Abstract

We study the problem of an elastic inclusion with high rigidity in a 3D domain. First we consider an inclusion with a plate-like geometry and then in the more general framework of curvilinear coordinates, an inclusion with a shell-like geometry. We compare our formal models to those obtained by Chapelle-Ferent and by Bessoud et al..

Résumé

Inclusions élastiques de grande rigidité de type plaque ou coque On étudie le problème d'une inclusion élastique de grande rigidité dans un domaine 3D. Cette inclusion est d'abord vue comme un domaine géométrique de type plaque, puis plus généralement comme un domaine géométrique de type coque. On compare les modèles obtenus formellement à ceux de Chapelle-Ferent et de Bessoud et al.. *Pour citer cet article : A.L. Bessoud, F. Krasucki, M. Serpilli, C. R. Acad. Sci. Paris*

1. Introduction

After the pioneering works of Pham Huy-Sanchez [1], Brezis et al [2] and Caillerie [3], the thin inclusion of a third material between two other ones when the rigidity properties of the inclusion are highly contrasted with respect to those of the surrounding material has been deeply investigated. More recently, Chapelle-Ferent [4] in order to justify some methods used in FEM approximation have studied the asymptotic behavior of a shell-like inclusion of $\frac{1}{\varepsilon^p}$ -rigidity ($p = 1$ or $p = 3$) in a 3D domain. In a slightly different geometrical and mechanical context, Bessoud et al. [5] have studied the behavior of a ε -thin 3D layer of

$\frac{1}{\varepsilon}$ -rigidity. More precisely, they assume that the thin layer can be written as $\omega \times]-\varepsilon, \varepsilon[$ where ω is a projectable 2D surface, and that all the materials are linearly elastic anisotropic. Then the limit problem is a Ventcel-type transmission problem between two 3D linearly elastic anisotropic bodies. When ω is planar and in the isotropic case, the associated surface energy term can be interpreted as the membranal energy of a Kirchhoff-Love plate.

Here two situations are considered using a two fields approach analogous to [4]. In section 2 we study the same geometrical situation as in [5] when the material in the thin layer is isotropic and with a $\frac{1}{\varepsilon^p}$ -rigidity ($p = 1$ or $p = 3$). When $p = 3$, in the formal limit problem the associated surface energy corresponds to a flexural energy for a Kirchhoff-Love plate. When $p = 1$, the associated surface energy corresponds to the membranal energy of [5].

In section 3 we study a new situation where the shell-like thin layer is obtained by the translation in the normal direction of a general 2D surface, see (2). Using a system of curvilinear coordinates we deduce the formal limit problem for the two cases $p = 1$ and $p = 3$. In this way we obtain the same limit problems as in [4], also if the kinematical assumptions for the physical problem are not the same. Indeed in [4] the authors a priori assume a shell-like energy in the thin layer. As in [4] one must stress that the well-posedness of the limit problems is essentially linked to the well-posedness of the shell models [6],[7],[8].

2. Plate-like inclusion: asymptotic behavior

In the three-dimensional Euclidean space $\mathcal{E}^3$ referred to the Cartesian coordinate frame $(O; \mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3)$, let Ω^+ and Ω^- be two disjoint open domains with smooth boundaries $\partial\Omega^+$ and $\partial\Omega^-$. Let $\omega = \{\partial\Omega^+ \cap \partial\Omega^-\}^\circ$, which is assumed to be a domain in $\mathbb{R}^2$ having a positive two-dimensional measure and let $y = (y_\alpha)$ denote a generic point of $\bar{\omega}$. We insert the intermediate layer moving Ω^+ , (resp. Ω^-) in the $\mathbf{e}_3$ (resp. $-\mathbf{e}_3$) direction of an amount equal to $\varepsilon > 0$, a small dimensionless real parameter. Then let $\Omega^{\pm, \varepsilon} := \{x^\varepsilon := x \pm \varepsilon \mathbf{e}_3; x \in \Omega^\pm\}$, $\Omega^{m, \varepsilon} := \omega \times]-\varepsilon, \varepsilon[$, and $\Omega^\varepsilon := \Omega^{-, \varepsilon} \cup \Omega^{+, \varepsilon} \cup \Omega^{m, \varepsilon}$. The structure is clamped on $\Gamma_0 \subset (\partial\Omega^\varepsilon \setminus \Gamma^{m, \varepsilon})$ and $\Gamma^{m, \varepsilon} := \partial\omega \times]-\varepsilon, \varepsilon[$ is traction free. We suppose that the materials occupying Ω^ε are linearly elastic and isotropic. Let

$$V^\varepsilon = \{(\mathbf{V}, \mathbf{v}) \in H^1(\Omega^\varepsilon; \mathbb{R}^3) \times H^1(\Omega^{m, \varepsilon}; \mathbb{R}^3); \mathbf{V}|_{\Omega^{m, \varepsilon}} = \mathbf{v}; \mathbf{V}|_{\Gamma_0} = 0\}.$$

The physical variational problem defined over the variable domain Ω^ε can be written as

$$\begin{cases} \text{Find } (\mathbf{U}^\varepsilon, \mathbf{u}^\varepsilon) \in V^\varepsilon \text{ such that for all } (\mathbf{V}, \mathbf{v}) \in V^\varepsilon \\ A^{-, \varepsilon}(\mathbf{U}^\varepsilon, \mathbf{V}^\varepsilon) + A^{+, \varepsilon}(\mathbf{U}^\varepsilon, \mathbf{V}^\varepsilon) + A^{m, \varepsilon}(\mathbf{u}^\varepsilon, \mathbf{v}^\varepsilon) = L(\mathbf{V}), \end{cases} \quad (1)$$

where

$$\begin{aligned} A^{\pm, \varepsilon}(\mathbf{U}^\varepsilon, \mathbf{V}^\varepsilon) &= \int_{\Omega^{\pm, \varepsilon}} (\lambda^{\pm, \varepsilon} e_{pp}^\varepsilon(\mathbf{U}^\varepsilon) e_{qq}^\varepsilon(\mathbf{V}^\varepsilon) + 2\mu^{\pm, \varepsilon} e_{ij}^\varepsilon(\mathbf{U}^\varepsilon) e_{ij}^\varepsilon(\mathbf{V}^\varepsilon)) dx^\varepsilon, \\ A^{m, \varepsilon}(\mathbf{u}^\varepsilon, \mathbf{v}^\varepsilon) &= \int_{\Omega^{m, \varepsilon}} (\lambda^{m, \varepsilon} e_{pp}^\varepsilon(\mathbf{u}^\varepsilon) e_{qq}^\varepsilon(\mathbf{v}^\varepsilon) + 2\mu^{m, \varepsilon} e_{ij}^\varepsilon(\mathbf{u}^\varepsilon) e_{ij}^\varepsilon(\mathbf{v}^\varepsilon)) dx^\varepsilon. \end{aligned}$$

The functional $L(\cdot)$ is the linear application associated with the applied forces.

Let us suppose that the Lamé's constants of the isotropic materials satisfy

$$\lambda^{\pm, \varepsilon} = \lambda^\pm, \quad \mu^{\pm, \varepsilon} = \mu^\pm, \quad \lambda^{m, \varepsilon} = \frac{1}{\varepsilon^p} \lambda^m, \quad \mu^{m, \varepsilon} = \frac{1}{\varepsilon^p} \mu^m,$$

where $p \in \{1, 3\}$, and $\lambda^\pm$, λ^m (resp. $\mu^\pm$, and μ^m) are of the same order of magnitude.

In order to study the asymptotic behavior of the solution of the physical problem (1) when ε tends to zero, we apply the usual change of variable (see [9]), which transforms the problem posed on a ε -dependent domain into a problem over the fixed domain $\Omega := \Omega^{\pm,1} \cup \Omega^m$, where $\Omega^m := \omega \times]-1, 1[$ is the rescaled domain of $\Omega^{m,\varepsilon}$. The rescaled problem assumes the following form, with $V = \{(\mathbf{V}, \mathbf{v}) \in H^1(\Omega; \mathbb{R}^3) \times H^1(\Omega^m; \mathbb{R}^3); \mathbf{V}|_{\Omega^m} = \mathbf{v}; \mathbf{V}|_{\Gamma_0} = 0\}$:

$$\begin{cases} \text{Find } (\mathbf{U}(\varepsilon), \mathbf{u}(\varepsilon)) \in V \text{ such that for all } (\mathbf{V}, \mathbf{v}) \in V \\ A^-(\mathbf{U}(\varepsilon), \mathbf{V}) + A^+(\mathbf{U}(\varepsilon), \mathbf{V}) + \frac{1}{\varepsilon^{p-1}} A_{\alpha\beta}^m(\mathbf{u}(\varepsilon), \mathbf{v}) + \frac{1}{\varepsilon^p} A_{\alpha 3}^m(\mathbf{u}(\varepsilon), \mathbf{v}) + \frac{1}{\varepsilon^{p+1}} A_{33}^m(\mathbf{u}(\varepsilon), \mathbf{v}) = L(\mathbf{V}), \end{cases}$$

where $A^\pm(\cdot, \cdot)$ is the natural bilinear form on $\Omega^\pm$, and the bilinear forms $A_{ij}^m(\cdot, \cdot)$ are defined as follows:

$$\begin{aligned} A_{\alpha\beta}^m(\mathbf{u}, \mathbf{v}) &= \int_{\Omega^m} \left(\lambda^m e_{\sigma\sigma}(\mathbf{u}) e_{\tau\tau}(\mathbf{v}) + 2\mu^m e_{\alpha\beta}(\mathbf{u}) e_{\alpha\beta}(\mathbf{v}) + \frac{\mu^m}{2} \partial_\alpha u_3 \partial_\alpha v_3 \right) dx, \\ A_{\alpha 3}^m(\mathbf{u}, \mathbf{v}) &= \int_{\Omega^m} \left(\frac{\mu^m}{2} (\partial_\alpha u_3 \partial_3 v_\alpha + \partial_3 u_\alpha \partial_\alpha v_3) + \lambda^m (e_{\sigma\sigma}(\mathbf{u}) e_{33}(\mathbf{v}) + e_{33}(\mathbf{u}) e_{\sigma\sigma}(\mathbf{v})) \right) dx, \\ A_{33}^m(\mathbf{u}, \mathbf{v}) &= \int_{\Omega^m} \left((\lambda^m + 2\mu^m) e_{33}(\mathbf{u}) e_{33}(\mathbf{v}) + \frac{\mu^m}{2} \partial_3 u_\alpha \partial_3 v_\alpha \right) dx. \end{aligned}$$

We look for the following formal *a priori* asymptotic expansion of the solution $(\mathbf{U}(\varepsilon), \mathbf{u}(\varepsilon))$:

$$\mathbf{U}(\varepsilon) = \mathbf{U}^0 + \varepsilon \mathbf{U}^1 + \varepsilon^2 \mathbf{U}^2 + \dots, \quad \mathbf{u}(\varepsilon) = \mathbf{u}^0 + \varepsilon \mathbf{u}^1 + \varepsilon^2 \mathbf{u}^2 + \dots$$

The leading terms $(\mathbf{U}^0, \mathbf{u}^0)$ of the asymptotic expansion satisfy the limit problems:

(i) $p = 1$:

$$\begin{cases} \text{Find } (\mathbf{U}^0, \mathbf{u}^0) \in V_M \text{ such that for all } (\mathbf{V}, \mathbf{v}) \in V_M \\ A^-(\mathbf{U}^0, \mathbf{V}) + A^+(\mathbf{U}^0, \mathbf{V}) + A_M^m(\mathbf{u}^0, \mathbf{v}) = L(\mathbf{V}), \end{cases}$$

where

$$\begin{aligned} V_M &= \{(\mathbf{V}, \mathbf{v}) \in H^1(\Omega; \mathbb{R}^3) \times H^1(\omega; \mathbb{R}^3); \mathbf{V}|_\omega = \mathbf{v}, \mathbf{V}|_{\Gamma_0} = 0\}, \\ A_M^m(\mathbf{u}, \mathbf{v}) &= \int_\omega \left(\frac{4\lambda^m \mu^m}{\lambda^m + 2\mu^m} e_{\sigma\sigma}(\mathbf{u}) e_{\tau\tau}(\mathbf{v}) + 4\mu^m e_{\alpha\beta}(\mathbf{u}) e_{\alpha\beta}(\mathbf{v}) \right) dy \end{aligned}$$

is the bilinear form associated with the membrane behavior of the plate.

(ii) $p = 3$:

$$\begin{cases} \text{Find } (\mathbf{U}^0, \mathbf{u}^0) \in V_F \text{ such that for all } (\mathbf{V}, \mathbf{v}) \in V_F \\ A^-(\mathbf{U}^0, \mathbf{V}) + A^+(\mathbf{U}^0, \mathbf{V}) + A_F^m(\mathbf{u}^0, \mathbf{v}) = L(\mathbf{V}), \end{cases}$$

where

$$\begin{aligned} V_F &= \{(\mathbf{V}, \mathbf{v}) \in H^1(\Omega; \mathbb{R}^3) \times H^2(\omega; \mathbb{R}^3); \mathbf{V}|_\omega = \mathbf{v}, \mathbf{V}|_{\Gamma_0} = 0, e_{\alpha\beta}(\mathbf{v}) = 0\}, \\ A_F^m(\mathbf{u}, \mathbf{v}) &= \frac{1}{3} \int_\omega \left(\frac{4\lambda^m \mu^m}{\lambda^m + 2\mu^m} \Delta_\tau u_3 \Delta_\tau v_3 + 4\mu^m \partial_{\alpha\beta} u_3 \partial_{\alpha\beta} v_3 \right) dy \end{aligned}$$

is the bilinear form associated with the flexural behavior of the plate. Δ_τ denotes the two-dimensional Laplacian operator in ω .

Remarks: 1. This problem can be studied in the case of anisotropy of materials and with less restrictive assumptions relative to the geometry of the central layer $\Omega^{m,\varepsilon}$.

2. In the case $p = 1$, the convergence is studied with a slightly different formulation in [5].

3. Shell-like inclusion: asymptotic behavior

Let $\boldsymbol{\theta} \in \mathcal{C}^2(\bar{\omega}; \mathbb{R}^3)$ be an injective mapping such that the vectors $\mathbf{a}_\alpha(y) := \partial_\alpha \boldsymbol{\theta}(y)$ form the covariant basis of the tangent plane to the surface $S := \boldsymbol{\theta}(\bar{\omega})$ at the point $\boldsymbol{\theta}(y)$; the two vectors $\mathbf{a}^\alpha(y)$ of the tangent plane, defined by the relations $\mathbf{a}^\alpha(y) \cdot \mathbf{a}_\beta(y) = \delta_\beta^\alpha$, form its contravariant basis. Also let $\mathbf{a}_3(y) = \mathbf{a}^3(y) := \frac{\mathbf{a}_1(y) \wedge \mathbf{a}_2(y)}{|\mathbf{a}_1(y) \wedge \mathbf{a}_2(y)|}$ be the unit normal vector to S . The covariant and contravariant components $a_{\alpha\beta}$ and $a^{\alpha\beta}$ of the first fundamental form, the covariant and mixed components $b_{\alpha\beta}$ and b_α^β of the second fundamental form, and the Christoffel symbols $\Gamma_{\alpha\beta}^\sigma$ of the surface S are then defined by letting:

$$a_{\alpha\beta} := \mathbf{a}_\alpha \cdot \mathbf{a}_\beta, \quad a^{\alpha\beta} := \mathbf{a}^\alpha \cdot \mathbf{a}^\beta, \quad b_{\alpha\beta} := \mathbf{a}^3 \cdot \partial_\beta \mathbf{a}_\alpha, \quad b_\alpha^\beta := a^{\beta\sigma} b_{\alpha\sigma}, \quad \Gamma_{\alpha\beta}^\sigma := \mathbf{a}^\sigma \cdot \partial_\beta \mathbf{a}_\alpha.$$

Let $\Omega^{m,\varepsilon} := \omega \times]-\varepsilon, \varepsilon[$ be defined as previously, with $\Gamma^{\pm,\varepsilon} := \omega \times \{\pm\varepsilon\}$. Let x^ε denote the generic point in the set $\bar{\Omega}^{m,\varepsilon}$, with $x_\alpha^\varepsilon = y_\alpha$. We consider a shell-like domain with middle surface $S = \boldsymbol{\theta}(\bar{\omega})$ and thickness $2\varepsilon > 0$, whose reference configuration is the image $\boldsymbol{\Theta}^{m,\varepsilon}(\bar{\Omega}^{m,\varepsilon}) \subset \mathbb{R}^3$ of the set $\bar{\Omega}^{m,\varepsilon}$ through the mapping $\boldsymbol{\Theta}^{m,\varepsilon} : \bar{\Omega}^{m,\varepsilon} \rightarrow \mathbb{R}^3$ given by

$$\boldsymbol{\Theta}^{m,\varepsilon}(x^\varepsilon) := \boldsymbol{\theta}(y) + x_3^\varepsilon \mathbf{a}_3(y), \text{ for all } x^\varepsilon = (y, x_3^\varepsilon) = (y_1, y_2, x_3^\varepsilon) \in \bar{\Omega}^{m,\varepsilon}. \quad (2)$$

Moreover, we suppose that there exists an immersion $\boldsymbol{\Theta}^\varepsilon : \bar{\Omega}^\varepsilon \rightarrow \mathbb{R}^3$ defined as follows:

$$\boldsymbol{\Theta}^\varepsilon := \begin{cases} \boldsymbol{\Theta}^{\pm,\varepsilon} & \text{on } \bar{\Omega}^{\pm,\varepsilon} \\ \boldsymbol{\Theta}^{m,\varepsilon} & \text{on } \bar{\Omega}^{m,\varepsilon} \end{cases}, \quad \boldsymbol{\Theta}^{\pm,\varepsilon}(\Gamma^{\pm,\varepsilon}) = \boldsymbol{\Theta}^{m,\varepsilon}(\Gamma^{\pm,\varepsilon}),$$

with $\boldsymbol{\Theta}^{\pm,\varepsilon} : \bar{\Omega}^{\pm,\varepsilon} \rightarrow \mathbb{R}^3$ immersions over $\bar{\Omega}^{\pm,\varepsilon}$ defining the curvilinear coordinates on $\bar{\Omega}^{\pm,\varepsilon}$.

The physical variational problem in these curvilinear coordinates on the variable domain Ω^ε is

$$\begin{cases} \text{Find } (\mathbf{U}^\varepsilon, \mathbf{u}^\varepsilon) \in V^\varepsilon \text{ such that for all } (\mathbf{V}^\varepsilon, \mathbf{v}^\varepsilon) \in V^\varepsilon \\ A^{-,\varepsilon}(\mathbf{U}^\varepsilon, \mathbf{V}^\varepsilon) + A^{+,\varepsilon}(\mathbf{U}^\varepsilon, \mathbf{V}^\varepsilon) + A^{m,\varepsilon}(\mathbf{u}^\varepsilon, \mathbf{v}^\varepsilon) = L(\mathbf{V}^\varepsilon), \end{cases} \quad (3)$$

where

$$\begin{aligned} A^{\pm,\varepsilon}(\mathbf{U}^\varepsilon, \mathbf{V}^\varepsilon) &:= \int_{\Omega^{\pm,\varepsilon}} A_{\pm}^{ijkl,\varepsilon} e_{k\ell}^\varepsilon(\mathbf{U}^\varepsilon) e_{ij}^\varepsilon(\mathbf{V}^\varepsilon) \sqrt{g^{\pm,\varepsilon}} dx^\varepsilon, \\ A^{m,\varepsilon}(\mathbf{u}^\varepsilon, \mathbf{v}^\varepsilon) &:= \int_{\Omega^{m,\varepsilon}} A_m^{ijkl,\varepsilon} e_{k\ell}^\varepsilon(\mathbf{u}^\varepsilon) e_{ij}^\varepsilon(\mathbf{v}^\varepsilon) \sqrt{g^{m,\varepsilon}} dx^\varepsilon. \end{aligned}$$

Here $A^{ijkl,\varepsilon} := \lambda^\varepsilon g^{ij,\varepsilon} g^{kl,\varepsilon} + \mu^\varepsilon (g^{ik,\varepsilon} g^{jl,\varepsilon} + g^{il,\varepsilon} g^{jk,\varepsilon})$ are the contravariant components of the elasticity tensor, $g^\varepsilon := \det(g_{ij}^\varepsilon)$, with $(g_{ij}^\varepsilon) := (\partial_i \boldsymbol{\Theta}^\varepsilon \cdot \partial_j \boldsymbol{\Theta}^\varepsilon)$ and the $(g^{ij,\varepsilon}) := (g_{ij}^\varepsilon)^{-1}$ respectively the covariant and contravariant components of the metric tensor associated with $\boldsymbol{\Theta}^\varepsilon$.

As in the previous section, in order to study the asymptotic behavior of the physical problem (3), we apply the usual change of variable, which transforms Ω^ε into a fixed domain Ω .

Now, the leading terms $(\mathbf{U}^0, \mathbf{u}^0)$ of the asymptotic expansion satisfy the following limit problems:

(i) $p = 1$:

$$\begin{cases} \text{Find } (\mathbf{U}^0, \mathbf{u}^0) \in V_M \text{ such that for all } (\mathbf{V}, \mathbf{v}) \in V_M \\ A^-(\mathbf{U}^0, \mathbf{V}) + A^+(\mathbf{U}^0, \mathbf{V}) + A_M^m(\mathbf{u}^0, \mathbf{v}) = L(\mathbf{V}), \end{cases}$$

where

$$V_M = \{(\mathbf{V}, \mathbf{v}) \in H^1(\Omega; \mathbb{R}^3) \times H^1(\omega; \mathbb{R}^3); \mathbf{V}|_\omega = \mathbf{v}, \mathbf{V}|_{\Gamma_0} = 0\},$$

$$A_M^m(\mathbf{u}, \mathbf{v}) = \int_\omega a^{\alpha\beta\sigma\tau} \gamma_{\sigma\tau}(\mathbf{u}) \gamma_{\alpha\beta}(\mathbf{v}) \sqrt{a} dy$$

is the bilinear form associated with the membrane behavior of the shell, $a^{\alpha\beta\sigma\tau} := \frac{4\lambda^m \mu^m}{\lambda^m + 2\mu^m} a^{\alpha\beta} a^{\sigma\tau} + 2\mu^m (a^{\alpha\sigma} a^{\beta\tau} + a^{\alpha\tau} a^{\beta\sigma})$ are the contravariant components of the elasticity tensor of the shell and $\gamma_{\alpha\beta}(\mathbf{u}) := \frac{1}{2}(\partial_\alpha u_\beta + \partial_\beta u_\alpha) - \Gamma_{\alpha\beta}^\sigma u_\sigma - b_{\alpha\beta} u_3$ are the covariant components of the change of metric tensor.

(ii) $p = 3$:

$$\begin{cases} \text{Find } (\mathbf{U}^0, \mathbf{u}^0) \in V_F \text{ such that for all } (\mathbf{V}, \mathbf{v}) \in V_F \\ A^-(\mathbf{U}^0, \mathbf{V}) + A^+(\mathbf{U}^0, \mathbf{V}) + A_F^m(\mathbf{u}^0, \mathbf{v}) = L(\mathbf{V}), \end{cases}$$

where

$$V_F = \{(\mathbf{V}, \mathbf{v}) \in H^1(\Omega; \mathbb{R}^3) \times H^2(\omega; \mathbb{R}^3); \mathbf{V}|_\omega = \mathbf{v}, \mathbf{V}|_{\Gamma_0} = 0, \gamma_{\alpha\beta}(\mathbf{v}) = 0 \text{ in } \omega\},$$

$$A_F^m(\mathbf{u}, \mathbf{v}) = \frac{1}{3} \int_\omega a^{\alpha\beta\sigma\tau} \rho_{\sigma\tau}(\mathbf{u}) \rho_{\alpha\beta}(\mathbf{v}) \sqrt{a} \, dy$$

is the bilinear form associated with the flexural behavior of the shell and $\rho_{\alpha\beta}(\mathbf{u}) := \partial_{\alpha\beta} u_3 - \Gamma_{\alpha\beta}^\sigma \partial_\sigma u_3 - b_{\alpha\beta} u_3 + b_\alpha^\sigma (\partial_\beta u_\sigma - \Gamma_{\beta\sigma}^\tau u_\tau) + b_\beta^\tau (\partial_\alpha u_\tau - \Gamma_{\alpha\tau}^\sigma u_\sigma) + (\partial_\alpha b_\beta^\tau + \Gamma_{\alpha\sigma}^\tau b_\beta^\sigma - \Gamma_{\alpha\beta}^\sigma b_\sigma^\tau) u_\tau$ are the covariant components of the change of curvature tensor.

Remark: As in [4] the well-posedness of the limit problems (i) and (ii) depends both on the Hilbertian character of V_M and V_F , and the coerciveness of the bilinear form A_M^m . For the well-posedness of the flexural shell model see [10], [11] and for the well posedness of the membrane shell model see [12], [13].
