This work has been supported by the ANR-14-CE25-0006 project of the French National  
Research Agency.

We define an equivalence relation on subdivided stars \( \sim_2 \). Let \( S \) and \( S' \) be two subdivided stars. We say  
that \( S \) and \( S' \) are \( \sim_2 \)-equivalent, denoted \( S \sim_2 S' \), if and only if for any subdivided star \( \hat{S} \), \( S \sim_2 \hat{S} \equiv S' \sim_2 \hat{S} \).  
By Lemma 17 in [1], we already know that \( P_1 \sim_2 \emptyset \), and thus \( S_2 \sim_2 \emptyset \) and \( S_1,1 \sim_2 \emptyset \).  
We will prove that there are exactly ten equivalence classes for \( \sim_2 \):

- \( D_0^* \): subdivided stars \( S \) such that \( G(S) = 0 \) and \( S \) contains zero or two paths of length 2, plus \( S_2 \);
- \( D_1^* = \{ P_1, S_{2,1}, S_{2,2,2} \} \) (these stars have Grundy value 1);
- \( D_2^* \): subdivided stars \( S \) such that \( G(S) = 1 \), \( S \) contains zero or two paths of length 2 and \( S \neq P_1 \);
- \( D_2^0 = \{ P_2, S_{2,2} \} \) (these stars have Grundy value 2);
- \( D_3^* \): subdivided stars \( S \) such that \( G(S) = 2 \) and \( S \) contains one or three paths of length 2;
- \( D_3^0 \): subdivided stars \( S \) such that \( G(S) = 3 \) and \( S \) contains one or three paths of length 2;
- For \( i \in \{0, 1, 2, 3\} \), \( D_i \): subdivided stars \( S \) with \( G(S) = i \) and \( S \) is not in a previous class.

Figure 1 shows the equivalence classes of the subdivided stars.

**Theorem 22.** The equivalence classes for \( \sim_2 \) are exactly the sets \( D_0, D_0^*, D_1, D_1^*, D_2, D_2^*, D_3, D_3^0 \) and \( D_3^0 \). Moreover, Table 1 describes how the Grundy value of \( S \sim_2 S' \) can be computed depending on the equivalence class of \( S \) and \( S' \).

**Proof.** We prove by induction on the total number of vertices in \( S \) and \( S' \) that the Grundy value of \( S \sim_2 S' \) is given by Table 1.  

One can check that the rows and columns for \( D_1^* \) and \( D_2^0 \) in Table 1 are correct: it suffices to prove it for one representant for \( D_1^* \) (say \( P_1 \)) and for \( D_2^0 \) (say \( P_2 \)). Indeed, Lemma 23 in [1] proves that \( S \sim_2 S' \) if \( S, S' \in D_1^* \) or \( S, S' \in D_2^0 \). For any subdivided star \( \hat{S} \), \( \hat{S} \sim_2 P_1 \) is \( \hat{S} \) with a path of length 2 attached to its central vertex. Thus, for every class, we only need to look at the value diagonally to the right and below in Figure 1. One can check that if \( G(\hat{S}) = 0 \), then \( G(\hat{S} \sim_2 P_1) = 2 \), if \( \hat{S} \in D_1^*, D_2^0, D_3^0 \), then \( G(\hat{S} \sim_2 P_1) = 0 \), if \( \hat{S} \in D_1^*, D_2^0 \), then \( G(\hat{S} \sim_2 P_1) = 3 \), if \( \hat{S} \in D_2^0, D_3^0, D_3 \), then \( G(\hat{S} \sim_2 P_1) = 1 \). For any subdivided star \( \hat{S} \), \( \hat{S} \sim_2 P_2 \) is \( \hat{S} \) with a path of length 3 attached to its central vertex. Thus, \( G(\hat{S} \sim_2 P_2) = G(\hat{S}) \).

Now we study the Grundy value of \( S \sim_2 S' \) depending on the class of \( S \) and \( S' \). We can suppose that \( S, S' \notin D_1^*, D_2^0 \), and that neither \( S \) nor \( S' \) are \( S_{1,1} \) or \( P_3 \) (since \( S_{1,1} \sim_2 \emptyset \); and \( P_3 \sim_2 \emptyset \)). We can find the
Number of paths of length 2 in the subdivided star

</table>

Table 1: Computing the Grundy value of \( S \mapsto S' \) depending on the equivalence class of \( S \) and \( S' \). Recall that \( \oplus \) denotes the nim-sum. Moreover, \( x \oplus_1 y \) stands for \( x \oplus y \oplus 1 \).

Grundy values of the options of \( S \) and \( S' \) thanks to Figure 1. None of the options of \( S \) and \( S' \) involves taking their central vertex. We can verify Table 1 by computing the Grundy value of \( S \mapsto S' \) depending on the Grundy values of their options, by using the induction hypothesis:
\[ G(S \rightarrow S') = \text{mex}(G(T \rightarrow S'), G(S \rightarrow T')) | T \text{ option of } S, T' \text{ option of } S' \]

In order to prove that the equivalence classes are correct, we need to check that the Grundy value of \( S \rightarrow S' \) does not change with the classes of the options of \( S \) and \( S' \). Indeed, two subdivided stars belonging to the same class can have different options.

There is a total of 36 cases to consider, which is why the full proof was not included in [1]. Indeed, all those cases work the exact same way: we verify that for each class of each possible option of \( S \) and \( S' \), the \text{mex} value of those options is what is predicted by Table 1. The notation \( D_i \rightarrow D_j \) expresses the fact that the two subdivided stars \( S \) and \( S' \) are in the classes \( D_i \) and \( D_j \) respectively. Furthermore, on figures, the original \( S \rightarrow S' \) will be boxed while the options obtained when playing on \( S \) will be displayed on the left, and those obtained when playing on \( S' \) will be displayed on the right (if \( S \) and \( S' \) are in the same class, then we will display them on only one side). Below each option will be the Grundy value predicted by Table 1 (we can apply the induction hypothesis on the options since they have strictly less vertices than \( S \rightarrow S' \)).

**Case 1:** \( S, S' \in D_0^* \)

Figure 2 depicts all possible options, their Grundy values and show that the \text{mex} computation always leads to 1 for every set of options. Thus, \( G(S \rightarrow S') = 1 \), which is what is predicted by Table 1.

**Case 2:** \( S \in D_0^* \) and \( S' \in D_1^* \)

Figure 3 depicts all possible options, their Grundy values and show that the \text{mex} computation always leads to 0 for every set of options. Thus, \( G(S \rightarrow S') = 0 \), which is what is what is predicted by Table 1.

**Case 3:** \( S \in D_0^* \) and \( S' \in D_2^* \)

Figure 4 depicts all possible options, their Grundy values and show that the \text{mex} computations of the right options always leads to 3, while the left options are always at most 3 and as such the computation of any left option with every right option will always yield 3. Thus, \( G(S \rightarrow S') = 3 \), which is what is predicted by Table 1.

**Case 4:** \( S \in D_0^* \) and \( S' \in D_3^* \)

Figure 5 depicts all possible options, their Grundy values and show that the mex computations of the right options always leads to 2, while the left options are always at most 2 and as such the computation of...
any left option with every right option will always yield 2. Thus, \( G(S \leftrightarrow S') = 2 \), which is what is predicted by Table 1.

**Case 5:** \( S \in D_0^* \) and \( S' \in D_0 \)

Figure 6 depicts all possible options, their Grundy values and show that the \( \text{mex} \) computations of the left options always leads to 1, while the right options are always at most 1 and as such the computation of any left option with every right option will always yield 1. Thus, \( G(S \leftrightarrow S') = 1 \), which is what is predicted by Table 1.

**Case 6:** \( S \in D_0^* \) and \( S' \in D_1 \)

Figure 7 depicts all possible options, their Grundy values and show that the \( \text{mex} \) computations of every set of options always leads to 0. Thus, \( G(S \leftrightarrow S') = 0 \), which is what is predicted by Table 1.
Case 7: $S \in D_0^*$ and $S' \in D_2$

Figure 5 depicts all possible options, their Grundy values and show that the computation of any left option with every right option will always yield 3. Thus, $G(S \triangleright S') = 3$, which is what is predicted by Table 1.

Case 8: $S \in D_0^*$ and $S' \in D_3$

Figure 6 depicts all possible options, their Grundy values and show that the mex computations of the right options always leads to 2, while the left options are always at most 2 and as such the computation of any left option with every right option will always yield 2. Thus, $G(S \triangleright S') = 2$, which is what is predicted by Table 1.

Case 9: $S, S' \in D_1$

Case 7: $S \in D_0^*$ and $S' \in D_2$

Figure 5 depicts all possible options, their Grundy values and show that the computation of any left option with every right option will always yield 3. Thus, $G(S \triangleright S') = 3$, which is what is predicted by Table 1.

Case 8: $S \in D_0^*$ and $S' \in D_3$

Figure 6 depicts all possible options, their Grundy values and show that the mex computations of the right options always leads to 2, while the left options are always at most 2 and as such the computation of any left option with every right option will always yield 2. Thus, $G(S \triangleright S') = 2$, which is what is predicted by Table 1.

Case 9: $S, S' \in D_1$
Figure 7: Possible options for the case $S \in D_0^*$ and $S' \in D_1$.

Figure 8: Possible options for the case $S \in D_0^*$ and $S' \in D_2$.

Figure 10 depicts all possible options, their Grundy values and show that the mex computation always leads to 1 for every set of options. Thus, $G(S \xrightarrow{\cdot} S') = 1$, which is what is predicted by Table 1.

**Case 10:** $S \in D_1^2$ and $S' \in D_2^2$

Figure 11 depicts all possible options, their Grundy values and show that the mex computation of the right options always leads to 2, while the left options are always at most 2 and as such the computation of any left option with every right option will always yield 2. Thus, $G(S \xrightarrow{\cdot} S') = 2$, which is what is predicted by Table 1.

**Case 11:** $S \in D_1^2$ and $S' \in D_3^2$

Figure 12 depicts all possible options, their Grundy values and show that the mex computation of the right options always leads to 3, while the left options are always at most 3 and as such the computation of
any left option with every right option will always yield 3. Thus, $G(S \rightarrow S') = 3$, which is what is predicted by Table 1.

**Case 12:** $S \in D_0^1$ and $S' \in D_0$

Figure 9 depicts all possible options, their Grundy values and show that the mex computation always leads to 0. Thus, $G(S \rightarrow S') = 0$, which is what is predicted by Table 1.

**Case 13:** $S \in D_1^0$ and $S' \in D_1$

Figure 10 depicts all possible options, their Grundy values and show that the mex computation always leads to 1. Thus, $G(S \rightarrow S') = 1$, which is what is predicted by Table 1.
Case 14: $S \in D_1^2$ and $S' \in D_2$

Figure 15 depicts all possible options, their Grundy values and show that the mex computation of the right options always leads to 2, while the left options are always at most 2, and as such the computations of any left option with every right option will always yield 2. Thus, $G(S \rightarrow S') = 2$, which is what is predicted by Table 1.

Case 15: $S \in D_1^2$ and $S' \in D_3$

Figure 16 depicts all possible options, their Grundy values and show that the mex computation of the right options always leads to 3, while the left options are always at most 3, and as such the computations of any left option with every right option will always yield 3. Thus, $G(S \rightarrow S') = 3$, which is what is predicted by Table 1.

Case 16: $S, S' \in D_2^2$
Figure 15: Possible options for the case $S \in D_1^2$ and $S' \in D_2$.

Figure 16: Possible options for the case $S \in D_1^2$ and $S' \in D_3$.

Figure 17: Possible options for the case $S, S' \in D_2^2$.

Case 17: $S \in D_2^2$ and $S' \in D_2^2$

Case 18: $S \in D_2^2$ and $S' \in D_0$

Case 19: $S \in D_2^2$ and $S' \in D_1$

Case 20: $S \in D_2^2$ and $S' \in D_2$
any left option with every right options will always yield 1. Thus, $G(S \rightarrow S') = 1$, which is what is predicted by Table 1.

**Case 21:** $S \in D_2^3$ and $S' \in D_3^3$

Figure 22 depicts all possible options, their Grundy values and show that the mex computation always leads to 0. Thus, $G(S \rightarrow S') = 0$, which is what is predicted by Table 1.

**Case 22:** $S, S' \in D_2^3$

Figure 23 depicts all possible options, their Grundy values and show that the mex computation always leads to 1 for every set of options. Thus, $G(S \rightarrow S') = 1$, which is what is predicted by Table 1.

**Case 23:** $S \in D_2^3$ and $S' \in D_0^3$

Figure 24 depicts all possible options, their Grundy values and show that the mex computation always leads to 2. Thus, $G(S \rightarrow S') = 2$, which is what is predicted by Table 1.
Case 24: $S \in D_{3}^{2}$ and $S' \in D_{1}$

Figure 25 depicts all possible options, their Grundy values and show that the mex computation always leads to 3. Thus, $\mathcal{G}(S \rightarrow^* S') = 3$, which is what is predicted by Table [ ]
Figure 25: Possible options for the case $S \in D_3^0$ and $S' \in D_1$.

**Case 25:** $S \in D_3^0$ and $S' \in D_2$
