proof. For \( p = 2 \) we get:

\[
t_1 s'_1 = t_1 s'_1,
\]

which is obviously true. If the equality is satisfied for \( p - 1 \geq 2 \), we get:

\[
(q^{-1}t'_1t_1)^{2-p}t_1s'_1 + (q - 1)\sum_{k=1}^{p-2} (q^{-1}t'_1t_1)^{1-k}s'_1
\]

\[
= (q^{-1}t'_1t_1)^{2-p}t_1s'_1 + (q - 1)\sum_{k=2}^{p-2} (q^{-1}t'_1t_1)^{1-k}s'_1 + (q - 1)s'_1
\]

\[
= (q^{-1}t'_1t_1)^{-1}(q^{-1}t'_1t_1)^{3-p}t_1s'_1 + (q - 1)(q^{-1}t'_1t_1)^{-1}\sum_{k=1}^{p-3} (q^{-1}t'_1t_1)^{1-k}s'_1 + (q - 1)s'_1
\]

\[
= (q^{-1}t'_1t_1)^{-1}\left[(q^{-1}t'_1t_1)^{2-(p-1)}t_1s'_1 + (q - 1)\sum_{k=1}^{p-2} (q^{-1}t'_1t_1)^{1-k}s'_1\right] + (q - 1)s'_1
\]

\[
= q(t_1^{-1}t'_1^{-1} \ldots t_1^{-1}t_1) t_1s'_1 + (q - 1)s'_1
\]

\[
= (t_1^{-1}t'_1^{-1} \ldots t_1^{-1}t_1) t_1s'_1 - (q - 1)(t_1^{-1}t'_1^{-1} \ldots t_1^{-1}t_1) t_1s'_1 + (q - 1)s'_1
\]

\[
= (t_1^{-1}t'_1^{-1} \ldots t_1^{-1}) (t_1t'_1 \ldots t_1t_1') t_1s'_1 - (q - 1)t_1^{-1}t_1s'_1 + (q - 1)s'_1
\]

\[
= q(t_1^{-1}t'_1^{-1} \ldots t_1^{-1}) (t_1t'_1 \ldots t_1t_1') t_1s'_1
\]

thus we are done. If \( p \) is odd, similarly we obtain, now using \( qt_1^{-1} = t'_1 - (q - 1) \):

\[
(q^{-1}t'_1t_1)^{2-p}t_1s'_1 + (q - 1)\sum_{k=1}^{p-2} (q^{-1}t'_1t_1)^{1-k}s'_1
\]

\[
= q(t_1^{-1}t'_1^{-1} \ldots t_1^{-1}t_1) (t_1t'_1 \ldots t_1t_1') t_1s'_1 + (q - 1)s'_1
\]

\[
= (t_1^{-1}t'_1^{-1} \ldots t_1^{-1}) t_1s'_1 - (q - 1)(t_1^{-1}t'_1^{-1} \ldots t_1^{-1}) (t_1t'_1 \ldots t_1t_1') t_1s'_1 + (q - 1)s'_1
\]

\[
= (t_1^{-1}t'_1^{-1} \ldots t_1^{-1}) (t_1t'_1 \ldots t_1t_1') t_1s'_1 - (q - 1)t_1^{-1}t_1s'_1 + (q - 1)s'_1
\]

\[
= (t_1^{-1}t'_1^{-1} \ldots t_1^{-1}) (t_1t'_1 \ldots t_1t_1') t_1s'_1
\]

\[
= (t_1^{-1}t'_1^{-1} \ldots t_1^{-1}) (t_1t'_1 \ldots t_1t_1') t_1s'_1 - (q - 1)t_1^{-1}t_1s'_1 + (q - 1)s'_1
\]
\[= (t_1^{-1} t_1' \cdots t_1^{-1}) (t_1' t_1 t_1' \cdots t_1') t_1 s t_1',\]

thus we are done. \qed

**Proposition A.6.** We assume that \( s, t_1', t_1 \) satisfy, in addition to (A.4), the following relation:

\[ st_1' t_1 = t_1' t_1 s. \tag{A.7} \]

The relations:

\[ st_1' t_1 = (q^{-1} t_1' t_1)^2 - p t_1 s t_1' + (q - 1) \sum_{k=1}^{p-2} (q^{-1} t_1' t_1)^{1-k} s t_1', \tag{Ar} \]

and:

\[ st_1' t_1 \cdots = t_1 s t_1' \cdots, \tag{BMR} \]

are equivalent.

**Proof.** By Lemma A.5, relation (Ar) is equivalent to:

\[ st_1' t_1 = (t_1^{-1} t_1^{-1} t_1^{-1} \cdots) (t_1' t_1 t_1' \cdots) t_1 s t_1'. \tag{A.8} \]

If \( p \) is even, this reads:

\[ st_1' t_1 = (t_1^{-1} t_1^{-1} \cdots t_1^{-1}) (t_1' t_1 t_1' \cdots) t_1 s t_1', \]

whence we obtain:

\[ t_1' t_1 \cdots t_1' t_1 s t_1' = t_1 t_1' \cdots t_1' t_1 s t_1'. \]

Thus, using (A.7) to bring \( s \) to the left on both sides, we get:

\[ st_1' t_1 \cdots = t_1 s t_1' \cdots, \]

which is the desired result: the relations (Ar) and (BMR) are equivalent. If now \( p \) is odd, relation (A.8) reads:

\[ st_1' t_1 = (t_1^{-1} t_1^{-1} \cdots t_1^{-1}) (t_1' t_1 t_1' \cdots) t_1 s t_1', \]

whence we obtain:

\[ t_1 t_1' \cdots t_1' t_1 s t_1' = t_1' t_1 \cdots t_1' t_1 s t_1'. \]

Thus, using (A.7) to bring \( s \) to the left on both sides, we get:

\[ t_1 s t_1' \cdots = s t_1' \cdots, \]

which is the desired result: the relations (Ar) and (BMR) are thus equivalent. \qed

Using Proposition A.6, it is now clear that the algebra \( H_{p,n}^A(q) \) is isomorphic to the one defined by Ariki in [Ar95] as stated in Remark 1.16.
