HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Abstract—We present an adaptive observer for linear time-varying systems whose state matrix depends on unknown parameters. We first assume that the state matrix is affine in these parameters. In this case, the proposed observer generates state and parameter estimates, which exponentially converge to the plant state and the true parameter, respectively, provided a persistence of excitation condition holds and the unknown parameters lie in a neighborhood of some known nominal values. Hence, some prior knowledge on the unknown parameters is required, but not on the state. We then modify the adaptive observer and its convergence analysis to systems whose state matrix is smooth, instead of being affine, in the unknown parameters. The convergence is approximate, and no longer exponential, in this case. An example is provided to illustrate the results, for which the required distance between the unknown parameters and their nominal values is investigated numerically.

I. INTRODUCTION

The objective of this work is to estimate both the state and the parameters of the system

\[ \begin{align*}
\dot{x}(t) &= A(t, \theta)x(t) + B(t)u(t) \\
y(t) &= C(t)x(t),
\end{align*} \]

where \( x(t) \in \mathbb{R}^n \) is the state, \( u(t) \in \mathbb{R}^n \) is the input, \( y(t) \in \mathbb{R}^m \) is the output, \( \theta \in \mathbb{R}^n \) is the vector of unknown constant parameters, \( t \geq 0 \) is the time, and \( n_x, n_u, n_y, n_{\theta} \in \mathbb{Z}_{>0} \). In other words, we aim at designing an adaptive observer for system (1). This problem arises in many practical applications, including electrochemical batteries [11] or mechanical systems [7] to cite a couple of examples, as soon as we need to estimate on-line both the unmeasured state and unknown parameters of a plant for monitoring purposes for instance.

In the majority of works on adaptive observers, the state matrix is assumed to be fully known contrary to (1), and the unknown parameters enter in the system through an additional term of the form \( \Phi(t, u(t), y(t))\theta \) where \( \Phi \) is known. Solutions for this case can be found in e.g., [1], [2], [17], [24]–[26]. The fact that \( A \) depends on \( \theta \) in (1) is a major difference with these references, which makes the problem difficult because of the cross-terms involving \( \theta \) and \( x(t) \). There are nevertheless results in the literature, which propose adaptive observers for systems with partially unknown state matrix \( A \). In [14], several designs are given for single-input single-output linear time-invariant (LTI) systems. In [15], it is explained how to optimally fit a discrete-time LTI model to any given output signals. In [18], a switched approach is proposed for LTI systems based on linear matrix inequalities (LMI) conditions. More recently, a generic approach for the state and parameter estimation of nonlinear systems was presented in [6] using a multi-observer set-up. On the other hand, adaptive observers for systems with known state matrices with an additive term of the form \( \Phi(x)\theta \) (see e.g., [3], [5], [9], [10]) are relevant in this context when \( A \) is affine in \( \theta \), as a simple manipulation brings system (1) to the right form.

In this work, we propose an approach, which relies on a simple idea. We essentially assume that we know a state-observer for system (1) for some known nominal parameter value \( \theta_0 \). Because \( \theta \neq \theta_0 \), the idea is to modify the original state-observer and design an adaptation law to estimate \( \theta \) by relaying on similar techniques as in [26]. Indeed, by adding and subtracting \( A(t, \theta_0)x(t) \) in the first equation in (1), we obtain \( \dot{x}(t) = A(t, \theta_0)x(t) + B(t)u(t) + \left[A(t, \theta) - A(t, \theta_0)\right]x(t) \). Assuming \( A(t, \theta) \) is affine in \( \theta \) we can write \( A(t, \theta)x(t) - A(t, \theta_0)x(t) = \Lambda(t, x(t))(\theta - \theta_0) \), where \( \Lambda(t, x(t)) \) is a time-varying matrix linear in its second argument; this is explained in more detailed in the sequel.

Hence, \( \dot{x}(t) = A(t, \theta_0)x(t) + B(t)u(t) + \Lambda(t, x(t))(\theta - \theta_0) \).

Denoting by \( \hat{x} \) the state estimate of the adaptive observer to be designed and \( \tilde{x} = x - \hat{x} \) the associated state estimation error, we derive \( \dot{\tilde{x}}(t) = A(t, \theta_0)x(t) + B(t)u(t) + \Lambda(t, \tilde{x}(t))(\theta - \theta_0) + \Lambda(t, \tilde{x}(t))(\theta - \theta_0) \), since \( \Lambda \) is linear in its second argument. Now \( \Lambda(t, \tilde{x}(t)) \) is known since \( \hat{x} \) is the state estimate we generate. The term \( \Lambda(t, \tilde{x}(t))(\theta - \theta_0) \) is therefore of the form \( \Phi(t)(\theta - \theta_0) \) where \( \Phi(t) \) is known. We are almost back to the same class of systems as in [26] where the unknown parameter is \( \theta - \theta_0 \) instead of \( \theta \), but this is fine since we know \( \theta_0 \). The difference with [26] is that we have to deal with the extra term \( \Lambda(t, \tilde{x}(t))(\theta - \theta_0) \). It appears that when \( ||\theta - \theta_0|| \) is small, so is \( \Lambda(t, \tilde{x}(t))(\theta - \theta_0) \tilde{x}(t) \) so that stability of the estimation error may be ensured. The point of these developments is to show that after some simple manipulations, we can write the problem in a similar, though different form, as in [26]. Still, the design of the adaptive observer is not a straightforward application of [26] and requires appropriate modifications as well as specific assumptions. The exponential convergence of the proposed adaptive observer is guaranteed provided a persistence of excitation condition holds and \( ||\theta - \theta_0|| \) is small enough. Such an excitation condition is needed in almost all works on adaptive observers. The fact that \( ||\theta - \theta_0|| \) has to be small
means that the design is local in the parameter estimate, but we are free to initialize the state estimate as we wish. It can be noted that many estimation or identification schemes are also local, see [15] for instance and all the works on extended Kalman filters, see e.g., [4], [13], [21]. Afterwards, the results are extended to the case where \( A \) is only smooth in \( \theta \), and not necessarily affine. The adaptive observer and its analysis are modified accordingly and an approximate convergence property is ensured in this case.

Compared to [14], our results apply to multi-input multi-output linear time-varying systems, as opposed to single-input single-output LTI systems, and compared to [18], we address LTV systems and our approach relies on different type of conditions (no LMI). The closest work in spirit, although it is written in discrete-time for LTI models, is the one in [15]. A key difference with [15] is that we do not need to use projection techniques to maintain the parameter estimate in some given set, and the estimates we generate cannot be trapped in the border of the given set due to projections, but always converge to the true parameter provided, again, that \( ||\theta - \theta_0|| \) is small enough and a persistence of excitation holds. On the other hand, the adaptive observer is less computationally demanding than the supervisory observer presented in [6], which requires a large number of observers to work, and we ensure the asymptotic convergence of the estimation errors as opposed to a practical property in [6]. Finally, compared to [3], [5], [9], [10]: (i) we do not require any particular triangular or block-diagonal structure of the system ([3], [9], [10]); (ii) we provide results for the case where the state matrix is not affine in \( \theta \) in which case the results in [3], [5], [9] do not apply; (iii) we do not rely on high-gain techniques ([9], [10]), which are not known to be very sensitive to noise measurements; (iv) the observer is of smaller dimension, which is relevant for computational reasons ([3], [9], [10]). Also, we believe that the way we approach the problem has its own interest, which can be relevant for further extensions.

A similar problem is addressed in [7]. First, exponential convergence is ensured in our case when \( A \) is affine in \( \theta \) as opposed to an ultimate boundedness property in [7]. Second, the proposed solution is computationally lighter, since [7] requires the use of both a state-observer for the nominal parameter values and of an adaptive observer, while we only need the latter.

Some proofs are omitted for space reasons, these can be found in [20].

**Notation and terminology.** Let \( \mathbb{R} := (-\infty, \infty) \), \( \mathbb{R}_{>0} := [0, \infty) \), \( \mathbb{R}_{\geq 0} := (0, \infty) \), \( \mathbb{Z}_{>0} := \{0, 1, 2, \ldots\} \), and \( \mathbb{Z}_{\geq 0} := \{1, 2, \ldots\} \). The notation \( (x, y) \) stands for \( [x^T, y^T]^T \), where \( x \in \mathbb{R}^n \), \( y \in \mathbb{R}^m \), and \( n, m \in \mathbb{Z}_{>0} \). The identity matrix of size \( n \in \mathbb{Z}_{>0} \) is denoted \( I_n \) or simply \( I \) when the dimension is clear from the context. Given two matrices \( Q, R \in \mathbb{R}^{n \times n} \), we write \( Q \leq R \) if \( R - Q \) is positive semi-definite, \( n \in \mathbb{Z}_{>0} \). The symbol \( * \) stands for symmetric blocks in matrices. A time-varying matrix \( M(t) \in \mathbb{R}^{n \times m} \) is said to be bounded if there exists \( c \geq 0 \) such that \( ||M(t)|| \leq c \) for any \( t \geq 0 \), where \( ||M(t)|| := \sup_{x \in \mathbb{R}^n \setminus \{0\}} \frac{||M(t)x||}{||x||} \) standing for the Euclidean norm when the argument is a vector. We write \( N(x) = \mathcal{O}(||x||^p) \) for \( N : \mathbb{R}^n \to \mathbb{R}^m \) with \( n, m \in \mathbb{Z}_{>0} \), when there exists \( c \geq 0 \) such that \( ||N(x)|| \leq c||x||^p \) for any \( x \in \mathbb{R}^n \). The set of piecewise continuous functions from \( \mathbb{R}_{\geq 0} \) to \( \mathbb{R}^n \) is denoted \( \mathcal{PC}(\mathbb{R}^n) \), \( n \in \mathbb{Z}_{>0} \). Let \( p \in \mathbb{R}^n \) and \( \delta \in \mathbb{R}_{\geq 0} \cup \{\infty\} \), the closed ball of radius \( \delta \) centered at \( p \) is denoted \( \mathbb{B}(p, \delta) \), with \( \mathbb{B}(p, \delta) = \mathbb{R}^n \) when \( \delta = \infty \).

**II. Assumptions**

The matrices \( A(t, \theta) \), \( B(t) \) and \( C(t) \) in (1) are assumed to be continuous and bounded with respect to the time \( t \). We make the next assumption on how \( A(t, \theta) \) depends on \( \theta \).

**Assumption 1:** The matrix \( A(t, \theta) \) is affine in \( \theta \), in the sense that there exist matrices \( A_0(t), \ldots, A_{n_{\theta}}(t) \in \mathbb{R}^{n_x \times n_{\theta}} \) such that, for any \( t \geq 0 \), \( A(t, \theta) = A_0(t) + \sum_{i=1}^{n_{\theta}} A_i(t)\theta_i \), where \( \theta = (\theta_1, \ldots, \theta_{n_{\theta}}) \).

When Assumption 1 is not satisfied, we may redefine the vector of unknown parameters to enforce it, by eventually over-parameterizing the original system. This assumption will be relaxed in Section III-C. It is important to note that the matrices \( A_0(t), \ldots, A_{n_{\theta}}(t) \) in Assumption 1 are known, as these can be directly derived from the expression of \( A(t, \theta) \). These matrices are continuous and bounded with respect to the time since so is \( A(t, \theta) \).

Our design implicitly relies on the knowledge of a state observer for system (1) if \( \theta \) would be known. More precisely, we make the following assumption.

**Assumption 2:** There exist \( \delta_1 \in \mathbb{R}_{\geq 0} \cup \{\infty\} \) and \( K : \mathbb{R}_{\geq 0} \times B(\theta, \delta_1) \to \mathbb{R}^{n_x \times n_{\theta}} \), which is continuous and bounded, such that for any \( \theta_0 \in B(\theta, \delta_1) \) the origin of the system \( \dot{x}(t) = [A(t, \theta_0) - K(t, \theta_0)C(t)] \dot{x}(t) \) is uniformly globally exponentially stable.

Assumption 2 essentially means that we know a set where parameter \( \theta \) lies and, if we knew \( \theta \), we would be able to design a state-observer for the corresponding system. More precisely, Assumption 2 states that there exists a neighborhood of parameter \( \theta \), corresponding to \( B(\theta, \delta_1) \), such that we can design a standard (Luenberger) state observer with gain \( K(t, \theta_0) \) for any \( \theta_0 \) in this set, whose solutions uniformly, globally, and exponentially converge to solutions to (1) when \( \theta = \theta_0 \). To see it, let \( \tilde{x}(t) = A(t, \theta_0)x(t) + B(t)u(t) + K(t, \theta_0)(y(t) - C(t)\tilde{x}(t)) \). If \( \theta = \theta_0 \), then the estimation error system with variable \( \dot{x} = x - \tilde{x} \) is \( \dot{x}(t) = [A(t, \theta_0) - K(t, \theta_0)C(t)] \dot{x}(t) \) as in Assumption 2.

A necessary and sufficient condition for Assumption 2 to hold is provided next.

**Lemma 1:** Under Assumption 1, Assumption 2 holds if and only if there exists a continuous and bounded mapping \( K^* : \mathbb{R}_{\geq 0} \to \mathbb{R}^{n_x \times n_{\theta}} \) such that the origin of \( \dot{x}(t) = [A(t, \theta) - K^*(t)(C(t)] \dot{x}(t) \) is uniformly globally exponentially stable for the (unknown) true parameter value \( \theta \).

Lemma 1 involves \( \theta \), which we do not know. The following lemma provides exploitable conditions for the satisfaction of Assumption 2.

**Lemma 2:** Suppose the following holds.

(i) Assumption 1 holds.
(ii) There exists $\delta_1 \in \mathbb{R}_{>0} \cup \{\infty\}$ such that the pair $(A(t, \theta_0), C(t, \theta_0))$ is uniformly completely observable\(^2\) for any $\theta_0 \in B(\theta, \delta_1)$.

Assumption 2 is verified with $K(t, \theta_0) = P(t, \theta_0)C(t) + R(t)$ where $P(t, \theta_0)$ is the solution to the Riccati equation

$$
\dot{P}(t, \theta_0) = P(t, \theta_0)A(t, \theta_0) + A(t, \theta_0)^T P(t, \theta_0) - P(t, \theta_0) C(t) C(t)^T P(t, \theta_0) + Q(t), \quad P(0) = P_0,
$$

where $P_0$ is any symmetric, positive definite matrix, and $R(t), Q(t)$ are any symmetric, positive definite, continuous and bounded matrices.

When the matrices $A$ and $C$ in (1) are time-invariant, it suffices to have the pair $(A(\theta_0), C(\theta_0))$ observable for any $\theta_0$ such that $||\theta - \theta_0|| \leq \delta_1$ for some $\delta_1 \in \mathbb{R}_{>0} \cup \{\infty\}$ to ensure Assumption 2. Indeed, in this case, Buss-Gaura formula\(^3\) leads to a gain $K(\theta_0)$, which is continuous in $\theta_0$.

The same applies when $L(\theta_0)$ is selected to minimize a linear quadratic cost, i.e. when $L(\theta_0) = \theta_0^T P(\theta_0) \theta_0$ is the solution to the Riccati equation $\dot{P}(\theta_0) = P(\theta_0)A(\theta_0)^T + A(\theta_0)P(\theta_0) - P(\theta_0)C(\theta_0)C(\theta_0)^T P(\theta_0) + Q(\theta_0)$. It suffices to select $Q$ and $R$ symmetric and positive definite to ensure the continuity of $P(\theta_0)$ in $\theta_0$ according to Proposition 1 in [8], which in turn implies the continuity of $K(\theta_0)$ in $\theta_0$.

We finally make the next boundedness assumption on system (1).

**Assumption 3:** There exists a hyper-rectangle $\mathcal{X} = \{x = (x_1, \ldots, x_{n_x}) \in \mathbb{R}^{n_x} : x_i \in [c_i, \bar{c}_i], i \in \{1, \ldots, n_x\}\}$ such that $\bar{c}_i \leq \bar{c}_i \in \mathbb{R}$, $i \in \{1, \ldots, n_x\}$, a non-empty set of inputs $\mathcal{M}_u \subset \mathcal{P}(\mathbb{R}^{n_u})$, and a non-empty set of initial conditions $\mathcal{S}_X \subset \mathbb{R}^{n_x}$, such that any solution $x$ to system (1) initialized in $\mathcal{S}_X$ with input $u \in \mathcal{M}_u$ satisfies $x(t) \in \mathcal{X}$ for all $t \geq 0$.

Assumption 3 means that the solutions to (1) lie in a known compact set, which can always be embedded in a closed hyper-rectangle, whenever its input lies in set $\mathcal{M}_u$.

Note that there is no restriction of the “size” of $\mathcal{X}$.

### III. MAIN RESULT

#### A. Design and analysis

Like in [22], we introduce the element-wise saturation function $\sigma_X : \mathbb{R}^{n_x} \rightarrow \mathbb{R}^{n_x}$ defined as $\sigma_X(x) := (\sigma_1(x_1), \ldots, \sigma_{n_x}(x_{n_x}))$ with $\sigma_i(x_i) = x_i$ when $x_i \in [c_i, \bar{c}_i]$, $\sigma_i(x_i) = \bar{c}_i$ when $x_i \leq c_i$ and $\sigma_i(x_i) = c_i$ when $x_i \geq \bar{c}_i$, for any $x \in \mathbb{R}$, where $\mathcal{X}, \mathcal{U}, \mathcal{T}_i$ come from Assumption 3, $i \in \{1, \ldots, n_x\}$. Based on Assumptions 1-2 and inspired by [26], we propose the adaptive observer

$$
\dot{x}(t) = A(t, \theta_0)x(t) + B(t)u(t) + \Lambda(t, \sigma_X(x(t)))\hat{\theta}(t) + K(t, \theta_0) + \gamma \dot{\theta}(t)\dot{Y}(t)
$$

$$
+ C(t)\hat{x}(t)\dot{\theta}(t) = \gamma \dot{Y}(t)\mathcal{C}(\mathcal{T}(t)\mathcal{C}(t)^T(t)\mathcal{S}(t))\delta(t)
$$

$$
\dot{Y}(t) = [A(t, \theta_0) - K(t, \theta_0)C(t)]\mathcal{Y}(t) + \Lambda(t, \sigma_X(x(t)))
$$

$$
\dot{\theta}(t) = \hat{\theta}(t) + \theta_0,
$$

where $\hat{\theta}(t) \in \mathbb{R}^{n_\theta}$ is the estimate of $\theta - \theta_0$, $\hat{\theta}(t) \in \mathbb{R}^{n_\theta}$ is therefore the estimate of $\theta$, $\mathcal{Y}(t) \in \mathbb{R}^{n_x \times n_\theta}$.

\(2\)See [23] for a definition of uniform complete observability as well as conditions to ensure it.

\(3\)See Chapter 4 in [12] for instance.

### Remark 1: The use of the saturation function $\sigma_X$ in (2) is essential to guarantee the boundedness of $\mathcal{Y}$ in the proof of the next theorem, which is needed to establish the desired convergence property. This is the main difference with [26] in terms of design. Other differences reside in the assumptions we rely on.

The next theorem ensures that the state and the parameter estimates provided by (2) exponentially converges to $x$ and $\theta$, provided a persistence of condition holds and $||\theta - \theta_0||$ is sufficiently small. Its proof is provided in Section III-B.

**Theorem 1:** Consider systems (1) and (2) and suppose the following holds.

(i) Assumptions 1-3 hold.

(ii) Let $\delta_2 \in \mathbb{R}_{>0} \cup \{\infty\}$, $\bar{x}_0 \in \mathbb{R}^{n_x}$, $\tilde{\mathcal{Y}}_0 \in \mathbb{R}^{n_x \times n_\theta}$, $\bar{\mathcal{Y}}_0 \in \mathbb{R}^{n_x \times n_\theta}$, there exist $a, T > 0$, which depend on $\bar{x}_0, \tilde{\mathcal{Y}}_0, \bar{\mathcal{Y}}_0$, such that, for any $x(0) \in \mathcal{S}_X$ and input $u \in \mathcal{M}_u$, any $\theta_0$ such that $||\theta - \theta_0|| \leq \delta_2$, the solution $\hat{x}(t), \hat{\mathcal{Y}}(t)$ to system (2) initialized at $(\bar{x}_0, \tilde{\mathcal{Y}}_0, \bar{\mathcal{Y}}_0)$ with $||\theta_0 - \theta|| \leq \delta_2$, verifies for any $t \geq 0$.

$$
\alpha \leq \int_{t_0}^{t_0 + T} \dot{\mathcal{Y}}(t) = \mathcal{C}(t)\mathcal{T}(t)\mathcal{S}(t)\mathcal{C}(t)\mathcal{Y}(t)dr.
$$

There exist $\delta \in (0, \min\{\delta_1, \delta_2\})$ and $c_1, c_2 > 0$ , which depend on $\mathcal{X}, \mathcal{M}_u, \bar{x}_0, \tilde{\mathcal{Y}}_0, \bar{\mathcal{Y}}_0$, such that, if $||\theta - \theta_0|| \leq \delta$, the solution $(\tilde{x}(t), \tilde{\mathcal{Y}}(t))$ to (2) initialized at $(\bar{x}_0, \tilde{\mathcal{Y}}_0, \bar{\mathcal{Y}}_0)$ and any solution to system (1) with $x(0) \in \mathcal{S}_X$ and input $u \in \mathcal{M}_u$, verify $||x(t) - \tilde{x}(t), \theta(t) - \theta|| \leq c_1 e^{-\gamma t}||x(0) - \bar{x}_0, \theta(0) - \theta||$ for any $t \geq 0$.

Item (ii) of Theorem 1 is a persistence of excitation condition on the system, like in [26]. It actually is a uniform persistence of excitation property, see Definition 2 in [16], as the constants $a$ and $T$ are independent of $\theta_0$, which is essential. Indeed, if the bound $\delta_2$, and thus $\delta$, on the norm of $\theta - \theta_0$ would depend on $\theta_0$, there will be no guarantee that we can always select $\theta_0$ sufficiently close to $\theta$ such that $||\theta - \theta_0|| \leq \delta$. That is also the reason why we assume the existence of the gain $K(t, \theta_0)$ for any $\theta_0 \in B(\theta, \delta_1)$ in Assumption 2, and not for a given $\theta_0$, otherwise $\delta_1$ in Assumption 2 may depend on $\theta_0$ and the same issue would arise. On the other hand, $\delta$ depends on the initial conditions of observer (2). It is possible to ensure that $\delta$ is uniform over these initial conditions over given sets, when (3) holds for any initial conditions in these sets.

Property (3) is difficult to verify as it involves any $\theta_0$ in a set, and any solution initialized in $\mathcal{S}_X$ with input $u \in \mathcal{M}_u$. Even if we could verify it, that would not mean that the estimates converge to the true values, as we also need for
that $||\theta - \theta_0||$ to be sufficiently small, which is something we cannot check in practice. It is important to note that this difficulty is generic to any local estimation schemes, including works on extended Kalman filters where the initial conditions $x_0$ and $\theta_0$ have to be close to each other (among other conditions), see e.g., [4], [13], [21]. The only way to avoid it is when we have the property that the observation error $y(t) - C(x(t))$ converging to zero implies that the estimation errors $x(t) - \hat{x}(t)$ and $\theta - \hat{\theta}(t)$ also converging to zero, see Section III.A in [19]. In practice, we can check numerically on-line whether the inequality in (3) holds for a given $\theta_0$ and a given solution $x$ to (1), in which case the non-satisfaction of (3) indicates that the obtained estimate are not valid.

The fact that we need to know a set where the unknown parameters lie is a valid assumption in various applications, like electrochemical batteries for which the parameters are accurately known when the battery is produced, but slowly vary with time. Then, the interest of the adaptive observer is to track these slow variations for monitoring purposes. If we only have some vague knowledge about $\theta$, we may overcome this issue by employing a multi-observer architecture as explained in [19].

B. Proof of Theorem 1

We introduce the estimation errors $\tilde{x} := x - \hat{x}$ and $\tilde{\theta} := \theta - \theta_0 - \hat{\theta}$.

Let $x(t) \in \mathbb{R}^n$, $t \geq 0$ for which the solution to (1), (2) is defined, and $\theta_0 \in B(\theta, \min\{\delta_1, \delta_2\})$ where $\delta_1, \delta_2$ come from Assumptions 2 and (ii) of Theorem 1, respectively. In view of (1) and (2),

$$\dot{\tilde{x}}(t) = A(t, \theta)x(t) + B(t)u(t) - A(t, \theta_0)\tilde{x}(t) - B(t)u(t) - \Lambda(t, x(t))\tilde{\theta}(t) - [K(t, \theta_0)
+ \gamma \Upsilon(t)^T(t)C^T(t)\Sigma(t)(y(t) - C(t)\tilde{x}(t))],$$

we add and subtract $A(t, \theta_0)x(t)$ and we obtain

$$\dot{\tilde{x}}(t) = A(t, \theta_0) - K(t, \theta_0)C(t)\tilde{x}(t) - \Lambda(t, \theta_0)|\dot{x}(t)| \tilde{\theta}(t) - [K(t, \theta_0)
+ \gamma \Upsilon(t)^T(t)C^T(t)\Sigma(t)(y(t) - C(t)\tilde{x}(t))].$$

In view of Assumption 1 and the definition of $\Lambda(\cdot, \cdot)$ given after (2), $|A(t, \theta) - A(t, \theta_0)|x(t) = \Lambda(t, x(t))(\theta - \theta_0)$.

We now restrict our attention to the case where $x(t) \in S_X$ with $u \in \mathcal{M}_u$. Hence, $x(t) \in S_X$ and $x(t) = \sigma_X(x(t))$ in view of Assumption 3 and the definition of $\sigma$, respectively. Thus $|A(t, \theta) - A(t, \theta_0)|x(t) = \Lambda(t, \sigma_X(x(t)))(\theta - \theta_0)$.

Consequently, in view of (5),

$$\dot{\tilde{x}}(t) = A(t, \theta_0) - K(t, \theta_0)C(t)\tilde{x}(t) - \Lambda(t, \sigma_X(x(t)))(\theta - \theta_0) - \Lambda(t, \sigma_X(x(t))|\dot{x}(t)|\tilde{\theta}(t)
- [K(t, \theta_0)
+ \gamma \Upsilon(t)^T(t)C^T(t)\Sigma(t)(y(t) - C(t)\tilde{x}(t))].$$

We add and subtract $A(t, \theta_0)\tilde{x}(t)$ and $\theta_0$ we obtain, by exploiting the linearity of $\Lambda(\cdot, \cdot)$ in its second argument and using $\tilde{\theta}(t) = \theta - \theta_0 - \hat{\theta}(t)$,

$$\dot{\tilde{x}}(t) = A(t, \theta_0) - K(t, \theta_0)C(t)\tilde{x}(t) - \Lambda(t, \sigma_X(x(t)))(\theta - \theta_0)
+ \Lambda(t, \sigma_X(\tilde{x}(t))|\dot{\tilde{x}}(t)|\tilde{\theta}(t)
- [K(t, \theta_0)
+ \gamma \Upsilon(t)^T(t)C^T(t)\Sigma(t)(y(t) - C(t)\tilde{x}(t))].$$

Like in [26], we introduce $\eta := \tilde{x} - \Upsilon\tilde{\theta}$. We deduce from the last equation and (2),

$$\dot{\eta}(t) = [A(t, \theta_0) - K(t, \theta_0)C(t)]\dot{\tilde{x}}(t) + \Lambda(t, \sigma_X(x(t)) - \sigma_X(\tilde{x}(t)))(\theta - \theta_0) + \Lambda(t, \sigma_X(\tilde{x}(t))|\dot{\tilde{x}}(t)|\tilde{\theta}(t)
- \gamma \Upsilon(t)^T(t)C^T(t)\Sigma(t)(y(t) - C(t)\tilde{x}(t))
- [[A(t, \theta_0) - K(t, \theta_0)C(t)]\Upsilon(t) + \Lambda(t, \sigma_X(\tilde{x}(t)))]
\times\tilde{\theta}(t) + \Upsilon(t)^T(t)\gamma \Upsilon(t)^T(t)C^T(t)\Sigma(t)(y(t) - C(t)\tilde{x}(t))$$

$$= [A(t, \theta_0) - K(t, \theta_0)C(t)]\eta(t)
+ \Lambda(t, \sigma_X(x(t)) - \sigma_X(\tilde{x}(t)))(\theta - \theta_0).$$

(8)

On the other hand, in view of (2) and since $\tilde{x}(t) = \eta(t) + \Upsilon(t)\tilde{\theta}(t)$,

$$\tilde{\theta}(t) = -\gamma \Upsilon(t)^T(t)\Upsilon(t)^T(t)\Sigma(t)(y(t) - C(t)\tilde{x}(t)) = -\gamma \Upsilon(t)^T(t)\Upsilon(t)\Sigma(t)(y(t) - C(t)\tilde{x}(t))\Upsilon(t)^T(t)\theta(t) + \eta(t).$$

(9)

The dynamics of the $(\eta, \tilde{\theta})$-system in (8), (9) is the same as in (14)-(15) in [26] up to the perturbative term $\Lambda(t, \sigma_X(x(t)) - \sigma_X(\tilde{x}(t)))(\theta - \theta_0)$ in (8). Because of the latter, we can no longer invoke cascade arguments to conclude about the stability of the $(\eta, \tilde{\theta})$-system as in [26]. We will use small-gain arguments instead, and the small-gain condition will be enforced by imposing $\theta - \theta_0$ to be small, which explains why the convergence property we will guarantee is local and not global (in general).

Let $(\tilde{x}, \tilde{\theta}, \Upsilon)$ be the solution to system (2) initialized at $(x_0(t), \theta_0)$. We define $P : \mathbb{R}_{\geq 0} \times \mathbb{R}^{n_x} \rightarrow \mathbb{R}^{n_x \times n_x}$ as the solution to $\dot{P}(t, \theta_0) = P(t, \theta_0)[A(t, \theta_0) - K(t, \theta_0)C(t)] + [A(t, \theta_0) - K(t, \theta_0)C(t)]^T P(t, \theta_0) + \Xi$, with $P(0, \theta_0) = P_0$ and $P_0$ is symmetric and positive definite. Since $\theta_0$ belongs to the closed ball $B(\theta, \delta_1)$, Assumption 2 holds and $A(t, \theta_0) - K(t, \theta_0)C(t)$ is continuous and bounded, Lemma 1 in [16] ensures that $P(t, \theta_0)$ exists for all $t \geq 0$, is continuously differentiable, bounded, symmetric, positive definite and there exist $\alpha_P, \pi_P > 0$, which are independent of $\theta_0$, such that $\|P(t, \theta_0) - \pi_P I\| \leq \pi_P I$ for any $t \geq 0$. We define $V : (P, \eta) \rightarrow \mathbb{R}^{n_x} P \eta$. Let $t \geq 0$, in view of (8) and the definition of $P(t, \theta_0)$ (we omit the time and $\theta_0$ dependencies of the solutions), $V(P, \eta) = -||\eta||^2 + 2\eta^T P \Lambda(t, \sigma_X(x) - \sigma_X(\tilde{x}))(\theta - \theta_0)$, where $\tilde{x} := x - \Upsilon\theta$. The definition of $\Lambda(\cdot, \cdot)$ and the fact that the matrices $A_1(t), \ldots, A_n(t)$ are bounded according to Assumption 1 imply that there exists a constant $a_\Lambda > 0$ such that $||\Lambda(t, z)|| \leq a_\Lambda|z|$ for any $z \in \mathbb{R}^n$. Consequently, since $\Sigma \leq \pi_P I$, we have $V(P, \eta) \leq -||\eta||^2 + 2\eta^T \Sigma A \eta||\eta|| \cdot ||x(t) - \sigma_X(\tilde{x})|| \times ||\theta - \theta_0||$. From the definition of $\sigma$, $||x(t) - \sigma_X(\tilde{x})|| \leq n_x^2|\tilde{x}| = n_x|\tilde{x}||\tilde{x}|$, we deduce $n_x \eta||\eta|| + n_x ||\Upsilon|| ||\theta - \theta_0||$. Thus,

$$V(P, \eta) \leq -||\eta||^2 + 2n_x \pi_P A \eta||\eta|| \cdot ||\Upsilon|| \cdot ||\theta - \theta_0||$$

$$- [1 - 2n_x \pi_P A \eta||\eta|| \cdot ||\Upsilon|| \cdot ||\theta - \theta_0||]||\eta||^2 + 2n_x \pi_P A \eta||\eta|| \cdot ||\Upsilon|| \cdot ||\theta - \theta_0||$$

$$\times ||\theta - \theta_0||.$$
We now investigate the $\hat{\theta}$-system in (9). We need the next claim for that purpose.

Claim 1: There exists a continuous function $\nu : \mathbb{R}^{n_{x} \times n_{a}} \to [1, \infty)$, which is independent of $\theta_0$, such that for any continuous function $\hat{x} : \mathbb{R}_{\geq 0} \to \mathbb{R}^{n_x}$, the corresponding solution $\Upsilon$ to the $\Upsilon$-system in (2) initialized at $\Upsilon_0$ is such that $||\Upsilon(t)|| \leq \nu(\Upsilon_0)$ for any $t \geq 0$.

**Proof of Claim 1.** The result follows from Assumption 2, Lemma 1 in [16] and the fact that $\Lambda(t, \sigma_X(\hat{x}))$ is bounded uniformly with respect to $\theta_0 \in \mathcal{B}(\theta, \min\{\delta_1, \delta_2\})$. The fact that the image of $\nu$ is in $[1, \infty)$ can always be ensured by adding 1 to any bound on $||\Upsilon(t)||$.

The matrix $\gamma \Upsilon^T(t)C(t)\Sigma(t)(C(t)\Upsilon(t))$ is continuous and bounded since $\Sigma(t)$ is a constant, which will be selected below. In view of (10) and (11), the solution $\hat{P}(t)$ to $\hat{P}(t) = -\gamma \hat{P}(t)\Upsilon^T(t)C(t)\Sigma(t)(C(t)\Upsilon(t))\hat{P}(t) + I$, with $\hat{P}(0) = \hat{P}_0$ and $\hat{P}_0$ is symmetric and positive definite, exists for all $t \geq 0$, is continuously differentiable, bounded, symmetric, positive definite and there exist $\alpha_{\hat{P}_0, \Sigma} > 0$, which are independent of $\theta_0$, such that $\alpha_{\hat{P}_0, \Sigma} \leq \hat{P}(t) \leq \alpha_{\hat{P}_0, \Sigma}$ for any $t \geq 0$. Let $\hat{V} : (\hat{P}, \hat{\theta}) \rightarrow \hat{\theta}^T \hat{P} \hat{\theta}$. Let $t > 0$, in view of (9) and the definition of $\hat{P}(t)$, $\hat{V}(\hat{P}, \hat{\theta}) = -||\hat{\theta}||^2 - 2\gamma \hat{P}(t)\Upsilon^T(t)C(t)\Sigma(t)(C(t)\Upsilon(t))||\eta||^2.$

By following similar steps as above, we derive

\[
\hat{\dot{V}}(\hat{P}, \hat{\theta}) \leq -||\hat{\theta}||^2 + 2\gamma \alpha_{\hat{P}, \Sigma} ||\hat{\theta}|| ||\Upsilon|| ||\eta||, \tag{11}
\]

where $\alpha_{\hat{P}, \Sigma} > 0$ is a constant such that $||\Upsilon^T(t)C(t)\Sigma(t)|| \leq \alpha_{\hat{P}, \Sigma}$ for all $t \geq 0$, which exists since $\Sigma(t)$ and $C(t)$ are bounded.

Define $U : (P, \tilde{P}, \eta, \hat{\theta}) \rightarrow V(P, \eta) + \mu \hat{V}(\hat{P}, \hat{\theta})$ with $\mu > 0$ a constant, which will be selected below. In view of (10) and (11), for any $t \geq 0$,

\[
\dot{U}(P, \tilde{P}, \eta, \hat{\theta}) \leq -[1 - 2\gamma \alpha_{\hat{P}, \Sigma} ||\hat{\theta} - \theta_0|| ||\eta||^2]
+ 2\gamma \alpha_{\hat{P}, \Sigma} ||\eta|| ||\hat{\theta}|| ||\eta|| ||\theta - \theta_0|| - \mu ||\hat{\theta}||^2 + 2\gamma \alpha_{\hat{P}, \Sigma} ||\eta|| ||\hat{\theta}|| ||\eta|| = -\left[\left(||\eta||, ||\hat{\theta}||, M(||\eta||, ||\hat{\theta}||)\right)\right], \tag{12}
\]

where $M := \left(\begin{array}{cc} M_{11} & M_{12} \\ * & M_{22} \end{array}\right)$ with $M_{11} := 1 - 2\gamma \alpha_{\hat{P}, \Sigma} ||\hat{\theta} - \theta_0|| ||\eta||^2 - 2\gamma \alpha_{\hat{P}, \Sigma} ||\eta|| ||\hat{\theta}|| + \mu ||\hat{\theta}||^2 + 2\gamma \alpha_{\hat{P}, \Sigma} ||\eta|| ||\hat{\theta}|| ||\eta||$.

The first inequality above is ensured as long as $||\theta - \theta_0||$ is sufficiently small, in particular we assume that $||\theta - \theta_0|| < \frac{1}{4\gamma \alpha_{\hat{P}, \Sigma}}$ so that $1 - 2\gamma \alpha_{\hat{P}, \Sigma} ||\theta - \theta_0|| > \frac{1}{2}$. The second inequality also holds with $||\theta - \theta_0||$ sufficiently small, by taking $\mu < \frac{2\gamma \alpha_{\hat{P}, \Sigma} \nu(\Upsilon_0) ||\eta||^2}{1 - 2\gamma \alpha_{\hat{P}, \Sigma} ||\theta - \theta_0||}$; note that the denominator is well-defined since $\nu(\Upsilon_0) \geq 1$ in view of Claim 1. As a result, there exists $\delta_1 \in (0, \min\{\delta_1, \delta_2\})$, which is independent of $\theta_0$, such that $||\theta - \theta_0|| \leq \delta$ implies the existence of $\epsilon > 0$ such that, for $t \geq 0$, $U(P, \tilde{P}, P, \eta, \hat{\theta}) \leq ||\eta||^2.$

Since $\min\{\alpha_{\hat{P}, \Sigma}, \mu ||\hat{\theta}||^2\} \leq U(P, \tilde{P}, P, \eta, \hat{\theta}) \leq (\mu ||\hat{\theta}||^2)$ we deduce that $(\eta(t), \hat{\theta}(t))$ exponentially converges to 0 as $t \to \infty$. More precisely, there exist $c_1', c_2' > 0$, which depend on $\mathcal{X}, \mathcal{M}, \tilde{x}_0, \theta_0, \Upsilon_0$, such that $||\eta(t)||, ||\hat{\theta}(t)|| \leq c_1'e^{-c_2't}||\eta(0)||, ||\hat{\theta}(0)||$.

The Taylor expansion of each $a_{ij}$ with respect to $\theta$ gives $a_{ij}(t, \theta) = a_{ij}(t, 0) + \partial a_{ij}(t, \theta)|_{\theta = 0} \nu(t, \theta) + \rho_{ij}(t, \theta, \theta_0) \theta$, where $\rho_{ij}(t, \theta, \theta_0) = O(||\theta - \theta_0||^2)$. As a result,

\[
\dot{A}(t, \theta) = A(t, \theta) + \sum_{i=1}^{n_{a}} A_i(t, \theta_0) (\theta_i - \theta_0) + R(t, \theta, \theta_0), \tag{15}
\]

where $\theta = (\theta_1, \ldots, \theta_{n_{a}})$, $\theta_0 = (\theta_{0,1}, \ldots, \theta_{0,n_{a}})$, $\mathcal{X}(t, \theta_0) := \frac{\partial a_{ij}(t, \theta_0)}{\partial \theta_j}$ for $k \in \{1, \ldots, n_{\theta}\}$, $R(t, \theta, \theta_0) := \rho_{ij}(t, \theta, \theta_0)$. In view of (15), we modify the observer in (2) as

\[
\dot{\hat{x}}(t) = A(t, \theta_0) \hat{x}(t) + B(t, u(t) + \hat{\theta}(t, \theta_0, \sigma_X(\hat{x}(t))) \hat{\theta}(t)) + K(t, \theta_0) + \Upsilon^T(t)C(t)\Sigma(t) \Upsilon(t) \times (y(t) - C(t)\hat{x}(t))
\]

\[
\hat{\theta}(t) = \gamma \Upsilon^T(t)C(t)\Sigma(t)(y(t) - C(t)\hat{x}(t))
\]

\[
\hat{\theta}(t) = [A(t, \theta_0) - K(t, \theta_0) C(t)] \Upsilon(t) \times (\hat{x}(t), \sigma_X(\hat{x}(t))) \hat{\theta}(t) + \theta_0,
\]

where $\hat{X}(t, \theta_0, z) := \mathcal{X}(t, \theta_0) z \ldots \mathcal{X}_{n_{a}}(t, \theta_0, z)$ for $z \in \mathbb{R}^{n_x}$. The other matrices and parameters are selected as in (2).

**Proposition 1:** Consider systems (1) and (16). Suppose the following holds.

(i) Assumptions 2 and 3 hold.

(ii) Item (ii) of Theorem 1 holds along the solutions to (1) and (16).

\[
\rho_{ij}(t, \theta, \theta_0) = O(||\theta - \theta_0||^2) \text{ even though } \rho_{ij}
\]

depends on the time $t$, since $A(t, \theta)$ is assumed to be bounded with respect to the time, see Section II.
IV. ILLUSTRATIVE EXAMPLE

Consider the mass-spring system with two elements depicted in Figure 1 with masses $m_1 = 100$ and $m_2 = 100$, spring stiffness $k_1 = 5$, $k_2 = 10$ and $\theta > 0$ being the stiffness of the middle spring, which is assumed to be unknown, and $b_1 = 0.1$ and $b_2 = 0.4$ are the damping coefficients. The system is of the form of (1). Assumption 1 holds and Assumption 2 is also verified as $\theta = 0$. Taking $u(t) = 10 \sin(10t)$ for any $t \geq 0$, Assumption 3 is satisfied since the infinity norm of the input is bounded and $A$ is Hurwitz. We have designed the adaptive observer as in (2) with $\gamma = 10^3$, $\Sigma(t) = 10^3 I$ and $K$ such that the eigenvalues of $A - KC$ are $(-1, -1.5, -2, -2.5)$. We have run simulations with $\theta = 15$, and different values of $\theta_0$, $x(0)$, $\dot{x}(0)$, $\theta(0)$ and $\dot{\theta}(0)$ were considered. Simulations suggest that the convergence of the adaptive observer is independent of the initial conditions of $x$, $\dot{x}$, $\theta$ and $T$: only $\theta_0$ seems to matter. Also, the asymptotic convergence of the estimation errors is seen whenever $\theta_0 \in [\theta - 11, \theta + 75]$, which means that $\theta_0$ does not need to be very “close” to $\theta$ for the observer to work for this example.

V. CONCLUSION

We presented an adaptive observer for linear time-varying system whose state matrix $A(t, \theta)$ depends on unknown parameters. When $A(t, \theta)$ is affine in $\theta$, the proposed scheme ensures the exponential convergence of the estimates to the true values provided some initial guess of the unknown parameter is sufficiently closed to the latter and a persistence of excitation holds. When $A(t, \theta)$ is only smooth in $\theta$, a modified version of the observer has been proposed, which ensures the approximate convergence to zero of the estimation errors.
