Finite mean field games: fictitious play and convergence to a first order continuous mean field game

Saeed Hadikhanloo∗ Francisco J. Silva†

Abstract

In this article we consider finite Mean Field Games (MFGs), i.e. with finite time and finite states. We adopt the framework introduced in [16] and study two seemingly unexplored subjects. In the first one, we analyze the convergence of the fictitious play learning procedure, inspired by the results in continuous MFGs (see [12] and [20]). In the second one, we consider the relation of some finite MFGs and continuous first order MFGs. Namely, given a continuous first order MFG problem and a sequence of refined space/time grids, we construct a sequence finite MFGs whose solutions admit limit points and every such limit point solves the continuous first order MFG problem.

Keywords: Mean field games, finite time and finite state space, fictitious play, first order systems.

1 Introduction

Mean Field Games (MFGs) were introduced by Lasry and Lions in [22, 23, 24] and, independently, by Huang, Caines and Malhamé in [21]. One of the main purposes of the theory is to develop a notion of Nash equilibria for dynamic games, which can be deterministic or stochastic, with an infinite number of players. More precisely, if we consider a $N$-player game and we assume that the players are indistinguishable and small, in the sense that a change of strategy of player $j$ has a small impact on the cost for player $i$, then, under some assumptions, it is possible to show that as $N\to\infty$ the sequence of equilibria admits limit points (see [11]). The latter correspond to probability measures on the set of actions and define the notion of equilibria with a continuum of agents. An interesting feature of the theory is that it allows to obtain important qualitative information on the equilibria and the resulting problem is amenable to numerical computation. We refer the reader to the lessons by P.-L. Lions [25] and to [9, 19, 18, 17] for surveys on the theory and its applications.

Most of the literature about MFGs deals with games in continuous time and where the agents are distributed on a continuum of states (see [9]). In this article we consider a MFG problem where the number of states and times are finite. For the sake of simplicity, we will call finite MFGs the games of this type. This framework has been introduced by Gomes, Mohr and Souza in [16], where the authors prove results related to the existence and uniqueness of equilibria, as well as the convergence to a stationary equilibrium as time goes to infinity.

Our contribution to these type of games is twofold. First, we analyze the fictitious play procedure, which is a learning method for computing Nash equilibria in classical game theory, introduced by Brown in [6]. We refer the reader to [15, Chapter 2] and the references therein for a survey on this subject. Loosely speaking, the idea is that at each iteration, a typical player implements a best response strategy to his belief on the action of the remaining players. The belief at iteration $n \in \mathbb{N}$ is given, by definition, by the average of outputs of decisions of the remaining players in the previous iterations $1, \ldots, n − 1$. In the context of

continuous MFGs, the study of the convergence of such procedure to an equilibrium has been first addressed in [12], for a particular class of MFGs called potential MFGs. This analysis has then been extended in [20], by assuming that the MFG is monotone, which means that agents have aversion to imitate the strategies of other players. Under an analogous monotonicity assumption, we prove in Theorem 4 that the fictitious play procedure converges also in the case of finite MFGs.

Our second contribution concerns the relation between continuous and finite MFGs. We consider here a first order continuous MFG and we associate to it a family of finite MFGs defined on finite space/time grids. By applying the results in [16], we know that for any fixed space/time grid the associated finite MFG admits at least one solution. Moreover, any such solution induces a probability measure on the space of strategies. Letting the grid length tend to zero, we prove that the aforementioned sequence of probability measures is precompact and, hence, has at least one limit point. The main result of this article is given in Theorem 4.1 and asserts that any such limit point is an equilibrium of the continuous MFG problem. To the best of our knowledge, this is the first result relating the equilibria of continuous MFGs, introduced in [24], with the equilibria of finite MFGs, introduced in [16]. Besides the theoretical interest of relating both MFG problems, our result provides an implementable numerical algorithm to solve first order MFGs. Indeed, given a MFG system of this type, with monotone couplings, the sequence of finite MFGs that approximate it admit unique solutions, which can be computed using the fictitious play method presented in Section 3. In this sense, our contribution improves the results in [13], which, to the best of our knowledge, is the only work dealing with a fully-discrete approximation of first order MFGs. In that work, the convergence of a semi-Lagrangian scheme for first order MFGs is shown under the assumption that the state dimension is equal to one, while the convergence result in this article holds true independently of the dimension of the space. Moreover, differently from [13], the fictitious play method provides a convergent procedure to solve rigorously the sequence of approximations of the continuous MFG system.

The article is organized as follows. In Section 2 we recall the finite MFG introduced in [16] and we state our first assumption that ensures the existence of at least one equilibrium. In Section 3 we describe the fictitious play procedure for the finite MFGs and prove its convergence under a monotonicity assumption on the data. In Section 4 we introduce the first order continuous MFG under study, as well as the corresponding space/time discretization and the associated finite MFGs. As the length of the space/time grid tends to zero, we prove several asymptotic properties of the finite MFGs equilibria and we also prove our main result in Theorem 4.1 showing their convergence to a solution of the continuous MFG problem. We end this paper by providing some numerical tests showing how our results can be used in practice to approximate MFG equilibria.

2 The finite state and discrete time Mean Field Game problem

We begin this section by presenting the MFG problem introduced in [16] with finite state and discrete time. Let $\mathcal{S}$ be a finite set, and let $\mathcal{T} = \{0, \ldots, N\}$. We denote by $|\mathcal{S}|$ the number of elements in $\mathcal{S}$, and by

$$\mathcal{P}(\mathcal{S}) := \left\{ m : \mathcal{S} \to [0,1] \mid \sum_{x \in \mathcal{S}} m(x) = 1 \right\},$$

the simplex in $\mathbb{R}^{\mid \mathcal{S}\mid}$, which is identified with the set of probability measures over $\mathcal{S}$. We define now the notion of transition kernel associated to $\mathcal{S}$ and $\mathcal{T}$.
Definition 2.1. We denote by \( K_{S,T} \) the set of all maps \( P : S \times S \times (T \setminus \{N\}) \to [0,1] \), called the transition kernels, such that \( P(x,\cdot,k) \in \mathcal{P}(S) \) for all \( x \in S \) and \( k \in T \setminus \{N\} \).

Note that \( K_{S,T} \) can be seen as a compact subset of \( \mathbb{R}^{|S|^2} \). Given an initial distribution \( M_0 \in \mathcal{P}(S) \) and \( P \in K_{S,T} \), the pair \( (M_0,P) \) induces a probability distribution over \( \mathcal{S}^{N+1} \), with marginal distributions given by

\[
M^0_P(x_0,0) := M_0(x_0), \quad \forall \ x_0 \in S, \\
M^0_P(x_k,k) := \sum_{(x_{k+1},\ldots,x_{k+1}) \in S^k} M_0(x_0) \prod_{k'=0}^{k-1} P(x_{k'},x_{k'+1},t_{k'}) \quad \forall \ k = 1,\ldots,N, \ x_k \in S,
\]

or equivalently, written in a recursively form,

\[
M^0_P(x_0,0) := M_0(x_0), \quad \forall \ x_0 \in S, \\
M^0_P(x_k,k) := \sum_{x_{k-1} \in S} M^0_P(x_{k-1},k-1)P(x_{k-1},x_k,k) \quad \forall \ k = 1,\ldots,N, \ x_k \in S.
\]

Now, let \( c : S \times S \times \mathcal{P}(S) \times \mathcal{P}(S) \to \mathbb{R}, \ g : S \times \mathcal{P}(S) \to \mathbb{R}, \ M : T \to \mathcal{P}(S) \) and define \( J_M : K_{S,T} \to \mathbb{R} \) as

\[
J_M(P) := \sum_{k=0}^{N-1} \sum_{x,y \in S} M^k_P(x,k)P(x,y,k)c_{xy}(P(x,k),M(k)) + \sum_{x \in S} M^k_P(x,N)g(x,M(N)),
\]

where, for notational convenience, we have set \( c_{xy}(\cdot,\cdot) := c(x,y,\cdot,\cdot) \) and \( P(x,k) := P(x,\cdot,k) \in \mathcal{P}(S) \). We consider the following MFG problem: find \( \hat{P} \in K_{S,T} \) such that

\[
\hat{P} \in \text{argmin}_{P \in K_{S,T}} J_M(P) \quad \text{with} \quad M = M^0_P. \tag{MFG_d}
\]

In order to rewrite \( (\text{MFG}_d) \) in a recursive form (as in [16]), given \( k = 0,\ldots,N-1, \ x \in S \) and \( P \in K_{S,T} \), we define a probability distribution in \( \mathcal{S}^{N-k+1} \) whose marginals are given by

\[
\delta_{x,x_{k+1}} := \delta_{x,x_k}, \quad \forall \ x_k \in S, \\
M^k_P(x_{k+1},k+1) := \sum_{x_{k+1} \in S} M^k_P(x_{k+1},k+1)P(x_{k+1},x_{k+1},k+1) \quad \forall \ k = k+1,\ldots,N, \ x_{k+1} \in S,
\]

where \( \delta_{x,x_k} := 1 \) if \( x = x_k \) and \( \delta_{x,x_k} := 0 \), otherwise. Given \( M : T \to \mathcal{P}(S) \), we also set

\[
J^k_M(P) := \sum_{k'=k}^{N-1} \sum_{x,y \in S} M^k_P(x_{k'},k')P(x,y,k')c_{xy}(P(x,k'),M(k')) + \sum_{x \in S} M^k_P(x,N)g(x,M(N))
\]

\[
= \sum_{y \in S} P(x,y,k) \left( c_{xy}(P(x,k),M(k)) + J^{y+1}_M(P) \right).
\]

Since for every \( M : T \to \mathcal{P}(S) \) the function

\[
U_M(x,k) := \inf_{P \in K_{S,T}} J^k_M(P) \quad \forall \ k = 0,\ldots,N-1, \ x \in S, \quad U_M(x,N) := g(x,M(N)), \quad \forall \ x \in S,
\]

satisfies the Dynamic Programming Principle (DPP),

\[
U_M(x,k) = \inf_{P \in \mathcal{P}(S)} \sum_{y \in S} p(y) \left[ c_{xy}(P(x,k),M(k)) + U_M(y,k+1) \right], \quad \forall \ k = 0,\ldots,N-1, \ x \in S, \tag{3}
\]

problem \( (\text{MFG}_d) \) is equivalent to find \( U : S \times T \to \mathbb{R} \) and \( M : T \to \mathcal{P}(S) \) such that

\[
(i) \quad U(x,k) = \sum_{y \in S} \hat{P}(x,y,k) \left[ c_{xy}(\hat{P}(x,k),M(k)) + U(y,k+1) \right], \quad \forall \ k = 0,\ldots,N-1, \ x \in S, \\
(ii) \quad M(y,k-1) \hat{P}(y,x,k-1), \quad \forall \ k = 1,\ldots,N, \ x \in S, \tag{4}
\]

\[
(iii) \quad U(x,N) = g(x,N), \quad M(x,0) = M_0(x) \quad \forall \ x \in S,
\]

\[
3
\]

where \( \hat{P} \in \mathcal{K}_{S,T} \) satisfies
\[
\hat{P}(x,\cdot,k) \in \arg\min_{P \in \mathcal{P}(S)} \sum_{y \in S} p(y) [c_{xy}(p,M(k)) + U(y,k+1)], \quad \forall \ k = 0, \ldots, N-1, \ x \in S. \tag{5}
\]

As in [16], we will assume that

(H1) The following properties hold true:

(i) For every \( x \in S \) the functions \( g(x,\cdot) \) and \( \mathcal{P}(S) \times \mathcal{P}(S) \ni (p,M) \mapsto \sum_{y \in S} p(y)c_{xy}(p,M) \) are continuous.

(ii) For every \( U : S \to \mathbb{R}, \ M \in \mathcal{P}(S) \) and \( x \in S \), the optimization problem
\[
\inf_{p \in \mathcal{P}(S)} \sum_{y \in S} p(y) [c_{xy}(p,M) + U(y)]; \tag{6}
\]

admits a unique solution \( \hat{p}(x,\cdot) \in \mathcal{P}(S) \).

Remark 2.1. (i) By using Brower’s fixed point theorem, it is proved in [16, Theorem 5] that under (H1), problem (MFG) admits at least one solution.

(ii) As a consequence of the DPP, we have that (H1)(ii) implies that for every \( M : T \to \mathcal{P}(S) \), problem
\[
\inf_{P \in \mathcal{K}_{S,T}} J_M(P)
\]

admits a unique solution.

(iii) An example running cost \( c_{xy} \) satisfying that \( \mathcal{P}(S) \times \mathcal{P}(S) \ni (p,M) \mapsto \sum_{y \in S} p(y)c_{xy}(p,M) \) is continuous and (H1)(ii) is given by
\[
c_{xy}(p,M) := K(x,y,M) + \epsilon \log(p(y)) \tag{7}
\]
where \( \epsilon > 0 \), \( K(x,y,\cdot) \) is continuous for all \( x, y \in S \), with the convention that \( 0 \log 0 = 0 \). This type of cost has been already considered in [16], and, given \( x \in S \), the unique solution of (6) is given by
\[
\hat{p}(x,y) = \frac{\exp(-[K(x,y,M) + U(y)]/\epsilon)}{\sum_{y' \in S} \exp(-[K(x,y',M) + U(y')]/\epsilon)}. \tag{8}
\]

In Section 4 we will consider this type of cost in order to approximate continuous MFGs by finite ones.

3 Fictitious play for the finite MFG system

Inspired by the fictitious play procedure introduced for continuous MFGs in [12, 20], we consider in this section the convergence problem for the sequence of functions transition kernels \( P_n \in \mathcal{K}_{S,T} \) and marginal distributions \( M_n : T \to \mathcal{P}(S) \) constructed as follows: given \( M_1 : T \to \mathcal{P}(S) \) arbitrary, set \( M_1 = M_1 \) and, for \( n \geq 1 \), define
\[
P_n := \arg\min_{P \in \mathcal{K}_{S,T}} J_{M_n}(P),
\]
\[
M_{n+1}(\cdot,k) := M_{n}^{M_0}(\cdot,k), \quad \forall \ k = 0, \ldots, N,
\]
\[
M_{n+1}(\cdot,k) := \frac{n}{n+1} M_n(\cdot,k) + \frac{1}{n+1} M_{n+1}(\cdot,k), \quad \forall \ k = 0, \ldots, N,
\tag{9}
\]

where we recall that \( M_0 \) is given and for \( P \in \mathcal{K}_{S,T} \), the function \( M_P^M : S \times T \to [0,1] \) is defined by (1) (or recursively by (2)). Note that by Remark 2.1(ii), the sequences \( (P_n) \) and \( (M_n) \) are well defined under (H1).

The main object of this section is to show that, under suitable conditions, the sequence \( (P_n) \) converges to a solution \( P \) to (MFG) and \( (M_n) \) converges to \( M_0^P \), i.e. the marginal distributions at the equilibrium. In practice, in order to compute \( M_{n+1} \) from \( M_n \), we find first \( P_n \) backwards in time by using the DPP expression for \( U_{M_0} \) in (3) and then we compute \( M_{n+1} \) forward in time by using (2). Notice that both computations are explicit in time.
3.1 Generalized fictitious play

For the sake of simplicity, we present here an abstract framework that will allow us to prove the convergence of the sequence constructed in (9). We begin by introducing some notations that will be also used in Section 4. Let $\mathcal{X}$ and $\mathcal{Y}$ be two Polish spaces and $\Psi : \mathcal{X} \to \mathcal{Y}$ be a Borel measurable function. Given a Borel probability measure $\mu$ on $\mathcal{X}$, we denote by $\Psi_\#\mu$ the probability measure on $\mathcal{Y}$ defined by $\Psi_\#\mu(A) := \mu(\Psi^{-1}(A))$ for all $A \in \mathcal{B}(\mathcal{Y})$. Denoting by $\mathcal{P}(\mathcal{X})$ the set of Borel probability measures on $\mathcal{X}$ and by $d$ the metric on $\mathcal{X}$, we set $\mathcal{P}_p(\mathcal{X})$ for the subset of $\mathcal{P}(\mathcal{X})$ consisting on measures $\mu$ such that $\int_{\mathcal{X}} d(x,x_0)^p d\mu(x) < +\infty$ for some $x_0 \in \mathcal{X}$.

For $\mu_1$, $\mu_2 \in \mathcal{P}_p(\mathcal{X})$ define

$$\Pi(\mu_1, \mu_2) := \{ \mu \in \mathcal{P}(\mathcal{X} \times \mathcal{X}) \mid \pi_1 \#\mu = \mu_1 \text{ and } \pi_2 \#\mu = \mu_2 \},$$

where $\pi_1$, $\pi_2 : \mathcal{X} \times \mathcal{X} \to \mathbb{R}$, are defined by $\pi_i(x_1, x_2) := x_i$ for $i = 1, 2$. Endowed with the Monge-Kantorovic metric

$$d_p(\mu_1, \mu_2) = \inf_{\mu \in \Pi(\mu_1, \mu_2)} \left( \int_{\mathcal{X} \times \mathcal{X}} d(x,y)^p d\mu(x,y) \right)^{1/p},$$

the set $\mathcal{P}_p(\mathcal{X})$ is shown to be a Polish space (see e.g. [1, Proposition 7.1.5]). Let us recall that $d_1$ corresponds to the Kantorovic-Rubinstein metric, i.e.

$$d_1(\mu_1, \mu_2) = \sup \left\{ \int_{\mathcal{X}} f(x) d(\mu_1 - \mu_2)(x) : f \in \text{Lip}_1(\mathbb{R}^d) \right\},$$

(10)

where $\text{Lip}_1(\mathcal{X})$ denotes the set of Lipschitz functions defined in $\mathcal{X}$ with Lipschitz constant less or equal than 1 (see e.g. [20]).

Let $C \subseteq \mathcal{X}$ be a compact set. Then, by definition, $\mathcal{P}(C) = \mathcal{P}_p(C)$ for all $p \geq 1$, and $d_p$ metricizes the weak convergence of probability measures on $C$ (see e.g. [1, Proposition 7.1.5]). Moreover, the set $\mathcal{P}(C)$ is compact.

Now, let $F : C \times \mathcal{P}(C) \to \mathbb{R}$ be a given continuous function. Given $x_1 \in C$ set $\bar{\eta}_1 := \delta_{x_1}$, the Dirac mass at $x_1$, and for $n \geq 1$ define:

$$x_{n+1} \in \arg\min_{x \in C} F(x, \bar{\eta}_n), \quad \bar{\eta}_{n+1} = \frac{1}{n+1} \sum_{k=1}^{n+1} \delta_{x_k} = \frac{n}{n+1} \bar{\eta}_n + \frac{1}{n+1} \delta_{x_{n+1}}.$$  

(11)

We consider now the convergence problem of the sequence $(\bar{\eta}_n)$ to some $\bar{\eta} \in \mathcal{P}(C)$ satisfying that

$$\text{supp}(\bar{\eta}) \subseteq \arg\min_{x \in C} F(x, \bar{\eta}),$$

(12)

where $\text{supp}(\bar{\eta})$ denotes the support of the measure $\bar{\eta}$. We call such $\bar{\eta}$ an equilibrium and its existence can be easily proved by using Fan’s fixed point theorem.

We will prove the convergence of $(\bar{\eta}_n)$ under a monotonicity and unique minimizer condition for $F$.

Definition 3.1 (Monotonicity). The function $F$ is called monotone, if

$$\int_{C} (F(x, \mu_1) - F(x, \mu_2)) d(\mu_1 - \mu_2)(x) \geq 0, \quad \forall \mu_1, \mu_2 \in \mathcal{P}(C), \quad \mu_1 \neq \mu_2.$$  

(13)

Moreover, $F$ is called strictly monotone if the inequality in (13) is strict.

Definition 3.2 (Unique minimizer condition). The function $F$ satisfies the unique minimizer condition if for every $\eta \in \mathcal{P}(C)$ the optimization problem $\inf_{x \in C} F(x, \eta)$ admits a unique solution.

The following remark states some elementary consequence of the previous definitions.
Remark 3.1. (i) If the unique minimizer condition holds then any equilibrium must be a Dirac mass.
Moreover, the application $\mathcal{P}(C) \ni \eta \mapsto x_\eta := \text{argmin}_{x \in C} F(x, \eta) \in C$ is well defined and uniformly continuous.
(ii) If $F$ is monotone and the unique minimizer condition holds then the equilibrium must be unique. Indeed,
suppose that there are two different equilibria $\tilde{\eta} = \delta_{\tilde{z}}$ and $\tilde{\eta}' = \delta_{\tilde{z}'}$. Then, by the unique minimizer condition,
$$F(\tilde{x}, \delta_{\tilde{z}}) < F(\tilde{x}', \delta_{\tilde{z}}), \quad \text{and} \quad F(\tilde{x}', \delta_{\tilde{z}'}) < F(\tilde{x}, \delta_{\tilde{z}'}).$$
This gives $\int_C (F(x, \delta_{\tilde{z}}) - F(x, \delta_{\tilde{z}'}) ) \, d(\delta_{\tilde{z}} - \delta_{\tilde{z}'})(x) < 0$, which contradicts the monotonicity assumption.

Arguing as in [9, Proposition 2.9], it is easy to see that uniqueness of the equilibrium also holds if $F$ is strictly monotone but does not necessarily satisfy the unique minimizer condition.

Theorem 3.1. Assume that

(i) $F$ is monotone and satisfies the unique minimizer condition.

(ii) $F$ is Lipschitz, when $\mathcal{P}(C)$ is endowed with the distance $d_1$, and there exists $C > 0$ such that
$$|F(x_1, \eta_1) - F(x_1, \eta_2) - F(x_2, \eta_1) + F(x_2, \eta_2)| \leq C |x_1 - x_2| d_1(\eta_1, \eta_2),$$
for all $x_1, x_2 \in C$, and $\mu_1, \mu_2 \in \mathcal{P}(C)$

Then, there exists $\tilde{x} \in C$ such that $\tilde{\eta} = \delta_{\tilde{z}}$ is the unique equilibrium and the sequence $(x_n, \tilde{\eta}_n)$ defined by (11) converges to $(\tilde{x}, \delta_{\tilde{z}})$.

Before we prove the theorem, let us recall a preliminary result (see [20]).

Lemma 3.1. Consider a sequence of real numbers $(\phi_n)$ such that $\liminf_{n \to \infty} \phi_n \geq 0$. If there exists a real sequence $(\epsilon_n)$ such that $\lim_{n \to \infty} \epsilon_n = 0$ and
$$\phi_{n+1} - \phi_n \leq -\frac{1}{n+1} \phi_n + \frac{\epsilon_n}{n}, \quad \forall \ n \in \mathbb{N},$$
then $\lim_{n \to \infty} \phi_n = 0$.

Proof. Let $b_n = n \phi_n$ for every $n \in \mathbb{N}$. We have
$$\frac{b_{n+1}}{n+1} - \frac{b_n}{n} \leq -\frac{b_n}{n(n+1)} + \frac{\epsilon_n}{n}, \quad \forall \ n \in \mathbb{N},$$
which implies that $b_{n+1} \leq b_n + (n+1)\epsilon_n/n \leq b_n + 2|\epsilon_n|$. Then, we get $b_n \leq b_1 + 2\sum_{i=1}^{n-1} |\epsilon_i|$ and, hence,
$$0 \leq \liminf_{n \to \infty} \phi_n \leq \limsup_{n \to \infty} \phi_n \leq \lim_{n \to \infty} \frac{b_1 + 2\sum_{i=1}^{n-1} |\epsilon_i|}{n} = 0,$$
from which the result follows.

Proof of Theorem 3.1. Let us define the real sequence $(\phi_n)$ as
$$\phi_n := \int_C F(x, \tilde{\eta}_n) \, d\tilde{\eta}_n(x) - F(x_{n+1}, \tilde{\eta}_n).$$

We claim that $\phi_n \to 0$. Assuming that the claim is true, then any limit point $(\bar{x}, \bar{\eta})$ of $(x_{n+1}, \tilde{\eta}_n)$ satisfies
$$F(\bar{x}, \bar{\eta}) \leq F(x, \bar{\eta}) \quad \forall x \in C, \quad \text{and} \quad F(\bar{x}, \bar{\eta}) = \int_C F(x, \bar{\eta}) \, d\bar{\eta}(x),$$
which implies that $\bar{\eta}$ satisfies (12), i.e. $\bar{\eta}$ is an equilibrium. Using that $F$ is monotone and Remark 3.1(ii), the assertions on the theorem follows.
Thus, it remains to show that \( \phi_n \to 0 \), which will be proved with the help of Lemma 3.1. By definition of \( x_{n+1} \) we have that \( \phi_n \geq 0 \). Let us write \( \phi_{n+1} - \phi_n = A + B \), where

\[
A = \int_C F(x, \bar{\eta}_{n+1}) \, d\bar{\eta}_{n+1}(x) - \int_C F(x, \bar{\eta}_n) \, d\bar{\eta}_n(x), \quad B = F(x_{n+1}, \bar{\eta}_n) - F(x_{n+1}, \bar{\eta}_{n+1}).
\]

We have

\[
B \leq F(x_{n+2}, \bar{\eta}_n) - F(x_{n+2}, \bar{\eta}_{n+1}) \leq F(x_{n+1}, \bar{\eta}_n) - F(x_{n+1}, \bar{\eta}_{n+1}) + C|x_{n+2} - x_{n+1}|d_1(\bar{\eta}_n, \bar{\eta}_{n+1}) \leq F(x_{n+1}, \bar{\eta}_n) - F(x_{n+1}, \bar{\eta}_{n+1}) + \frac{C}{n+1}|x_{n+2} - x_{n+1}|d_1(\delta_{x_{n+1}}, \bar{\eta}_n),
\]

where we have used (14) to pass from the first to the second inequality and (10) from the second to the third inequality. Similarly, using (11) and that \( F \) is Lipschitz,

\[
A = \int_C (F(x, \bar{\eta}_{n+1}) - F(x, \bar{\eta}_n)) \, d\bar{\eta}_n(x) + \frac{1}{n+1} \left[ F(x_{n+1}, \bar{\eta}_{n+1}) - \int_C F(x, \bar{\eta}_{n+1}) \, d\bar{\eta}_n(x) \right] \leq \int_C (F(x, \bar{\eta}_{n+1}) - F(x, \bar{\eta}_n)) \, d\bar{\eta}_n(x) + \frac{1}{n+1} \left[ F(x_{n+1}, \bar{\eta}_n) - \int_C F(x, \bar{\eta}_n) \, d\bar{\eta}_n(x) \right] + \frac{C}{n+1}d_1(\bar{\eta}_n, \bar{\eta}_{n+1}) \leq \int_C (F(x, \bar{\eta}_{n+1}) - F(x, \bar{\eta}_n)) \, d\bar{\eta}_n(x) - \frac{1}{n+1}\phi_n + \frac{C}{(n+1)^2}d_1(\bar{\eta}_n, \delta_{x_{n+1}}).
\]

On the other hand, the second relation in (11) yields \( -(n+1)(\bar{\eta}_{n+1} - \bar{\eta}_n) = \bar{\eta}_n - \delta_{x_{n+1}} \). Therefore,

\[
F(x_{n+1}, \bar{\eta}_n) - F(x_{n+1}, \bar{\eta}_{n+1}) + \int_C (F(x, \bar{\eta}_{n+1}) - F(x, \bar{\eta}_n)) \, d\bar{\eta}_n(x) = -(n+1) \int_C (F(x, \bar{\eta}_{n+1}) - F(x, \bar{\eta}_n)) \, d(\bar{\eta}_{n+1} - \bar{\eta}_n)(x) \leq 0,
\]

by the monotonicity condition of \( F \). From estimates (15)-(16) and inequality (17) we deduce that

\[
\phi_{n+1} - \phi_n \leq -\frac{1}{n+1}\phi_n + \frac{C}{n+1}d_1(\delta_{x_{n+1}}, \bar{\eta}_n) \left( \frac{1}{n+1} + |x_{n+2} - x_{n+1}| \right).
\]

Using that \( P(C) \) is compact (and so bounded in \( d_1 \)), we get that

\[
\phi_{n+1} - \phi_n \leq -\frac{1}{n+1}\phi_n + \frac{\epsilon_n}{n},
\]

where \( \epsilon_n := C' \left( \frac{1}{n+1} + |x_{n+2} - x_{n+1}| \right) \), with \( C' > 0 \) and independent of \( n \). Remark 3.1 implies that \( |x_{n+2} - x_{n+1}| \to 0 \) as \( n \to \infty \) (because \( d_1(\bar{\eta}_n, \bar{\eta}_{n+1}) = d_1(\bar{\eta}_n, \delta_{x_{n+1}})/(n+1) \to 0 \)). Thus, \( \epsilon_n \to 0 \) and the result follows from Lemma 3.1. \( \square \)

3.2 Convergence of the fictitious play for finite MFG

In this section, we apply the abstract result in Theorem 3.1 to the finite MFG problem \((\text{MFG}_d)\). Under the notations of Section 2, in what follows, will assume that \( c_{xy}(\cdot, \cdot) \) has a separable form. Namely,

\[
c_{xy}(p, M) = K(x, y, p) + f(x, M), \quad \forall \ x, \ y \in S, \ p, \ M \in P(S),
\]

where \( K : S \times S \times P(S) \to \mathbb{R} \) and \( f : S \times P(S) \to \mathbb{R} \) are given. In order to write \((\text{MFG}_d)\) as a particular instance of (12), given \( \eta \in P(K_S, \mathcal{T}) \) we define \( M_\eta := \mathcal{T} \to P(S) \) and \( F : K_S, \mathcal{T} \times P(K_S, \mathcal{T}) \to \mathbb{R} \) as

\[
M_\eta(k) := \int_{K_S, \mathcal{T}} M_{P_{\eta}}^M(k) \, d\eta(P), \quad \forall \ k = 0, \ldots, N, \quad \text{and} \quad F(P, \eta) := J_{M_\eta}(P).
\]
Under assumption (H1), we have that $F$ is continuous and satisfies the unique minimizer condition in Definition 3.2. Therefore, by Remark 3.1(i), associated to any equilibrium $\eta \in \mathcal{P}(K_{S,T})$ for $F$, i.e. $\eta$ satisfies (12) with $\mathcal{C} = K_{S,T}$, there exists $P_\eta \in K_{S,T}$ such that $\eta = \delta_{P_\eta}$, from which we get that $P_\eta$ solves (MFG$_d$). Conversely, for any solution $P$ to (MFG$_d$) we can associate the measure $\eta_P := \delta_P$, which solves (11). An analogous argument shows that the fictitious play procedures (9) and (11) are equivalent.

We consider now some assumptions on the data of the finite MFG problem that will ensure the validity of assumptions (i)-(ii) for $F$ in Theorem 3.1.

(H2) We assume that

(i) $f$ and $g$ are monotone, in the sense that setting $h = f, g$, we have

$$\sum_{x \in S} (h(x, M) - h(x, M')) (M(x) - M'(x)) \geq 0 \quad \forall \; M, \; M' \in \mathcal{P}(S).$$

(ii) $f$ and $g$ are Lipschitz with respect to their second argument.

The following result is a straightforward consequence of the definitions.

Lemma 3.2. If $f$ and $g$ are monotone, then $F$ is monotone in sense of Definition 3.1.

Proof. For any two distributions $\eta, \eta' \in \mathcal{P}(\mathcal{C})$ we want to show $\int_{\mathcal{C}} (F(P, \eta) - F(P, \eta')) \, d(\eta - \eta')(P) \geq 0$. By using the exact form of the cost function $F$ by equation (20) and taking into account the separable form of the running cost (19), we have:

$$F(P, \eta) - F(P, \eta') = \sum_{k=0}^{N-1} \sum_{x \in S} M^M_P(x, k) [f(x, M_\eta(k)) - f(x, M_{\eta'}(k))]$$

$$+ \sum_{x \in S} M^M_P(x, N) [g(x, M_\eta(N)) - g(x, M_{\eta'}(N))].$$

Thus,

$$\int_{K_{S,T}} (F(P, \eta) - F(P, \eta')) \, d(\eta - \eta')(P) = \sum_{k=0}^{N-1} \sum_{x \in S} [f(x, M_\eta(k)) - f(x, M_{\eta'}(k))] \int_{K_{S,T}} M^M_P(x, k) \, d(\eta - \eta')(P)$$

$$+ \sum_{x \in S} [g(x, M_\eta(N)) - g(x, M_{\eta'}(N))] \int_{K_{S,T}} M^M_P(x, N) \, d(\eta - \eta')(P)$$

$$= \sum_{k=0}^{N-1} \sum_{x \in S} [f(x, M_\eta(k)) - f(x, M_{\eta'}(k))] (M_\eta(x, k) - M_{\eta'}(x, k))$$

$$+ \sum_{x \in S} [g(x, M_\eta(N)) - g(x, M_{\eta'}(N))] (M_\eta(x, N) - M_{\eta'}(x, N)) \geq 0,$$

where the inequality above follows from from the monotonicity of $f$ and $g$. \qed

By Remark 3.1 we directly deduce the following result.

Proposition 3.1. If (H1) and (H2)(i) hold, then the finite MFG (MFG$_d$) has a unique equilibrium.

Remark 3.2. The previous result slightly improves [16, Theorem 6], where the uniqueness of the equilibrium is proved under a stronger strict monotonicity assumption on $f$ and $g$.

In order to check assumption (ii) in Theorem 3.1, we need first a preliminary result.

Lemma 3.3. There exists a constant $C > 0$ such that

$$|M^M_P(k) - M^M_{P'}(k)| \leq C|P - P'|_{\infty} \quad \forall \; P, \; P' \in K_{S,T}, \; k = 0, \ldots, N. \quad (21)$$

In particular,

$$|M_\eta(k) - M_{\eta'}(k)| \leq C|\eta - \eta'| \quad \forall \; \eta, \; \eta' \in \mathcal{P}(K_{S,T}), \; k = 0, \ldots, N. \quad (22)$$
Theorem 3.2. Assume that \( \eta \) holds. Then, there exists \( C > 0 \) such that

\[
|F(P, \eta) - F(P, \eta') - F(P', \eta) + F(P', \eta')| \leq C |P - P'|_{\infty} d_1(\eta, \eta'),
\]

\[
|F(P, \eta) - F(P, \eta')| \leq C d_1(\eta, \eta'),
\]  

for all \( P, P' \in \mathcal{K}_{S,T} \) and \( \eta, \eta' \in \mathcal{P}(\mathcal{K}_{S,T}) \).

Proof. Let us first prove the second relation in (24). By \((H2)\) and Lemma 3.3 we can write \( |F(P, \eta) - F(P, \eta')| \leq A + B \) with

\[
A := \sum_{k=0}^{N-1} \sum_{x \in S} M_P^{\mu_0}(x, k) |f(x, M_\eta(k)) - f(x, M_{\eta'}(k))| \leq c \sum_{k=0}^{N-1} \sum_{x \in S} M_P^{\mu_0}(x, k) d_1(\eta, \eta') = c N d_1(\eta, \eta'),
\]

and

\[
B := \sum_{x \in S} M_P^{\mu_0}(x, N) |g(x, M_\eta(N)) - g(x, M_{\eta'}(N))| \leq c \sum_{x \in S} M_P^{\mu_0}(x, N) d_1(\eta, \eta') = c d_1(\eta, \eta'),
\]

for some \( c > 0 \). Thus, the second estimate in (24) follows. In order to prove the first relation in (24), let us write \( |F(P, \eta) - F(P, \eta') - F(P', \eta) + F(P', \eta')| \leq A' + B' \) with

\[
A' := \sum_{k=0}^{N-1} \sum_{x \in S} |M_P(x, k) - M_{\eta'}(x, k)| |f(x, M_\eta(k)) - f(x, M_{\eta'}(k))| \leq C N |S| |P - P'|_{\infty} d_1(\eta, \eta'),
\]

\[
B' := \sum_{x \in S} |M_P(x, N) - M_{\eta'}(x, N)| |g(x, M_\eta(N)) - g(x, M_{\eta'}(N))| \leq C |S| |P - P'|_{\infty} d_1(\eta, \eta').
\]

The result follows. 

By combining Lemma 3.2, Lemma 3.4 and Theorem 3.1, we get the following convergence result.

Theorem 3.2. Assume \((H1)\) and \((H2)\) and let \( (P_n, M_n, \hat{M}_n) \) be the sequence generated in the fictitious play procedure (9). Then, \( (P_n, M_n, \hat{M}_n) \to (\hat{P}, M_\mu^{\mu_0}, M_\mu^{\mu_0}) \), where \( \hat{P} \) is the unique solution to (MFGd).
4 First order MFG as limits of finite MFG

In this section we consider a relaxed first order MFG problem in continuous time and with a continuum of states. We define a natural finite MFG associated to a discretization of the space and time variables. We address our second main question in this work, which is the convergence of the solutions of finite MFGs to solutions of continuous MFGs when the discretization parameters tend to zero.

In order to introduce the MFG problem, we need first to introduce some definitions. Let us define \( \Gamma := C([0,T];\mathbb{R}^d) \) and given \( m_0 \in \mathcal{P}(\mathbb{R}^d) \), called the initial distribution, let
\[
\mathcal{P}_{m_0}(\Gamma) = \{ \eta \in \mathcal{P}(\Gamma) : e_0 \mathcal{H}_0 \eta = m_0 \},
\]
where, for each \( t \in [0,T] \), the function \( e_t : \Gamma \to \mathbb{R}^d \) is defined by \( e_t(\gamma) = \gamma(t) \). Let \( \ell : \mathbb{R}^d \to \mathbb{R} \) and \( f, g : \mathbb{R}^d \times \mathcal{P}_1(\mathbb{R}^d) \to \mathbb{R} \). Given \( m \in C([0,T];\mathcal{P}_1(\mathbb{R}^d)) \) and \( q \in (1, +\infty) \), we consider the following family of variational problems, parametrized by the initial condition,
\[
\inf \left\{ \int_0^T [\ell(\dot{\gamma}(t)) + f(\gamma(t), m(t))] dt + g(\gamma(T), m(T)) \bigg| \gamma \in W^{1,q}([0,T]; \mathbb{R}^d), \gamma(0) = x \right\}, \quad x \in \mathbb{R}^d. \tag{25}
\]

**Definition 4.1.** We call \( \xi^* \in \mathcal{P}_{m_0}(\Gamma) \) a MFG equilibrium for (25) if \( [0,T] \ni t \mapsto e_t \xi^* \) belongs to \( C([0,T]; \mathcal{P}_1(\mathbb{R}^d)) \) and \( \xi^* \)-almost every \( \gamma \) solves the optimal control problem in (25) with \( x = \gamma(0) \) and \( m(t) = e_t \xi^* \) for all \( t \in [0,T] \).

Assuming that the cost functional of the optimal control problem in (25) is meaningful, which is ensured by the conditions on \( \ell \), \( f \) and \( g \) in assumption (H3) below, the interpretation of a MFG equilibrium is as follows: the measure \( \xi^* \) is an equilibrium if it only charges trajectories in \( \mathbb{R}^d \), distributed as \( m_0 \) at the initial time, minimizing a cost depending on the collection of time marginals of \( \xi^* \) in \( [0,T] \).

**Remark 4.1.** Usually, see e.g. [24] and [9], a first order MFG equilibrium is presented in the form of a system of PDEs consisting in a HJB equation, modelling the fact that a typical agent solves an optimal control problem, which depends on the marginal distributions of the agents at each time \( t \in [0,T] \), coupled with a continuity equation, describing the evolution of the aforementioned marginal distributions if the agents follow the optimal dynamics. The definition of equilibrium that we adopted in this work corresponds to a relaxation of the PDE notion of equilibrium, and has been used, for instance, in [12], [5, Section 3] and, recently, in [7].

Throughout this section, we will suppose that the following assumption holds.

(H3) (i) The function \( \ell \) is continuous and there exist constants \( \ell > 0 \), \( \ell > 0 \) and \( C_\ell > 0 \) such that
\[
\ell |\alpha|^q - C_\ell \leq \ell(\alpha) \leq \ell |\alpha|^q + C_\ell \quad \forall \alpha \in \mathbb{R}^d. \tag{26}
\]

(ii) For \( h = f \), \( g \) we have that \( h \) is continuous, \( h(\cdot, m) \) is \( C^1 \), for every \( m \in \mathcal{P}_1(\mathbb{R}^d) \), and there exists \( C > 0 \) such that
\[
\sup_{m \in \mathcal{P}_1(\mathbb{R}^d)} \{ ||h(\cdot, m)||_\infty + ||D_x h(\cdot, m)||_\infty \} \leq C. \tag{27}
\]

(iii) The initial distribution \( m_0 \in \mathcal{P}(\mathbb{R}^d) \) has a compact support.

Now we will focus on a particular class of finite MFGs and relate their solutions, asymptotically, with the MFG equilibria for (25). Let \( (N_n^s) \) and \( (N_n^d) \) be two sequences of natural numbers such that \( \lim_{n \to \infty} N_n^s = \lim_{n \to \infty} N_n^d = +\infty \) and let \( (\epsilon_n) \) be a sequence of positive real numbers such that \( \lim_{n \to \infty} \epsilon_n = 0 \). Define \( \Delta x_n := 1/N_n^s \) and \( \Delta t_n := T/N_n^d \). For a fixed \( n \in \mathbb{N} \), consider the discrete state set \( \mathcal{S}_n \) and the discrete time set \( \mathcal{T}_n \) defined as
\[
\mathcal{S}_n := \{ x_i := i \Delta x_n \mid i \in \mathbb{Z}^d, \ |i|_\infty \leq (N_n^s)^2 \} \subseteq \mathbb{R}^d,
\]
\[
\mathcal{T}_n := \{ t_k := k \Delta t_n \mid k = 0, \ldots, N_n^d \} \subseteq [0,T]. \tag{28}
\]
Let us also define the (non positive) entropy function $E_n: \mathcal{P}(S_n) \rightarrow \mathbb{R}$ by
\[
E_n(p) = \sum_{x \in S_n} p(x) \log(p(x)) \quad \forall p \in \mathcal{P}(S_n),
\]
with the convention that $0 \log 0 = 0$. For every $x \in S_n$, set $E^n_x := \{ x' \in \mathbb{R}^d \mid |x' - x| \leq \Delta x_n/2 \}$. Since we will be interested in the asymptotic as $n \to \infty$, we can assume, without loss of generality, that $m_0(\partial E^n_x) = 0$ for all $x \in S_n$. Similarly, by (H3)(iii), we can assume that the support of $m_0$ will be contained in $\cup_{x \in S_n} E^n_x$. Based on these considerations, setting
\[
M_{n,0}(x) := m_0(E^n_x) \quad \forall x \in S_n,
\]
we have that $M_{n,0} \in \mathcal{P}(S_n)$. We consider the finite MFG, written in a recursive form (see (4)),
\[
\begin{align*}
& (i) \quad U_n(x,t_k) = \min_{p \in \mathcal{P}(S_n)} \left\{ \sum_{y \in S_n} p(y) \left[ \Delta t_n \ell \left( \frac{y - x}{\Delta t_n} \right) + U_n(y,t_{k+1}) \right] + \epsilon_n E_n(p) \right\} \\
& \quad \quad \quad + \Delta t_n f(x,M_n(t_k)) \quad \forall x \in S_n, \ 0 \leq k < N^t_n, \\
& (ii) \quad M_n(y,t_{k+1}) = \sum_{x \in S_n} \hat{P}_n(x,y,t_k) M_n(x,t_k) \quad \forall y \in S_n, \ 0 \leq k < N^t_n, \\
& (iii) \quad M_n(x,0) = M_{n,0}(x), \quad U_n(x,T) = g(x,M_n(T)) \quad \forall x \in S_n,
\end{align*}
\] (29)
where for all $x \in S_n$, $0 \leq k \leq N^t_n - 1$, $\hat{P}_n (x,\cdot, t_k) \in \mathcal{P}(S_n)$ is given by
\[
\hat{P}_n(x,\cdot, t_k) = \arg\min_{p \in \mathcal{P}(S_n)} \left\{ \sum_{y \in S_n} p(y) \left[ \Delta t_n \ell \left( \frac{y - x}{\Delta t_n} \right) + U_n(y,t_{k+1}) \right] + \epsilon_n E_n(p) \right\},
\] (30)
and, by notational convenience, every $p \in \mathcal{P}(S_n)$ is identified with $\sum_{x \in S_n} p(x) \delta_x \in \mathcal{P}_1(\mathbb{R}^d)$. Note that system (29) is a particular case of (4), with
\[
c_{xy}(p,M) := \Delta t_n \left[ \ell \left( \frac{y - x}{\Delta t_n} \right) + f(x,M) \right] + \epsilon_n \log(p(y)).
\]

Remark 4.2. The positive parameter $\epsilon_n$ and the entropy term $E_n$ are introduced in (29) in order to ensure that $\hat{P}_n$ is well-defined, and so that assumption (H1) for system (29) is satisfied in this case. In particular, Remark 2.1 ensures the existence of at least one solution $(U_n, M_n)$ of (29), with associated transition kernel $\hat{P}_n$ given by (30).

In order to study the asymptotic behaviour of $(U_n, M_n, \hat{P}_n)$, let us first introduce some useful notations. We set $K_n := K_{S_n,T_n}$ (see Definition 2.1) and, given $x \in S_n$ and $t \in T_n$, we denote by $\Gamma_{x,t} \subseteq \Gamma_t$ the set of continuous functions $\gamma: [t, T] \rightarrow \mathbb{R}^d$ such that $\gamma(t) = x$ and, for each $1 \leq k \leq m$, with $t_k \in T_n \cap [t, T]$, we have that $\gamma(t_k) \in S_n$ and the restriction of $\gamma$ to the interval $[t_{k-1}, t_k]$ is affine. Given $P \in K_n$ let us define $\xi_{x,t}^{\gamma} \in \mathcal{P}(\Gamma_t)$ by
\[
\xi_{x,t}^{\gamma} := \sum_{\gamma \in \Gamma_{x,t} \cap \Gamma_t} p^{\gamma,x,t}_{\xi_{x,t}^{\gamma}}(\gamma) \delta_\gamma,
\]
where $p^{\gamma,x,t}_{\xi_{x,t}^{\gamma}}(\gamma) := \prod_{t_k \in T_n \cap [t,T]} P(\gamma(t_k), \gamma(t_{k+1}), t_k)$.
(31)

For a given Borel measurable function $L: \Gamma_t \rightarrow \mathbb{R}$ and $\xi \in \mathcal{P}(\Gamma_t)$ we will denote $E_\xi(L) := \int L(\gamma) d\xi(\gamma)$, provided that the integral is well-defined. Using these notations, expression (29)(i) is equivalent to
\[
U_n(x,t_k) = \min_{P \in K_n} \left\{ E_{\xi_{x,t}^{x,t,n}} \left( \Delta t_n \sum_{k' = k}^{N^t_n - 1} \left[ \ell \left( \frac{\gamma(t_{k'}) - \gamma(t_{k+1})}{\Delta t_n} \right) + f(\gamma(t_{k'}), M_n(t_{k'})) \right] \right) \right. \\
\left. + E_{\xi_{x,t}^{x,t,n}} \left( g(\gamma(T), M_n(T)) \right) + \epsilon_n E_{\xi_{x,t}^{x,t,n}} \left( \sum_{k' = k}^{N^t_n - 1} \log P(\gamma(t_{k'}), \gamma(t_{k'+1}), t_{k'})) \right) \right\},
\] (32)
for all \( x \in \mathcal{S}_n \) and \( k = 0, \ldots, N_n' - 1 \). For latter use, note that since the support of \( \xi_{p}^{x,t_k,n} \) is contained in \( \Gamma_{x,t_k} \), for \( \xi_{p}^{x,t_k,n} \) almost every \( \gamma \in \Gamma_t \) we have that \( \gamma(t) = (\gamma(t_{k' + 1}) - \gamma(t_{k'}))/\Delta t_n \) for every \( k' = k, \ldots, N_n' - 1 \) and \( t \in (t_{k'}, t_{k' + 1}) \), and, hence,

\[
\mathbb{E}_{\xi_{p}^{x,t_k,n}} \left( \Delta t_n \ell \left( \frac{\gamma(t_{k' + 1}) - \gamma(t_{k'})}{\Delta t_n} \right) \right) = \mathbb{E}_{\xi_{p}^{x,t_k,n}} \left( \int_{t_{k'}}^{t_{k' + 1}} \ell \left( \gamma(t) \right) dt \right). \tag{33}
\]

Finally, let us define \( \xi_n \in \mathcal{P}(\Gamma) \) by

\[
\xi_n := \sum_{x \in \mathcal{S}} M_n(0|x) \xi_{p}^{x,0,n}. \tag{34}
\]

Notice that, by definition, \( M_n(t) = e_t \xi_n \) for all \( t \in \mathcal{I}_n \). We extend \( M_n : \mathcal{I}_n \rightarrow \mathcal{P}_1(\mathbb{R}^d) \) to \( M_n : [0,T] \rightarrow \mathcal{P}_1(\mathbb{R}^d) \) via the formula

\[
M_n(t) := e_t \xi_n \quad \text{for all } t \in [0,T]. \tag{35}
\]

### 4.1 Convergence analysis

We now study the limit behaviour of the solutions \((U_n, M_n)\) in (29), and of the associated sequence \((\xi_n)\), as \( n \to \infty \). We will need the following preliminary result.

**Lemma 4.1.** Suppose that \( \epsilon_n = O \left( \frac{1}{N_n \log(N_n')} \right) \). Then, there exists \( C > 0 \), independent of \( n \), such that

\[
\sup_{x \in \mathcal{S}_n, t \in \mathcal{I}_n} |U_n(x,t)| \leq C, \tag{36}
\]

\[
\mathbb{E}_{\xi_n} \left( \int_0^T |\gamma(t)|^q dt \right) \leq C. \tag{37}
\]

**Proof.** Let us first prove (36). Since the cardinality of \( \mathcal{S}_n \) is equal to \((2(N_n')^2+1)^d\), we have that

\[
\left( \frac{1}{(2(N_n')^2+1)^d}, \ldots, \frac{1}{(2(N_n')^2+1)^d} \right) \text{ argmin} \left\{ \sum_{x \in \mathcal{S}_n} p_x \log p_x : p \in \mathcal{P}(\mathcal{S}_n) \right\}.
\]

Hence, our assumption over \( \epsilon_n \) implies the existence of \( \tilde{C} > 0 \), independent of \( n \), such that for all \( x \in \mathbb{R}^d \), \( t = t_k \) \((k = 0, \ldots, N_n' - 1)\), we have

\[
\left| \epsilon_n \mathbb{E}_{\xi_{p}^{x,t_k,n}} \left( \sum_{k'=k}^{N_n'-1} \sum_{y \in \mathcal{S}_n} \mathcal{P}(\gamma(t_{k'}), y, t_{k'}) \log \mathcal{P}(\gamma(t_{k'}), y, t_{k'}) \right) \right| \leq \tilde{C} \quad \forall \mathcal{P} \in \mathcal{K}_n. \tag{38}
\]

Thus, the lower bound is a direct consequence of the lower bounds for \( \ell \) in (26) and for \( f \) and \( g \) in (27). In order to obtain the upper bound, choose \( \mathcal{P} \in \mathcal{K}_n \) in the right hand side of (32) such that \( \mathcal{P}(x,x,t_{k'}) = 1 \) for all \( k' = k, \ldots, N_n' - 1 \). The bounds in (26)-(27) imply that

\[
U_n(x,t_k) \leq (C + C \ell) (T + 1),
\]

and so (36) follows. Finally, by the lower bound in (26), the definition of \( \xi_n \), expression (32), estimate (36), with \( t = 0 \), and (27) we have the existence of \( C > 0 \), independent of \( n \), such that

\[
\mathbb{E}_{\xi_n} \left( \int_0^T |\gamma(t)|^q dt \right) = \mathbb{E}_{\xi_n} \left( \Delta t_n \sum_{k=0}^{N_n'-1} \left| \frac{\gamma(t_{k+1}) - \gamma(t_k)}{\Delta t_n} \right|^q \right) \leq \mathbb{E}_{\xi_n} \left( \frac{\Delta t_n}{2} \sum_{k=0}^{N_n'-1} \ell \left( \frac{\gamma(t_{k+1}) - \gamma(t_k)}{\Delta t_n} \right) + C(T) \right) \leq C. \tag{39}
\]
In the proof of the next result, and in the remainder of this article, we set $q' := q/(q - 1)$.

**Lemma 4.2.** Let $C > 0$. Then the set
\[
\Gamma_C := \left\{ \gamma \in W^{1,q}([0, T]; \mathbb{R}^d) \mid |\gamma(0)| \leq C \text{ and } \int_0^T |\dot{\gamma}(t)|^q dt \leq C \right\},
\]
is a compact subset of $\Gamma$.

**Proof.** Let $(\gamma_n)$ be a sequence in $\Gamma_C$. Then, for all $0 \leq s \leq t \leq T$, Hölder’s inequality yields
\[
|\gamma_n(t) - \gamma_n(s)| \leq \int_s^t |\dot{\gamma}_n(t')|dt' \leq C^{1/q}(t-s)^{1/q'}.
\]
Thus,
\[
|\gamma_n(t)| \leq |\gamma_n(0)| + |\gamma_n(t) - \gamma_n(0)| \leq C + C^{1/q}T^{1/q'}.
\]
As a consequence of (40)-(41) and the Arzelà-Ascoli theorem we have existence of $\gamma \in \Gamma$ such that, up to some subsequence, $\gamma_n \to \gamma$ uniformly in $[0, T]$. Moreover, since $\dot{\gamma}_n$ is bounded in $L^q((0, T); \mathbb{R}^d)$ and the function $L^q((0, T); \mathbb{R}^d) \ni z \mapsto \int_0^T |z(t)|^q dt \in \mathbb{R}$ is convex and continuous, and hence, weakly lower semicontinuous, we have the existence of $\bar{z} \in L^q((0, T); \mathbb{R}^d)$ such that, up to some subsequence, $\dot{\gamma}_n \rightharpoonup \bar{z}$ weakly in $L^q((0, T); \mathbb{R}^d)$ and $\int_0^T |\dot{\gamma}_n(t)|^q dt \leq \liminf_{n \to \infty} \int_0^T |\dot{\gamma}_n(t)|^q dt \leq C$. By passing to the limit in the equality
\[
\gamma_n(t) = \gamma_n(0) + \int_0^t \dot{\gamma}_n(s) ds \quad \forall \ t \in [0, T],
\]
we get that
\[
\gamma(t) = \gamma(0) + \int_0^t \bar{z}(s) ds \quad \forall \ t \in [0, T],
\]
and, hence, $\gamma \in W^{1,q}((0, T); \mathbb{R}^d)$, with $\dot{\gamma} = \bar{z}$ a.e. in $[0, T]$, $|\gamma(0)| \leq C$ and $\int_0^T |\dot{\gamma}(t)|^q dt \leq C$. Therefore, $\gamma \in \Gamma_C$ and, hence, the set $\Gamma_C$ is compact.

As a consequence of the previous results we easily obtain a compactness property for the sequence $(\xi_n)$.

**Proposition 4.1.** Suppose that $\epsilon_n = O\left(\frac{1}{\log(N_n)}\right)$. Then, the sequence $(\xi_n)$ is a relatively compact subset of $P(\Gamma)$ endowed with the topology of narrow convergence.

**Proof.** By Prokhorov’s theorem it suffices to show that $(\xi_n)$ is tight, i.e. we need to prove that for every $\varepsilon > 0$ there exists a compact set $K_{\varepsilon} \subseteq \Gamma$ such that $\sup_{n \in \mathbb{N}} \xi_n(\Gamma \setminus K_{\varepsilon}) \leq \varepsilon$. Given $\varepsilon > 0$, the bound (39) and the Markov’s inequality yield
\[
\xi_n\left(\left\{ \gamma \in \Gamma \mid \gamma \in W^{1,q}((0, T); \mathbb{R}^d) \text{ and } \int_0^T |\dot{\gamma}(t)|^q dt > \frac{C}{\varepsilon} \right\}\right) \leq \varepsilon \quad \forall \ n \in \mathbb{N}.
\]
On the other hand, by (H3)(iii), there exists $c_0 > 0$ such that for $\xi_n$-almost every $\gamma \in \Gamma$ we have $|\gamma(0)| \leq c_0$. By Lemma 4.2 and (42), the set $K_{\varepsilon} := \Gamma_{C_{\varepsilon}}$ with $C_{\varepsilon} := \max\{c_0, C/\varepsilon\}$, satisfies the required properties.

Now, we study the compactness of the collection of marginal laws, with respect to the time variables, in the space $C([0, T]; P_1(\mathbb{R}^d))$.

**Proposition 4.2.** Suppose that $\epsilon_n = O\left(\frac{1}{\log(N_n)}\right)$. Then, there exists $C > 0$ such that
\[
\int_{\mathbb{R}^d} |x|^q dM_n(t)(x) = \mathbb{E}_{\xi_n}(\vert\gamma(t)\vert^q) \leq C \quad \forall \ t \in [0, T],
\]
\[
d_1(M_n(t), M_n(s)) \leq C|t - s|^{1/q'} \quad \forall \ t, s \in [0, T],
\]
for all $n \in \mathbb{N}$. As a consequence, $M_n \in C([0, T]; P_1(\mathbb{R}^d))$ for all $n \in \mathbb{N}$ and the sequence $(M_n)$ is a relatively compact subset of $C([0, T], P_1(\mathbb{R}^d))$. 

13
Remark 4.3. Standard arguments using (48) show that $u$ sense, to a viscosity solution of $H$

now examine the limit behaviour of the corresponding optimal discrete costs ($\xi^*$). In [3, Proposition 1.3 and Remark 1.1] the existence of a viscosity solution

Classical results imply that under $\xi^*$ converging to $\xi^*$ exists at least one) and, for notational convenience, we still label by $\nu$ for some constant $C > 0$, independent of $n$. In the second inequality above we have used that $m_0$ has compact support and (39). This proves (43). In order to prove (44), by definition of $d_1$, we have that $d_1(M_n(t), M_n(s)) \leq d_q(M_n(t), M_n(s))$ and, setting $\rho_n := (\epsilon_1, \epsilon_2)\xi_n \in \mathcal{P}(\mathbb{R}^d \times \mathbb{R}^d)$,

$$
d_q^2(M_n(t), M_n(s)) \leq \int_{\mathbb{R}^d \times \mathbb{R}^d} |x - y|^d \rho_n(x, y) = \int_{\Gamma} |\gamma(t) - \gamma(s)|^q \, d\xi_n(\gamma)
$$

$$
\leq |t - s|^q \int_0^T |\dot{\gamma}(t)|^q \, d\xi_n(\gamma) = |t - s|^q \mathbb{E}_{\xi_n} \left( \int_0^T |\dot{\gamma}(t)|^q \, dt \right) \leq C |t - s|^q',
$$

from which (44) follows.

Finally, relation (43) implies that for all $t \in [0, T]$ the set $\{M_n(t) : n \in \mathbb{N}\}$ is relatively compact in $\mathcal{P}_1(\mathbb{R}^d)$ (see [1, Proposition 7.1.5]) and (44) implies that the family $(M_n)$ is equicontinuous in $C([0, T]; \mathcal{P}_1(\mathbb{R}^d))$. Therefore, the last assertion in the statement of the proposition follows from the Arzelà-Ascoli theorem.

Suppose that $\epsilon_n = O(1 / (N_n^q \log(N_n^q)))$ and let $\xi^* \in \mathcal{P}(\Gamma)$ be a limit point of $(\xi_n)$ (by Proposition 4.1 there exists at least one) and, for notational convenience, we still label by $n \in \mathbb{N}$ a subsequence of $(\xi_n)$ narrowly converging to $\xi^*$. By Proposition 4.2, we have that $(M_n)$ converges to $m(\cdot) := \epsilon_n \xi^* \in C([0, T]; \mathcal{P}_1(\mathbb{R}^d))$. We now examine the limit behaviour of the corresponding optimal discrete costs $(U_n)$. Defining the Hamiltonian $H : \mathbb{R}^d \to \mathbb{R}$ by

$$H(z) := \sup_{z^* \in \mathbb{R}^d} \{-z \cdot z^* - \ell(z^*)\} \quad \forall \ z \in \mathbb{R}^d,
$$

and assuming that $\epsilon_n = o(1 / (N_n^q \log(N_n^q)))$, in Proposition 4.3 we prove that $(U_n)$ converges, in a suitable sense, to a viscosity solution of

$$
-\partial_t u + H(\nabla u) = f(x, m(t)) \quad x \in \mathbb{R}^d, \ t \in (0, T),
$$

$$u(x, T) = g(x, m(T)) \quad x \in \mathbb{R}^d.
$$

Classical results imply that under (H3)(i)-(ii) equation (47) admits at most one viscosity solution (see e.g. [14, Theorem 2.1]). In [3, Proposition 1.3 and Remark 1.1] the existence of a viscosity solution $u$ is proved, as well the following representation formula: for all $(x, t) \in \mathbb{R}^d \times (0, T)$

$$u(x, t) = \inf_{\gamma \in W^{1,q}[0, T] ; \gamma(t) = x} \left\{ \int_0^T [\ell(\dot{\gamma}(s)) + f(\gamma(s), m(s))] \, ds + g(\gamma(T), m(T)) \right\}.
$$

(48)

Standard arguments using (48) show that $u$ is continuous in $\mathbb{R}^d \times [0, T]$ (see e.g. [3, Theorem 2.1]).

Remark 4.3. Definition 4.1 can thus be rephrased as follows: $\xi^* \in \mathcal{P}_{m_0}(\Gamma)$ is a MFG equilibrium for (25) if $[0, T] \ni t \mapsto m(t) := \epsilon_1 \xi^*$ belongs to $C([0, T]; \mathcal{P}_1(\mathbb{R}^d))$ and for $\xi^*$-almost all $\gamma$ we have that

$$u(\gamma(0), 0) = \int_0^T [\ell(\dot{\gamma}(t)) + f(\gamma(t), m(t))] \, dt + g(\gamma(T), m(T)),
$$

where $u$ is the unique viscosity solution to (47).

In order to prove the convergence of $U_n$ to $u$, we will need the following auxiliary functions

$$U^*(x, t) := \limsup_{\gamma_n \rightharpoonup_x} U_n(y, s) \quad U_*(x, t) := \liminf_{\gamma_n \rightharpoonup_x} U_n(y, s) \quad \forall \ x \in \mathbb{R}^d, \ t \in [0, T].
$$

(50)
By Lemma 4.1, the functions $U^*$ and $U_*$ are well defined if $\epsilon_n = O\left(1/(N_n^t \log(N_n^o))\right)$. In some of the next results, we will need to assume a stronger hypothesis on $\epsilon_n$, namely $\epsilon_n = o\left(1/(N_n^t \log(N_n^o))\right)$, which will allow us to eliminate the entropy term in the limit.

Before proving the convergence of the value functions, we will need a preliminary result.

**Lemma 4.3.** Assume that $\epsilon_n = O\left(1/(N_n^t \log(N_n^o))\right)$. Then,

(i) $U^*$ and $U_*$ are upper and lower semicontinuous, respectively.

(ii) If in addition, $\epsilon_n = o\left(1/(N_n^t \log(N_n^o))\right)$, we have that $U^*(x,T) = U_*(x,T) = g(x,m(T))$ for all $x \in \mathbb{R}^d$.

**Proof.** The proof of assertion (i) is the same than the proof of [2, Chapter V, Lemma 1.5]. Let us prove (ii). For $n \in \mathbb{N}$, let $x^n \in S_n$, $t^n \in T_n$ and $k : \mathbb{N} \to \mathbb{N}$ such that $t^n = t_{k(n)}$ (recall that $T_n = \{0,t_1,\ldots,t_{N_n^t}\}$). Because of our assumption on $\epsilon_n$, we can write

$$U_n(x^n, t^n) = \sum_{\gamma \in \Gamma_{x^n,t^n}} p_{\gamma} \left(\gamma\right) \left(\sum_{k=k(n)}^{N_n^t-1} \Delta t_n \left[f\left(\frac{\gamma(t_{k+1}) - \gamma(t_k)}{\Delta t_n}\right) + g\left(\gamma(t_k), M_n(t_k)\right)\right] + g\left(\gamma(T), M_n(T)\right)\right) + o(1),$$

where we recall that $p_{\gamma}$ is defined in (31). Using the definition of $U_n$ and arguing as in the proof of Lemma 4.1, we have that

$$\sum_{k=k(n)}^{N_n^t-1} \Delta t_n f\left(\gamma(t_k), M_n(t_k)\right) = O(T - t^n),$$

$$U_n(x^n, t^n) \leq g(x^n, M_n(T)) + O(T - t^n) + o(1).$$

Therefore, if $x^n \to x \in \mathbb{R}^d$ and $t^n \to T$, we have

$$\lim_{n \to \infty} \sup U_n(x^n, t^n) \leq g(x, M(T)),$$

from which we deduce that $U^*(x,T) \leq g(x, M(T))$ for all $x \in \mathbb{R}^d$. Next, for every $\gamma \in \Gamma_{x^n,t^n}$ we have

$$|\gamma(T) - x_n|^q \leq \left(\sum_{k=k(n)}^{N_n^t-1} |\gamma(t_{k+1}) - \gamma(t_{k+1})|^q\right)^{\frac{1}{q}} \leq (N_n^t - k(n))^{q-1} \sum_{k=k(n)}^{N_n^t-1} |\gamma(t_{k+1}) - \gamma(t_{k+1})|^q,$$

which implies that

$$\sum_{k=k(n)}^{N_n^t-1} \Delta t_n \left|\frac{\gamma(t_{k+1}) - \gamma(t_k)}{\Delta t_n}\right|^q \geq \frac{\Delta t_n}{(N_n^t - k(n))^{q-1}} \left|\gamma(T) - x_n\right|^q = \frac{1}{(T - t^n)^{q-1}} \left|\gamma(T) - x_n\right|^q.$$

Thus, setting $p_{\gamma}^{x^n,t^n} := \delta_{\gamma}^{x^n,t^n} (\{\gamma \in \Gamma_{t^n} | \gamma(T) = y\})$, the bounds (26), (27), (52) and equation (51) yield

$$U_n(x^n, t^n) \geq \min_{y \in S_n} \left\{\frac{\ell |y - x^n|^q}{(T - t^n)^{q-1}} + g(y, M_n(T))\right\} + O(T - t^n) + o(1),$$

Suppose that $y^n_*$ minimizes the “min” term in the last line above. By definition, we have

$$\frac{\ell |y^n_* - x^n|^q}{(T - t^n)^{q-1}} \leq g(x^n, M_n(T)) - g(y^n_*, M_n(T)) \leq C |y^n_* - x^n|,$$
where the last inequality follows from (27). As a consequence, we get that \( |y_n^* - x^n| = O(T - t^n) \) and so \( \frac{|y_n^* - x^n|}{(T - t^n)^{\gamma - 1}} \to 0 \) as \( n \to \infty \). Therefore, as \( n \to \infty \),

\[
\min_{y \in S_n} \left\{ \frac{\|y - x^n\|}{(T - t^n)^{\gamma - 1}} + g(y, M_n(T)) \right\} = \frac{\|y_n^* - x^n\|}{(T - t^n)^{\gamma - 1}} + g(y_n^*, M_n(T)) \to g(x(m(T))).
\]

By (53), this implies that

\[
\liminf_{n \to \infty} U_n(x^n, t^n) \geq g(x(m(T)),
\]

from which we deduce that \( U^*(x, T) \geq g(x(m(T))) \). The result follows.

Now, we prove the convergence of the sequence \( (U_n) \). The argument of the proof uses some ideas from the theory of approximation of viscosity solutions (see e.g. [4]).

**Proposition 4.3.** Assume that, as \( n \to \infty \), \( N_k^n / N_s^n \to 0 \) and \( \epsilon_n = o \left( \frac{1}{N_k^n \log(N_k^n)} \right) \). Then, \( U^* = U_* = u \), where \( u \) is given by (48), or equivalently, where \( u \) is the unique continuous viscosity solution to (47). As a consequence, for every compact set \( Q \subseteq \mathbb{R}^d \) we have that

\[
\sup_{(x,t) \in (S_n \cap Q) \times T_n} |U_n(x,t) - u(x,t)| \to 0 \quad \text{as} \quad n \to \infty.
\]

**Proof.** Let us prove that \( U^* \) is a viscosity subsolution of equation (47). Let \( \phi \in C^1(\mathbb{R}^d \times [0,T]) \) and \( (x^*,t^*) \in \mathbb{R}^d \times (0,T) \) be such that \( (x^*,t^*) \) is a local maximum of \( U^* - \phi \) on \( \mathbb{R}^d \times (0,T) \).

By standard arguments in the theory of viscosity solutions (see e.g. [2, Chapter II]), we may assume that \( \phi \) is bounded as well as its time and space derivatives and that \( (x^*,t^*) \) is a strict global maximum of \( U^* - \phi \). Arguing as in the proof of [2, Chapter V, Lemma 1.6], we can show the existence of a sequence \( (x^n,t^n) \) in \( S_n \times T_n \) such that \( (x^n,t^n) \to (x^*,t^*) \), \( U_n(x^n,t^n) \to U^*(x^*,t^*) \) and \( U_n - \phi \) has maximum at \( (x^n,t^n) \) in the set \( (S_n \times T_n) \cap B_{\delta} \), where \( B_{\delta} := \{(x,t) \in \mathbb{R}^d \times (0,T) : |x-x^*| + |t-t^*| \leq \delta \} \) and \( \delta > 0 \) is such that \( B_{\delta} \subseteq \mathbb{R}^d \times (0,T) \).

Now, let \( \xi \in C^\infty(\mathbb{R}^d \times [0,T]) \) be such that \( 0 \leq \xi \leq 1 \), \( \xi(x,t) = 0 \) if \( (x,t) \in B_{\frac{\delta}{2}} \) and \( \xi(x,t) = 1 \) if \( (x,t) \in (\mathbb{R}^d \times (0,T)) \setminus B_{\delta} \). Then, using that \( U_n \) and \( \phi \) are bounded, we can choose \( M > 0 \) large enough such that, setting \( \tilde{\phi} := \phi + M \xi \), the function \( U_n - \tilde{\phi} \) has maximum in \( S_n \times T_n \) at the point \( (x^n,t^n) \). Note that \( \partial_t \tilde{\phi}(x^*,t^*) = \partial_t \phi(x^*,t^*) \) and \( \nabla \tilde{\phi}(x^*,t^*) = \nabla \phi(x^*,t^*) \).

As in the proof of Lemma 4.3, let \( k : \mathbb{N} \to \mathbb{N} \) be such that \( t^n = t_{k(n)} \). Since \( U_n(x^n,t^n) \) satisfies

\[
U_n(x^n, t^n) = \min_{p \in P(S_n)} \sum_{y \in S_n} p(y) \left( \Delta t_n \ell \left( \frac{y - x^n}{\Delta t_n} \right) + \Delta t_n f(x^n, M_n(t^n)) + U_n(y, t_{k(n)+1}) \right) + \epsilon_n E_n(p),
\]

and \( U_n(y, t_{k(n)+1}) - U_n(x^n, t^n) \leq \tilde{\phi}(y, t_{k(n)+1}) - \tilde{\phi}(x^n, t^n) \) for all \( y \in S_n \), we have that

\[
0 \leq \min_{p \in P(S_n)} \sum_{y \in S_n} p(y) \left( \Delta t_n \ell \left( \frac{y - x^n}{\Delta t_n} \right) + \Delta t_n f(x^n, M_n(t_{k(n)})) + \tilde{\phi}(y, t_{k(n)+1}) - \tilde{\phi}(x^n, t_{k(n)}) \right) + \epsilon_n E_n(p),
\]

\[
\leq \min_{y \in S_n} \left\{ \Delta t_n \ell \left( \frac{y - x^n}{\Delta t_n} \right) + \Delta t_n f(x^n, M_n(t_{k(n)})) + \tilde{\phi}(y, t_{k(n)+1}) - \tilde{\phi}(x^n, t_{k(n)}) \right\} + \epsilon_n E_n(p),
\]

(55)

where the second inequality follows from the first one by taking for each \( y \in S_n \) the vector \( p \in P(S_n) \) defined as \( p(z) = 1 \) iff \( z = y \). Dividing by \( \Delta t_n \) and recalling that \( \epsilon_n = o \left( \frac{1}{N_k^n \log(N_k^n)} \right) \), we get

\[
0 \leq f(x^n, M_n(t^n)) + \min_{y \in S_n} \left\{ \ell \left( \frac{y - x^n}{\Delta t_n} \right) + \frac{\tilde{\phi}(y, t_{k(n)+1}) - \tilde{\phi}(x^n, t_{k(n)})}{\Delta t_n} \right\} + o(1),
\]

16
and so, taking liminf,
\[
0 \leq f(x^*, m(t^*)) + \liminf_{n \to \infty} \min_{y \in S_n} \left\{ \ell \left( \frac{y - x^n}{\Delta t_n} \right) + \frac{\partial \phi(y, t_{k(n)}+1) - \phi(x^n, t_{k(n)})}{\Delta t_n} \right\},
\]
where we have used that \( M_n \to m \) in \( C([0, T]; P_1(\mathbb{R}^d)) \). Let us study the second term in the right hand side above. For fixed \( n \), let \( y^*_n \) be such that
\[
y^*_n \in \arg\min_{y \in S_n} \left\{ \ell \left( \frac{y - x^n}{\Delta t_n} \right) + \frac{\partial \phi(y, t_{k(n)}+1) - \phi(x^n, t_{k(n)})}{\Delta t_n} \right\},
\]
or equivalently, setting \( \alpha^*_n := \frac{y^*_n - x^n}{\Delta t_n} \),
\[
\ell (\alpha^*_n) + \frac{\partial \phi(x^n + \Delta t_n \alpha^*_n, t_{k(n)}+1) - \phi(x^n, t_{k(n)})}{\Delta t_n} \leq \ell \left( \frac{y - x^n}{\Delta t_n} \right) + \frac{\partial \phi(y, t_{k(n)}+1) - \phi(x^n, t_{k(n)})}{\Delta t_n},
\]
for all \( y \in S_n \). By taking \( y = x^n \) in the expression above, using that \( \partial_t \vec{\phi} \) and \( \nabla \vec{\phi} \) are bounded and the growth condition (26) on \( \ell \), we obtain that the sequence \( (\alpha^*_n) \) is bounded. Let \( \alpha^* \) be a cluster point of this sequence and consider a subsequence of \( (\alpha_n) \), still indexed by \( n \), such that \( \alpha^*_n \to \alpha^* \). The condition \( N_n/\bar{N}_n \to 0 \) implies that for any \( \alpha \in \mathbb{R}^d \) we can find a sequence \( (y^n) \) in \( S_n \) such that \( \frac{x^n - \bar{x}^n}{\Delta t_n} \to \alpha \) as \( n \to \infty \). Taking \( y = y^n \) in (57) and passing to the limit yields
\[
\ell (\alpha^*) + \nabla \phi(x^*, t^*) \cdot \alpha^* \leq \ell (\alpha) + \nabla \phi(x^*, t^*) \cdot \alpha \quad \forall \alpha \in \mathbb{R}^d,
\]
which implies, by the definition of \( H \) in (46), that
\[
-\ell (\alpha^*) - \nabla \phi(x^*, t^*) \cdot \alpha^* = H(\nabla \phi(x^*, t^*)).
\]
Since the previous equality holds for any cluster point of \( \alpha_n \), we deduce that
\[
\liminf_{n \to \infty} \min_{y \in S_n} \left\{ \ell \left( \frac{y - x^n}{\Delta t_n} \right) + \frac{\partial \phi(y, t_{k(n)}+1) - \phi(x^n, t_{k(n)})}{\Delta t_n} \right\} = -H(\nabla \phi(x^*, t^*)) + \partial_t \phi(x^*, t^*),
\]
and, hence, (56) gives
\[
-\partial_t \phi(x^*, t^*) + H(\nabla \phi(x^*, t^*)) \leq f(x^*, m(t^*)),
\]
which proves that \( U^* \) is a subsolution to (47). An analogous argument shows that \( U_* \) is a supersolution to (47). Assumptions (H3)(i)-(ii) ensure a comparison principle for (47) (see [14, Theorem 2.1]). Therefore, since \( U^*(\cdot, T) = U_* (\cdot, T) \) by Lemma 4.3(ii), we have that \( U^* = U_* = u \) as announced. Using this result, the proof of (54) is identical to the proof of [2, Chapter V, Lemma 1.9]. □

We have now all the elements to prove the main result in this article. We will need an additional assumption over \( \ell, f \) and \( g \).

(H4) We assume that:
(i) The function \( \ell \) is convex.
(ii) There exists \( C > 0 \) and a modulus of continuity \( \omega : [0, +\infty) \to [0, +\infty) \) such that for \( h = f, g \) we have
\[
|h(x, m) - h(x, m')| \leq C(1 + |x|^q) \omega (d_1(m, m')) \quad \forall x \in \mathbb{R}^d, m, m' \in \mathcal{P}_1(\mathbb{R}^d).
\]

**Theorem 4.1.** Suppose that (H3)-(H4) hold and that, as \( n \to \infty \), \( N^+_n/N^-_n \to 0 \) and \( \epsilon_n = o \left( \frac{1}{N_{t_n} \log(N_{t_n})} \right) \). Then, the following assertions hold true:

(i) There exists at least one limit point \( \xi^* \) of \( (\xi_n) \), with respect to the narrow topology in \( \mathcal{P}(\Gamma) \), and every such limit point is an MFG equilibrium for (25).
(ii) Consider any converging subsequence of \( (\xi_{n'}) \) of \( (\xi_n) \), with limit \( \xi^* \in \mathcal{P}(\Gamma) \), and let \( (U_{n'}, M_{n'}) \) be the associated solutions to (29). Denote by \( u \) be the unique viscosity solution to (47) with \( m(t) := e_{t^*} \xi^* \) for all \( t \in [0, T] \). Then, the sequence \( (M_{n'}) \subseteq C([0, T]; \mathcal{P}_1(\mathbb{R}^d)) \), defined by (35), converge to \( m \) in \( C([0, T]; \mathcal{P}_1(\mathbb{R}^d)) \) and (54) holds for \( (U_{n'}) \) and \( u \).
Proof. Assertion (ii) is a straightforward consequence of the first assertion and Proposition 4.3, hence, we only need to prove (i). The existence of at least one limit point \( \xi^* \) of \((\xi_n)\) is a consequence of Proposition 4.1. Let us still index by \( n \) a subsequence of \((\xi_n)\) narrowly converging to \( \xi^* \). By Proposition 4.2, we have that \( m(\cdot) := e(\cdot)\xi^* \) is the limit in \( C([0, T]; P_1(\mathbb{R}^d)) \) of \( M_n \). By definition of \( \xi_n \) and our condition over \( \epsilon_n \), we have

\[
\mathbb{E}_{\xi_n} \left( \int_0^T [\ell(\gamma(t)) + f(\gamma(t), t, M_n([t]_{\tau_n}))] \, dt + g(\gamma(T), M_n(T)) \right) + o(1) = \sum_{x \in S_n} U_n(x, 0) M_{n, 0}(x),
\]

where \([t]_{\tau_n} \) is the greatest element in \( \tau_n \) not larger than \( t \). Using that the support of \( M_{n, 0} \) is uniformly bounded and relation (54) in Proposition 4.3, we easily get that the right hand side above converges to

\[
\int_{\mathbb{R}^d} u(x, 0) dm_0(x) = \mathbb{E}_{\xi^*}(u(\gamma(0), 0)),
\]

where \( u \) is the unique viscosity solution to (47). On the other hand, arguing as in the proof of Lemma 4.2, the lower bound in (26) and the convexity of \( \ell \) imply that the mapping

\[
\Gamma \ni \gamma \mapsto \int_0^T \ell(\gamma) \, dt, \quad \text{if } \gamma \in W^{1, q}([0, T]; \mathbb{R}^d),
\]

is lower semicontinuous. Therefore, by [1, Lemma 5.1.7] and (37), we have

\[
\mathbb{E}_{\xi^*} \left( \int_0^T \ell(\gamma(t)) \, dt \right) \leq \liminf_{n \to \infty} \mathbb{E}_{\xi_n} \left( \int_0^T \ell(\gamma(t)) \, dt \right) < \infty,
\]

which, together with the lower bound in (26), implies that the support of \( \xi^* \) is contained in \( W^{1, q}([0, T]; \mathbb{R}^d) \).

By assumption \((H3)\)(ii), for all \( k = 0, \ldots, n^d - 1 \) we have that

\[
\left| \mathbb{E}_{\xi_n} \left( \int_{t_k}^{t_{k+1}} [f(\gamma(t), M_n(t)) - f(\gamma(t), M_n(t_k))] \, dt \right) \right| \leq C \mathbb{E}_{\xi_n} \left( \int_{t_k}^{t_{k+1}} |\gamma(t) - \gamma(t_k)| \, dt \right).
\]

Since \( \gamma(t) = \gamma(t_k) + \dot{\gamma}(t_k)(t - t_k) \) for \( \xi_n \)-almost all \( \gamma \) and all \( t \in (t_k, t_{k+1}) \), the bound (37) gives

\[
\mathbb{E}_{\xi_n} \left( \int_{t_k}^{t_{k+1}} |\gamma(t) - \gamma(t_k)| \, dt \right) = \Delta t_n (\Delta t_n)^{q + \frac{1}{q}} \left[ \mathbb{E}_{\xi_n} \left( \int_0^T |\gamma(t)|^q \, dt \right) \right]^{\frac{1}{q}} \leq C (\Delta t_n)^{1 + \frac{q}{q}},
\]

for some constant \( C > 0 \). Thus, by (62),

\[
\mathbb{E}_{\xi_n} \left( \int_0^T f(\gamma(t), M_n([t]_{\tau_n})) \, dt \right) = \mathbb{E}_{\xi_n} \left( \int_0^T f(\gamma(t), M_n([t]_{\tau_n})) \, dt \right) + o(1).
\]

The relation above and (59) yield

\[
\mathbb{E}_{\xi_n} \left( \int_0^T f(\gamma([t]_{\tau_n}), M_n([t]_{\tau_n})) \, dt \right) = \mathbb{E}_{\xi_n} \left( \int_0^T f(\gamma(t), m(t)) \, dt \right)
\]

\[
+ C \left( 1 + \sup_{t \in [0, T]} \mathbb{E}_{\xi_n}(|\gamma(t)|^q) \right) \sup_{t \in [0, T]} \omega(d_1(M_n([t]_{\tau_n}), m(t))) + o(1)
\]

\[
= \mathbb{E}_{\xi_n} \left( \int_0^T f(\gamma(t), m(t)) \, dt \right) + o(1),
\]

where, in the last equality, we have used (43) and the fact that \( M_n \to m \) in \( C([0, T]; P_1(\mathbb{R}^d)) \). Analogously,

\[
\mathbb{E}_{\xi_n} (g(\gamma(T), M_n(T))) = \mathbb{E}_{\xi_n} (g(\gamma(T), m(T))) + o(1).
\]
We say that \((\text{Section 2.5})\). The latter is given by measures on \(\Gamma\) in Definition 4.1, and the first order MFG system introduced by Lasry and Lions in \([24,19]\).

Therefore, passing to the limit \(n \to \infty\) in (60) and using (61), (63) and (64), we get

\[
E_{\xi^*}\left(\int_0^T [\ell(\gamma(t)) + f(\gamma(t), m(t))] \, dt + g(\gamma(T), m(T))\right) \leq E_{\xi^*}(u(\gamma(0), 0)).
\] (65)

Since, by definition,

\[ u(\gamma(0), 0) \leq \int_0^T [\ell(\gamma(t)) + f(\gamma(t), m(t))] \, dt + g(\gamma(T), m(T)) \quad \forall \gamma \in W^{1,2}([0, T]; \mathbb{R}^d), \]

inequality (65) implies that for \(\xi^*\)-almost all \(\gamma\) we have that

\[ u(\gamma(0), 0) = \int_0^T [\ell(\gamma(t)) + f(\gamma(t), m(t))] \, dt + g(\gamma(T), m(T)), \]

i.e. \(\xi^*\) is a MFG equilibrium for (25) (see Remark 4.3).

Finally, let us recall the relationship between the MFG equilibrium \(\xi^*\), defined in terms of probability measures on \(\Gamma\) in Definition 4.1, and the first order MFG system introduced by Lasry and Lions in [24, Section 2.5]. The latter is given by

\[
\begin{aligned}
-\partial_t u + H(\nabla u) &= f(x, m(t)) \quad \text{in } \mathbb{R}^d \times (0, T), \\
\partial_t m - \nabla H(\nabla u)m &= 0 \quad \text{in } \mathbb{R}^d \times (0, T), \\
u(\cdot, T) &= g(\cdot, m(T)) \quad \text{in } \mathbb{R}^d, \quad m(0) = m_0.
\end{aligned}
\] (MFG)

We say that \((u, m)\) solves \((MFG)\) if \(u\) is continuous, Lipschitz w.r.t. its first argument, \(m \in C([0, T]; P_1(\mathbb{R}^d))\), the first equation is satisfied in the viscosity sense and the second one is satisfied in the sense of distributions.

We will need the additional assumption

\((\text{H5})\) The following assertions hold true:

(i) The function \(\ell\) is \(C^2\), the growth condition (26) is satisfied with \(q = 2\), and for \(h = f, g\) we have that \(h(\cdot, m)\) is \(C^2\), for every \(m \in P_1(\mathbb{R}^d)\), and there exists \(C > 0\) such that

\[
\sup_{m \in P_1(\mathbb{R}^d)} \left\{ \|h(\cdot, m)\|_\infty + \|D_x h(\cdot, m)\|_\infty + \|D_{xx} h(\cdot, m)\|_\infty \right\} \leq C.
\] (66)

(ii) The initial distribution \(m_0\) is absolutely continuous and its density belongs to \(L^\infty(\mathbb{R}^d)\).

Under assumptions \((\text{H3})\) and \((\text{H5})\), there exists at least one solution \((u, m)\) to \((MFG)\) (see [24, 19]). Moreover, this solution is unique under the following monotonicity assumption on \(f\) and \(g\):

For \(h = f, g\), we have

\[
\int_{\mathbb{R}^d} [h(x, m) - h(x, m')] \, dm(m - m')(x) \geq 0 \quad \forall m, m' \in P_1(\mathbb{R}^d).
\] (67)

If \((u, m)\) is a solution of \((MFG)\), the results in [8, Chapter 6] imply that for almost all \(x \in \mathbb{R}^d\) the equality (48) holds and

\[
u(x, 0) = \int_0^T \left[ \ell(\gamma^x(t)) + f(\gamma^x(t), m(t)) \right] \, dt + g(\gamma^x(T), m(T)),
\] (68)

where \(\gamma^x\) is the unique solution to

\[
\dot{\gamma}(t) = -\nabla H(\nabla u(\gamma(t), t)) \quad t \in (0, T), \quad \gamma(0) = x.
\] (69)

Moreover, \(\gamma^x\) is the only curve in \(W^{1,2}([0, T]; \mathbb{R}^d)\) such that (68) holds. By considering a measurable selection of the set

\[
\{\gamma^x \in W^{1,2}([0, T]; \mathbb{R}^d) \mid \gamma^x \text{ satisfies (68), } x \in \mathbb{R}^d\},
\] (70)
Corollary 4.1. Suppose that (H3), (H4) and (H5) hold and that, as \( n \to \infty \), \( N_n^1/N_n^* \to 0 \) and \( \epsilon_n = o(1/ (N_n^1 \log(N_n^*))) \). Then, associated to every limit point \( m \) of \( (M_n) \) in \( C([0,T]; P_1(\mathbb{R}^d)) \) (there exists at least one), there exists \( u \in C(\mathbb{R}^d \times [0,T]) \), Lipschitz w.r.t. its first variable, and a subsequence of \( (M_n,U_n) \), which we still index by \( n \), such that \( (u,m) \) solves \( (MFG) \), \( M_n \to m \) in \( C([0,T]; P_1(\mathbb{R}^d)) \) and \( (U_n,u) \) satisfies (54).

Remark 4.4. Under the previous assumptions, the convergence results in Theorem 4.1 and in Corollary 4.1 hold for the entire sequence (i.e. without need of extracting a subsequence) if the solution to \( (MFG) \) is unique. This holds true under the following monotonicity assumption on \( h = f, g \) (see [24])

\[
\int_{\mathbb{R}^d} (h(x,m) - h(x,m')) \, d(m - m')(x) \geq 0 \quad \forall \ m, m' \in P_1(\mathbb{R}^d).
\]

4.2 Numerical simulations

In this section we provide some numerical results on the approximation of continuous first order MFG problems by finite ones in the one-dimensional case \( d = 1 \). Examples in higher dimension and other MFG models will be treated in a future work.

We consider an initial distribution \( \bar{m}_0 \) with a density, still denoted by \( \bar{m}_0 \), given by

\[
\bar{m}_0(x) := \begin{cases} 
    e^{-\frac{(x-0.75)^2}{0.02}} & \text{if } x \in [0,1] \\
    0 & \text{otherwise},
\end{cases}
\]

and a time horizon \( T := 1 \). Using the notations in the previous section, the function \( \ell \) that we consider is defined by \( \ell(\alpha) := \frac{1}{\alpha^2} \) for all \( \alpha \in \mathbb{R} \) and the functions \( f \) and \( g \) have the form

\[
f(x,m) = \alpha \rho_\sigma \ast \rho_\sigma * m(x) + F(x), \quad g(x,m) = \beta \rho_\sigma \ast \rho_\sigma * m(x) + G(x) \quad \forall \ x \in \mathbb{R}, \ m \in P_1(\mathbb{R}),
\]

where \( \alpha \) and \( \beta \) are non-negative constants, \( \rho_\sigma(z) := \frac{1}{\sqrt{2\pi\sigma}} e^{-z^2/2\sigma^2} \) for all \( z \in \mathbb{R} \) \((\sigma \neq 0)\), and \( F, G : \mathbb{R} \to \mathbb{R} \) will be specified below in the numerical tests that we will present. The convolution terms in the definition of \( f \) and \( g \) model the aversion of a typical agent to congested areas, whereas the functions \( F \) and \( G \) model the desirability of a typical agent to reach the minima of \( F \) and \( G \), respectively.

We fix the following discretization parameters

\[
\Delta x = 0.005, \quad \Delta t = 0.02, \quad \epsilon = 0.002,
\]

which are in accordance with the assumptions in Theorem 4.1, because \( \Delta x/\Delta t \) and \( \epsilon |\log(\Delta x)|/\Delta t \) are reasonably small. We consider the numerical solution of the finite MFG system (29) by using the fictitious play method (9). Since the initial distribution is very concentrated around \( x = 0.75 \), for numerical purposes we restrict the solution to (29) to grid points belonging to \([0,1]\). Denoting by \( \mathcal{S} \) this set, we approximate \( \bar{m}_0 \) by \( M_0 \in P(\mathcal{S}) \), defined as

\[
M_0(x) := \frac{e^{-\frac{(x-0.75)^2}{0.02}}}{\sum_{x' \in \mathcal{S}} e^{-\frac{(x'-0.75)^2}{0.02}}} \quad \forall \ x \in \mathcal{S}.
\]

Note that by [10, Example 1.1], the functions \( f \) and \( g \) in (71) satisfy (67), which in turns implies that their restrictions to \( \mathcal{S} \times P(\mathcal{S}) \) satisfy (H2)(i).
It will be useful to introduce the following notation. Given \( M \in \mathcal{P}(\mathcal{S}) \), we will denote by \( BR(M) \in \mathcal{P}(\mathcal{S}) \), the best response to \( M \), which is computed with the first two relations in (9). Indexing by \( n \) the iterations of the fictitious play method, in all the tests below we compare the resulting average measure \( \mathcal{M}_n \) versus its best response \( \mathcal{M}^{n+1} := BR(\mathcal{M}_n) \) for \( n \) large enough. We also compare the deviation between \( \mathcal{M}^{n+1} \) and \( \mathcal{M}^n \).

We have observed in the tests below that the numerical convergence of the fictitious play procedure is slow. A possible explanation of this fact is that (9) implies that \( (\mathcal{M}_n, \mathcal{M}^{n+1}) \) depends importantly on the initial measure \( \mathcal{M}^1 \), as, for every \( n \geq 1 \), the term \( \mathcal{M}^1/n \) is needed to compute \( \mathcal{M}_n \). Thus, loosely speaking, this implies that if we choose \( \mathcal{M}^1 \) quite arbitrary, then we should not expect a fast convergence. For this reason, we implement a variation of the fictitious play procedure that accelerates importantly the speed of convergence, at least in our tests. We underline, however, that a rigorous justification of the improvement of the speed of convergence for the modified algorithm is not provided here and remains as an open question for future research. The idea is to perform an internal iteration in order to update the “initial condition” whenever we find a better one. The modified algorithm reads as follows:

**Algorithm 1: Modified Fictitious Play**

As the reader will notice in the tests below, numerically the sequence

\[
\mathbb{N} \ni n \mapsto |\mathcal{M}^{n+1} - \mathcal{M}^n|_{L^1} := \frac{1}{\Delta t + 1} \sum_{k=0}^{\mathcal{T}} \sum_{x \in \mathcal{S}} |\mathcal{M}^{n+1}(x,k) - \mathcal{M}^n(x,k)| \in \mathbb{R},
\]

(72)

exhibits a monotone decreasing behaviour for the fictitious play method, while the corresponding behaviour for the modified version is not monotone but the convergence to zero is faster. On the other hand, we have found that the number of iterations to get a desired accuracy \( \beta \) for \( |\mathcal{M}^{n+1} - \mathcal{M}^n|_{L^1} \) is often lower for the fictitious play method than for its modified version. However, the quantity \( |\mathcal{M}^{n+1} - \mathcal{M}^n|_{L^1} \) measures better the convergence of the algorithm than the quantity \( |\mathcal{M}^{n+1} - \mathcal{M}^n|_{L^1} \), because if \( \mathcal{M}^{n+1} = \mathcal{M}^n \), then \( \mathcal{M}^{n+1} \) solves the finite MFG problem.
### 4.2.1 Test 1

We set $F(x) = 2(x - 0.2)^2$, $G \equiv 0$, $\alpha = 1$, $\beta = 0$ and $\sigma = 0.25$. Note that, because of the presence of the quadratic function $F$, the function $f$ does not satisfy condition (66). However, we can easily provide an extension of $[0, 1] \ni x \mapsto F(x) \in \mathbb{R}$ to a function defined in $\mathbb{R}$ such that (66) holds. Since in our examples most of the mass remains concentrated in the interval $[0, 1]$, for simplicity we do not consider this extension.

In Table 4.2.1 we provide the number of iterations needed to achieve different specified tolerances for $|M^{n+1} - M^n|_{L^1}$ and $|M^{n+1} - M^n|_{L^1}$ with the fictitious play method and its modified version. For $n = 10$, the resulting distributions $\overline{M}^n$ and $M^n$ are displayed in Figure 1, showing that both configuration differ considerably. The difference $|M^n - M^{n+1}|_{L^1}$, as a function of the number of iterations, is plotted in Figure 2. In Figure 3 we plot $\bar{M}^n$ and its best response $M^{n+1} = B(\bar{M}^n)$ for $n = 1000$ showing that both configurations are very similar.

| $|\bar{M}^n - M^{n+1}|_{L^1} < \beta$ | $|M^n - M^{n+1}|_{L^1} < \beta$ |
|---------------------------------|---------------------------------|
| \(\beta = 0.1\) | \(n = 37\) | \(n = 11 (\delta = 0.1)\) |
| \(\beta = 0.01\) | \(n = 547\) | \(n = 17 (\delta = 0.01)\) |
| \(\beta = 0.001\) | \(n = 6323\) | \(n = 25 (\delta = 0.001)\) |

Table 1: The minimum number of iterations in Test 1, for attaining the desired accuracy $\beta$ when the Fictitious Play (FP) and the Modified Fictitious Play (MFP) are implemented.

**Remark 4.5.** We also implemented the intuitive heuristic $M^{n+1} = \text{BR}(M^n)$ and we observed that convergence does not always occur. Indeed, we found that there are distributions $M$ satisfying $M = \text{BR}(\text{BR}(M))$ with $M \neq \text{BR}(M)$, confirming that we should not expect convergence using this type of scheme. In the current example we have found $|M^n - \text{BR}(M^n)|_{L^1} \approx 1.8$ for all $n$.

### 4.3 Test 2

In this example we set $F(x) = 2(x - 0.5)^2$, $G(x) = 2(x - 0.2)^2$, $\alpha = \beta = 1$. As in the previous test, the individual preference is to approach the state $x = 0.5$ and to avoid congested areas during the time interval $(0, 1)$. However, in addition to these preferences, the individuals aim to approach the point $x = 0.2$ at the final time $t = 1$. We provide the numerical results in Table 4.3, which shows again a very good performance of the modified fictitious play procedure. We also plot in Figure 4 the distribution $\bar{M}^n$ and its best response $M^{n+1} := \text{BR}(\bar{M}^n)$ for $n = 1000$.

| $|\bar{M}^n - M^{n+1}|_{L^1} < \beta$ | $|M^n - M^{n+1}|_{L^1} < \beta$ |
|---------------------------------|---------------------------------|
| \(\beta = 0.1\) | \(n = 81\) | \(n = 48 (\delta = 0.1)\) | \(n = 4\) | \(n = 34 (\delta = 0.1)\) |
| \(\beta = 0.01\) | \(n = 962\) | \(n = 65 (\delta = 0.01)\) | \(n = 20\) | \(n = 50 (\delta = 0.01)\) |
| \(\beta = 0.001\) | \(n = 9830\) | \(n = 121 (\delta = 0.001)\) | \(n = 49\) | \(n = 83 (\delta = 0.001)\) |

Table 2: The minimum number of iterations in Test 2, for attaining the desired accuracy $\beta$ for classical Fictitious Play (FP) and Fast Fictitious Play (FFP).
Figure 1: Comparing $M^n$ (left) versus its best response $M^{n+1}$ (right), at step $n = 10$.

Figure 2: The distance between $M^n$ and its best response $M^{n+1}$. FP (left) versus MFP (right).

Figure 3: Comparing $M^n$ (left) versus its best response $M^{n+1}$ (right), at step $n = 1000$. 

Figure 4: Comparing $M^n$ (left) versus its best response $M^{n+1}$ (right), at step $n = 1000.$
