HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
COLORING THE RATIONALS IN REVERSE MATHEMATICS

EMANUELE FRITTAION AND LUDOVIC PATEY

Abstract. Ramsey’s theorem for pairs asserts that every 2-coloring of the pairs of integers has an infinite monochromatic subset. In this paper, we study a strengthening of Ramsey’s theorem for pairs due to Erdős and Rado, which states that every 2-coloring of the pairs of rationals has either an infinite 0-homogeneous set or a 1-homogeneous set of order type \( \eta \), where \( \eta \) is the order type of the rationals. This theorem is a natural candidate to lie strictly between the arithmetic comprehension axiom and Ramsey’s theorem for pairs. This Erdős-Rado theorem, like the tree theorem for pairs, belongs to a family of Ramsey-type statements whose logical strength remains a challenge.

1. Introduction

In this paper, we investigate the reverse mathematics of a well-known theorem due to Erdős and Rado about 2-colorings of pairs of rationals. This theorem is a natural strengthening of Ramsey’s theorem for pairs and two colors. We say that an order type \( \alpha \) is Ramsey, and write \( \alpha \to (\alpha)\)2, if for every coloring \( f: [L]^2 \to 2 \), where \( L \) is a linear order of order type \( \alpha \), there is a homogeneous set \( H \) such that \( (H, \leq_{L}) \) has order type \( \alpha \). Ramsey’s theorem for pairs and two colors asserts that \( \omega \) is Ramsey. It turns out that \( \omega \) and \( \omega^{*} \) are the only countable Ramsey order types. In particular, \( \eta \to (\eta)^{2}_{\geq} \) does not hold, where \( \eta \) is the order type of the rationals. A standard counterexample is as follows. Fix a one-to-one map \( i: \mathbb{Q} \to \mathbb{N} \). Define \( f: [\mathbb{Q}]^2 \to 2 \) by letting

\[
f(x, y) = \begin{cases} 
0 & \text{if } x <_{\mathbb{Q}} y \land i(x) < i(y); \\
1 & \text{if } x <_{\mathbb{Q}} y \land i(x) > i(y). 
\end{cases}
\]

A homogeneous set of order type \( \eta \) would give an embedding of \( \mathbb{Q} \) into \( \omega \) (with color 0) or \( \omega^{*} \) (with color 1), which is impossible. Even though Ramsey’s theorem for rationals fails, Erdős and Rado [6, Theorem 4, p. 427] proved the following Ramsey-type theorem (see also Rosenstein [17, Theorem 11.7, p. 207]).

**Theorem 1.1** (Erdős-Rado theorem) The partition relation \( \eta \to (\eta, \eta)^{2} \) holds.

The relation \( \eta \to (\eta, \eta)^{2} \) asserts that for every coloring \( f: [L]^2 \to 2 \), where \( L \) is a linear order of order type \( \eta \), there is either an infinite 0-homogeneous set or a 1-homogeneous set \( H \) such that \( (H, \leq_{L}) \) has order type \( \eta \).

We study Theorem 1.1 within the framework of reverse mathematics (see Simpson [21]). Reverse mathematics is a vast mathematical program whose goal is to study the logical strength of ordinary theorems in terms of set existence axioms. It uses the framework of subsystems of second-order arithmetic, with the base theory \( \text{RCA}_{0} \) (recursive comprehension axiom). \( \text{RCA}_{0} \) is composed of \( P^{-} \), that is, the basic first-order Peano axioms for \( 0, 1, +, \times, < \), together with \( \Delta_{1}^{0}-\text{comprehension} \) and \( \Sigma_{1}^{0}-\text{induction} \) with number and set parameters. \( \text{RCA}_{0} \) is usually thought of as capturing computable mathematics. It turns out that the large majority of countable mathematics can be proven in \( \text{ACA}_{0} \), where \( \text{ACA}_{0} \) is \( \text{RCA}_{0} \) together with arithmetic comprehension. See Hirschfeldt [8] for a gentle presentation of the reverse mathematics below \( \text{ACA}_{0} \).

We formalize Theorem 1.1 in \( \text{RCA}_{0} \) as follows.

\( \text{ER}_2^2 \) For every coloring \( f : [\mathbb{Q}]^2 \to 2 \) there exists either an infinite 0-homogeneous set or a
1-homogeneous set \( H \) such that \( \langle H, \leq \rangle \) is dense.

Here \( \mathbb{Q} \) is any fixed primitive recursive presentation of the rationals. We may safely assume that
the domain of \( \mathbb{Q} \) is \( \mathbb{N} \). Note that provably in \( \text{RCA}_0 \) every two (countable) linear orders
of order type \( \eta \) are isomorphic and any dense linear order obviously contains a linear order of
order type \( \eta \). Therefore \( \text{ER}_2^2 \) is provably equivalent over \( \text{RCA}_0 \) to the statement of Theorem 1.1.

In order to study \( \text{ER}_2^2 \) we also consider a version of the infinite pigeonhole principle over
the rationals, namely the statement:

\( \text{ER}^1 \) For every \( n \) and for every \( n \)-coloring \( f : \mathbb{Q} \to n \) there exists a dense homogeneous set.

The early study of reverse mathematics has led to the observation that most of the theorems
happen to be equivalent to five main subsystems of second-order arithmetic that Montalbán [13]
called the “Big Five”. However, Ramsey’s theory provides many statements escaping this
observation. Perhaps the most well-known example is Ramsey’s theorem for pairs and two
colors (\( \text{RT}_2^2 \)). The effective analysis of Ramsey’s theorem was started by Jockusch [10]. In
the framework of reverse mathematics, Simpson (see [21]), building on Jockusch results, proved that
whenever \( n \geq 3 \) and \( k \geq 2 \), \( \text{RT}_k^n \) is equivalent to \( \text{ACA}_0 \) over \( \text{RCA}_0 \). The case of \( \text{RT}_2^2 \) had been a
long-standing open problem until Seetapun [19] proved that \( \text{RT}_2^2 \) is strictly weaker than \( \text{ACA}_0 \)
over \( \text{RCA}_0 \). Cholak, Jockusch and Slaman [1] paved the way to the reverse mathematics analysis
of Ramsey’s theorem for pairs. Since then, many consequences of Ramsey’s theorem for pairs
have been studied, leading to a whole zoo of independent statements. However, no natural
statement besides Ramsey’s theorem for pairs (\( \text{RT}_2^2 \)) is known to be strictly between \( \text{ACA}_0 \)
and \( \text{RT}_2^2 \) over \( \text{RCA}_0 \). The only known candidate is the tree theorem for pairs (\( \text{TT}_2^2 \)) studied
in [2, 3, 5, 15]. We show that \( \text{ER}_2^2 \) also lies between \( \text{ACA}_0 \) and \( \text{RT}_2^2 \), and so represents another
candidate, arguably more natural than \( \text{TT}_2^2 \).

Although no relation is known between them, \( \text{TT}_2^2 \) and \( \text{ER}_2^2 \) share some essential combinatorial
features and put the emphasis on a new family of Ramsey-type theorems, characterized by what
we call a disjoint extension commitment. See section 5 for a discussion on this notion. Some
separations known for variants of \( \text{TT}_2^2 \) are essentially due to this common feature, which enables
us to prove the same separations for variants of \( \text{ER}_2^2 \). In particular, we prove that \( \text{ER}_2^2 \) does not
computably reduce to Ramsey’s theorem for pairs with an arbitrary number of colors (\( \text{RT}_2^2 \)).
However, we cannot simply adapt this “one-step separation” to a separation over \( \omega \)-models,
and in particular over \( \text{RCA}_0 \), as in the case of \( \text{TT}_2^2 \) [15]. This is the first known example of such
an inability. Indeed, a diagonalization against an \( \text{RT}_2^2 \)-instance is similar to a diagonalization
against two \( \text{RT}_2^2 \)-instances. Therefore, diagonalizing against \( \text{RT}_2^2 \) has some common flavor with
a separation over standard models.

Among the consequences of Ramsey’s theorem for pairs, Ramsey’s theorem for singletons
(\( \text{RT}^1 \)), also known as the infinite pigeonhole principle, is of particular interest. \( \text{RT}^1 \) happens
to be equivalent to the \( \Sigma_2^b \) bounding scheme (see Hirst [9]). The \( \Sigma_2^b \) bounding scheme (\( \text{B}_2 \))
is formally defined as

\[
(\forall x < a)\exists y \varphi(x, y, a) \implies \exists b(\forall x < a)(\exists y < b)\varphi(x, y, n)
\]

where \( \varphi \) is any \( \Sigma_2^b \) formula. One may think of \( \text{B}_2 \) as asserting that the finite union of finite
sets is finite (see for instance [7]). We show that \( \text{ER}^1 \), the corresponding pigeonhole principle
for rationals, is strictly stronger than \( \text{B}_2 \), and hence has the same reverse mathematics status
as the tree theorem for singletons (\( \text{TT}^1 \)) [3].

For the purpose of separating \( \text{ER}_2^2 \) from \( \text{RT}^2 \) over computable reducibility, we also introduce
the asymmetric version of \( \text{ER}^1 \) for two colors, namely \( \text{a-ER}^1_2 \), stating that for every partition
\( A_0 \cup A_1 = \mathbb{Q} \) of the rationals there exists either an infinite subset of \( A_0 \) or a dense subset of \( A_1 \).
Indeed, we show the existence of a \( \Delta_0^b \)-instance of \( \text{a-ER}^1_2 \), and hence of a computable instance
of \( \text{ER}_2^2 \), which does not reduce to any computable instance of \( \text{RT}^2 \).
1.1. Definitions and notation

String. A string is an ordered tuple of bits $b_0, \ldots, b_{n-1}$, that is, such that $b_i < 2$ for every $i < n$. The empty string is written $\langle \rangle$. A real is an infinite listing of bits $b_0, b_1, \ldots$. Given $s \in \omega$, $2^s$ is the set of strings of length $s$ and $2^{<s}$ is the set of strings of length $< s$. Similarly, $2^{\omega}$ is the set of finite strings and $2^\omega$ is the set of reals. Given a string $\sigma \in 2^\omega$, we denote by $|\sigma|$ its length. Given two strings $\omega$, the set of finite strings and $2$, $2^\omega$ is a set of finitely many elements. Given a real $X$, we write $\sigma \prec X$ if $\sigma = X|n$ for some $n \in \omega$, where $X|n$ denotes the restriction of $X$ to its first $n$ elements. We may identify a real with a set of integers by considering that the real is its characteristic function.

Tree, path. A binary tree $T \subseteq 2^{<\omega}$ is a set downward-closed under the prefix relation. A real $P$ is a path though $T$ if for every $\sigma \prec P$, $\sigma \in T$.

Sets, partitions. Given two sets $A$ and $B$, we denote by $A \subseteq B$ the formula $(\forall x \in A)(\forall y \in B)[x < y]$ and by $A \subseteq^* B$ the formula $(\forall^\infty x \in A)[x \in B]$, meaning that $A$ is included in $B$ up to finitely many elements. Given a set $X$ and some integer $k$, a $k$-partition of $X$ is a $k$-uple of pairwise disjoint sets $A_0, \ldots, A_{k-1}$ such that $A_0 \cup \cdots \cup A_{k-1} = X$. A Mathias condition is a pair $(F, X)$ where $F$ is a finite set, $X$ is an infinite set and $F < X$. A condition $(F_1, X_1)$ extends $(F, X)$ (written $(F_1, X_1) \leq (F, X)$) if $F \subseteq F_1$, $X_1 \subseteq X$ and $F_1 \setminus F \subseteq X$. A set $G$ satisfies a Mathias condition $(F, X)$ if $F \subseteq G$ and $G \setminus F \subseteq X$.

2. The Erdős-Rado theorem in reverse mathematics

We start off the analysis of the Erdős-Rado theorem by proving that the statement $\text{ER}_2^2$ lies between $\text{ACA}_0$ and $\text{RT}_2^2$. On the lower bound hand, $\text{ER}_2^2$ can be seen as an immediate strengthening of $\text{RT}_2^2$. The upper bound is an effectivization of the original proof of $\text{ER}_2^2$ by Erdős and Rado in [6].

Lemma 2.1 (RCA$_0$) $\text{ER}_2^2 \rightarrow \text{RT}_2^2$.

Proof. An instance of $\text{RT}_2^2$ can be regarded as an instance of $\text{ER}_2^2$. Moreover, provably in RCA$_0$, a dense set is infinite. \hspace{2cm} \Box

The rest of this section is devoted to show that $\text{ER}_2^2$ is provable in ACA$_0$. For this purpose, we give the following definition.

Definition 2.2 (RCA$_0$) By interval we mean a set of the form $I = [x, y] \subseteq \mathbb{Q}$ for $x, y \in \mathbb{Q}$. We say that $A \subseteq \mathbb{Q}$ is somewhere dense if $A$ is dense in some interval of $\mathbb{Q}$, i.e., there exists an interval $I$ such that for all intervals $J \subseteq I$ we have that $A \cap J \neq \emptyset$. We call $A$ nowhere dense otherwise.

Notice that the above notion of nowhere dense is the usual topological notion with respect to the order topology of $\mathbb{Q}$. In general, the nowhere dense sets of a topological space form an ideal. This is crucial in the proof by Erdős and Rado. For this reason, we also use the terminology positive and small for somewhere dense and nowhere dense respectively. In RCA$_0$ we can show that nowhere dense subsets of $\mathbb{Q}$ are small, meaning that:

1. If $A \subseteq \mathbb{Q}$ is small and $B \subseteq A$, then $B$ is small;
2. If $A, B \subseteq \mathbb{Q}$ are small, then $A \cup B$ is small.

With enough induction, it is possible to generalize (2) to finitely many sets.

Lemma 2.3 (RCA$_0$ + $\Sigma^0_2$) If $A_i$ is a small subset of $\mathbb{Q}$ for all $i < n$, then $\bigcup_{i<n} A_i$ is small.

Proof. Suppose that $A_i$ is small for every $i < n$. Fix an interval $I$. We aim to show that $A^n = \bigcup_{i<n} A_i$ is not dense in $I$. By $\Sigma^0_2$-induction we prove that for all $i \leq n$ there exists an interval $J \subseteq I$ such that $A^i \cap J = \emptyset$, where $A^i = \bigcup_{j<i} A_j$. For $i = n$ we have the desired conclusion. The case $i = 0$ is trivial. Suppose $i + 1 \leq n$. By induction there exists an interval
Define Blue(A) an infinite 0-homogeneous set. We define by arithmetical recursion a sequence (x_i)_{i \in \mathbb{N}} as follows. Suppose we have defined x_i for all i < n, and assume by arithmetical induction that A_n = \bigcap_{i<n} Red(x_i) is positive, and hence red-admissible (where \bigcap_{i<0} Red(x_i) = \emptyset). Search for the \omega-least x_n \in A_n such that A_n \cap Red(x_n) = \bigcap_{i<n+1} Red(x_i) is positive. By definition, the set \{x_n; n \in \mathbb{N}\} is infinite and 0-homogeneous.

Case II. There is a positive subset A of Q which is not red-admissible. In this case, we show that there exists a dense 1-homogeneous set. Let I be a witness of A being positive. Fix an enumeration (I_n)_{n \in \mathbb{N}} of all subintervals of I. Notice that by definition A intersects every I_n.

We define by arithmetical recursion a sequence (x_n)_{n \in \mathbb{N}} as follows. Let x_0 \in A \cap I_0. Suppose we have defined x_i \in A \cap I_i for all i < n. By Lemma 2.3, since every A \cap Red(x_i) with i < n is small, it follows that E = \bigcup_{i<n} (A \cap Red(x_i)) is small. Let J \subseteq I_n be such that E \cap J = \emptyset. We may safely assume that no x_i with i < n belongs to J. Since A is dense in I and J \subseteq I, we can find x_n \in A \cap J. In particular, x_n \in \bigcap_{i<n} Blue(x_i). Therefore \{x_n; n \in \mathbb{N}\} is dense and 1-homogeneous.

Remark 2.5 A similar proof shows that RT^2_2 is provable in ACA_0. In fact, we can consider the ideal of finite sets of \mathbb{N} so that a positive set is just an infinite set and a red-admissible set is a set A \subseteq \mathbb{N} such that A \cap Red(x) is infinite for some x \in A.

3. Pigeonhole principle on Q

We next consider the statement ER^1 asserting that every finite coloring of rationals has a dense homogeneous set. The main result is that ER^1 is stronger than BSigma^0_2 over RCA_0. We achieve this by adapting the model-theoretic proof of Corduan, Groszek, and Mileti [3] that separates TT^1_1 from BSigma^0_2. Basically, in a model of RCA_0 + \neg ISigma^0_2, there are a real X and an X-recursive instance of ER^1 with no X-recursive solutions. Before going into the details of this proof, we establish the following simple reverse mathematics facts.

Lemma 3.1 Over RCA_0,
1) ER^2_2 \lor ISigma^0_2 \rightarrow ER^1
2) ER^1 \rightarrow RT^1.

Proof. 1) Let f: Q \rightarrow n be a given coloring. First assume ER^2_2, and let g: [Q]^2 \rightarrow 2 be defined by g(x, y) = 1 if and only if f(x) = f(y). Provably in RCA_0 every one-to-one function from an infinite set is unbounded. Then by ER^2_2 there exists a dense 1-homogeneous set for g, which is homogeneous for f.

Now assume BSigma^0_2 and define A_i = f^{-1}(i) for i < n. As Q = \bigcup_{i<n} A_i is positive, by lemma 2.3, there exists i < n such that A_i is positive. From A_i we can compute a dense i-homogeneous set.

2) is trivial. □

As in [3], the proof of our separation result consists of a few lemmas. We start by first adapting [3, Lemma 3.4] (see Lemma 3.3 below). The combinatorial core of the proof is based on the following.

Lemma 3.2 (ISigma^1_1) For each e < n, let \Gamma_e consist of 4n pairwise disjoint intervals of Q. Then there exist 2n pairwise disjoint intervals (I_{e,i}; e < n, i < 2) such that I_{e,i} \in \Gamma_e for all e < n and i < 2.
Proof. Let $\Gamma_e, e < n$, be given. Consider the following recursive procedure. At each stage we define $\Gamma_{e,s}$ for $e < n$ and $s$, as follows. At stage 0, $\Gamma_{e,0} = \Gamma_e$ and $\Delta_0 = \emptyset$. At stage $s + 1$, if $|\Delta_s| = 2n$ or $\Gamma^s = \bigcup_{e < n} \Gamma_{e,s}$ is empty, we are done. Otherwise search for $I \in \Gamma^s$ minimal with respect to inclusion (such an interval exists by $\Sigma_1$). Add $I$ to $\Delta_s$, that is, $\Delta_{s+1} = \Delta_s \cup I$. Let $e$ be such that $I \in \Gamma_{e,s}$. If $\Delta_s$ already contains an interval in $\Gamma_e$, let $\Gamma_{e,s+1} = \emptyset$, otherwise let $\Gamma_{e,s+1} = \Gamma_{e,s} \setminus \{I\}$. For all $j \neq e$, let $\Gamma_{j,s+1} = \{J \in \Gamma_{j,s} : I \cap J = \emptyset\}$. Notice that by the choice of $I$ as minimal, at most two intervals from each $\Gamma_{j,s}$ with $j \neq e$ have nonempty intersection with $J$.

By $\Sigma_1$ (indeed $\Sigma_0$) it is easy to show that, for all $s < 2n + 1$, $\Delta_s$ consists of $s$ disjoint intervals from $\bigcup_{e < n} \Gamma_e$ with at most two intervals from the same $\Gamma_e$, that every interval in $\Delta_s$ is disjoint from any interval in $\Gamma^s$, and that if $\Delta_s$ does not contain 2 intervals from $\Gamma_e$, then $\Gamma_{e,s}$ contains at least $4n - 2s$ intervals. In particular, $\Delta_{2n}$ is as desired. \hfill $\square$

Lemma 3.3 (RCA$_0$) For every real $X$ there exists an $X$-recursive function $d : \mathbb{N} \times \mathbb{Q} \to 2$ such that for all $n$ and $e < n$, if $W^X_e$ is a dense set of $\mathbb{Q}$, then there exist two disjoint intervals $I_{0}, I_{1}$ such that $W^X_e \cap I_{i}$ is infinite for all $i < 2$ and $d(n, x) = i$ for all $i < 2$ and for almost every $x \in I_{i}$.

Proof sketch. Our strategy to defeat $n$-many dense sets $\{A_{e} : e < n\}$ is to choose 2$n$ pairwise disjoint intervals $I_{0,e}, I_{1,e}$ for $e < n$ so that each $I_{e,i}$ has end-points in $A_{e}$, and assign color $i$ to the interval $I_{e,i}$ for all $e < n$ and $i < 2$. As we want to diagonalize against $n$-many potential dense sets of the form $W^X_e$ for $e < n$ and we cannot decide uniformly in $n$ which ones are dense, we act only when some $W^X_e$ outputs $4n + 1$ points. We then specify a set $\Gamma_e$ of $4n$ disjoint intervals with end-points in $W^X_e$ and from each $\Gamma_e$ currently defined we choose intervals $I_{0,e}$ and $I_{1,e}$ as in Lemma 3.2. Every time we act, our choice of $I_{0,e}$ and $I_{1,e}$ might change, but this happens at most $n$-many times. As the actual construction is essentially the one in the proof of [3, Lemma 3.4], we leave the details to the reader. \hfill $\square$

The next lemma is the key part of the whole argument (see [3, Proposition 3.5]).

Lemma 3.4 Let $M$ be a model of RCA$_0 + \Sigma^0_2$. Then for some real $X \in M$ there is an $X$-recursive (in the sense of $M$) coloring $f$ of $\mathbb{Q}$ into $M$-finitely many colors such that no $X$-recursive dense set is homogeneous for $f$.

Proof. Let $X \in M$ witness the failure of $\Sigma^0_2$. Then there exists an $X$-recursive function $h : \mathbb{N} \to \mathbb{N}$ such that for some number $a$, the range of the partial function $h(y) = \lim_{s \to \infty} h(y,s)$ is unbounded on $\{y : y < a\}$ (see also [3, Lemma 3.6]). Define $f : \mathbb{Q} \to 2^a$ by $f(x) = \langle d(h(y,x), x) : y < a \rangle$, where $d(n, x)$ is the function of Lemma 3.3. Let $W^X_e$ be a dense set of $\mathbb{Q}$. We aim to show that $W^X_e$ is not homogeneous for $f$. Let $y < a$ such that $h(y) > e$. Observe that for almost every $x \in \mathbb{Q}$ the $y$th bit of $f(x)$ is $d(h(y), x)$. As $e < h(y)$, let $I_0$ and $I_1$ be two intervals as in Lemma 3.3. Now for sufficiently large $x_0 \in W^X_e \cap I_0$ and $x_1 \in W^X_e \cap I_1$ we have $d(h(y, x_i), x_i) = d(h(y), x_i) = i$, and hence $f(x_0) \neq f(x_1)$. \hfill $\square$

We can finally prove the analogue of [3, Corollary 3.8], which is the main result.

Theorem 3.5 Let $P$ be a $\Pi^1_1$ sentence. Then RCA$_0 + P \vdash \text{ER}^1$ if and only if RCA$_0 + P \vdash \Sigma^0_2$. In particular, RCA$_0 + \Sigma^0_2 \not\vdash \text{ER}^1$.

Proof. The argument is the same as in the proof of [3, Theorem 3.7]. As RCA$_0 + \Sigma^0_2 \not\vdash \text{ER}^1$, we just need to prove one implication. Suppose that RCA$_0 + P \not\vdash \Sigma^0_2$, and let $M$ be a model of RCA$_0 + P$ where $\Sigma^0_2$ fails. By Lemma 3.4, for some real $X \in M$, there exists an $X$-recursive instance of $\text{ER}^1$ with no $X$-recursive solutions. Let $M'$ be the submodel of $M$ with the same first-order part as $M$ and second-order part consisting of the reals recursive in $X$ (in the sense of $M$). Therefore $\text{ER}^1$ fails in $M'$. Since $M'$ has same first-order part as $M$, $M'$ satisfies the $\Pi^1_1$
sentence $P$. As the reals of $M'$ are the ones recursive in a given real of $M$, $M$ satisfies RCA$_0$. Thus $\text{RCA}_0 + P \not\vdash \text{ER}^1$.

4. ER$_2^2$Does Not Computably Reduce to RT$_2^2$

Many proofs of $Q \rightarrow P$ over RCA$_0$ make use only of one $Q$-instance to solve a $P$-instance. This is the notion of computable reducibility.

**Definition 4.1** (Computable reducibility) Fix two $\Pi^1_1$ statements $P$ and $Q$. $P$ is computably reducible to $Q$ (written $P \leq_c Q$) if every $P$-instance $X_0$ computes a $Q$-instance $X_1$ such that for every solution $Y$ to $X_1$, $Y \oplus X_0$ computes a solution to $X_0$.

Proving that $P \leq_c Q$ is not sufficient to deduce that $\text{RCA}_0 \vdash Q \rightarrow P$. One needs to prove that this reducibility can be formalized within RCA$_0$, and in particular that $\Sigma^0_1$-induction is sufficient to prove its validity. The fine-grained nature of computable reducibility enables one to exhibit distinctions between statements which would not have been revealed in reverse mathematics. For example, RT$_2^2$ and RT$_2^{k+1}$ are equivalent over RCA$_0$ whereas RT$_2^2 \not\leq_c$ RT$_2^k$ [16].

This notion of reducibility can be also seen as an intermediary step to tackle difficult separations [4]. Proving that $P \not\leq_c Q$ is simpler than separating $Q$ from $P$ over $\omega$-models. Lerman, Solomon and Towsner [12] introduced a framework to separate Ramsey-type statements over $\omega$-models, in which they transform a one-step diagonalization, that is, computable non-reducibility, into a separation in the sense of reverse mathematics. In this section, we prove that the Erdős-Rado theorem for pairs does not reduce to Ramsey’s theorem for pairs in one step.

**Theorem 4.2** ER$_2^2 \not\leq_c$ RT$_2^2$.

Interestingly, this diagonalization does not seem to be easily generalizable to a separation over $\omega$-models. A reason is that the fairness property ensured by the ER$_2^2$-instance does not seem to be preserved by weak König’s lemma. This is hitherto the first example of a computable non-reducibility of a principle $P$ to RT$_2^2$ which is not generalizable to a proof that RT$_2^2$ does not imply $P$ over RCA$_0$.

The remainder of this section is devoted to a proof of Theorem 4.2. The notion of fairness presented below may have some ad-hoc flavor. It has been obtained by applying the main ideas of the framework of Lerman, Solomon and Towsner [12, 14]. Thanks to an analysis of the combinatorics of Ramsey’s theorem for pairs and the Erdős-Rado theorem for pairs, we prove our computable non-reducibility result by constructing an instance of ER$_2^2$ ensuring the density of the diagonalizing conditions in the forcing notion of RT$_2^2$. Then we abstract the diagonalization to any $\Sigma^0_1$ formula, to get rid of the specificities of the forcing notion of RT$_2^2$ in the notion of fairness preservation. See [15] for a detailed example of the various steps of this framework, leading to a separation of RT$_2^2$ from the tree theorem for pairs over RCA$_0$.

**Definition 4.3** (Simple partition) A simple partition $\text{int}_Q(S)$ is a finite sequence of open intervals $(-\infty, x_0), (x_0, x_1), \ldots, (x_{n-1}, +\infty)$ for some set of rationals $S = \{x_0 <_Q \cdots <_Q x_{n-1}\}$. We set $\text{int}_Q(\emptyset) = \{Q\}$. A simple partition $I_0, \ldots, I_{n-1}$ refines another simple partition $J_0, \ldots, J_{m-1}$ if for every $i < n$, there is some $j < m$ such that $I_i \subseteq J_j$. Given two simple partitions $I_0, \ldots, I_{n-1}$ and $J_0, \ldots, J_{m-1}$, the product $\bar{I} \otimes \bar{J}$ is the simple partition

$$\{I \cap J : I \in \bar{I} \land J \in \bar{J}\}$$

One can easily see that $\text{int}_Q(S)$ refines $\text{int}_Q(T)$ if $T \subseteq S$ and that $\text{int}_Q(S \cup T) = \text{int}_Q(S) \otimes \text{int}_Q(T)$. Note that every simple partition has a finite description, since the set $S$ and each rational has a finite description. Also note that a simple partition is not a true partition of $Q$ since the endpoints do not belong to any interval. However, we have $S \cup \bigcup \text{int}_Q(S) = Q$. 

Definition 4.4 (Matrix) An $m$-by-$n$ matrix $M$ is a rectangular array of rationals $x_{i,j} \in \mathbb{Q}$ such that $x_{i,j} < q x_{i,k}$ for each $i < m$ and $j < k < n$. The $i$th row $M(i)$ of the matrix $M$ is the $n$-tuple of rationals $x_{i,0} < \cdots < x_{i,n-1}$. The simple partition $\text{int}_Q(M)$ is defined by $\bigotimes_{i<m} \text{int}_Q(M(i))$. In particular, $\bigotimes_{i<m} \text{int}_Q(M(i))$ refines the simple partition $\text{int}_Q(M(i))$ for each $i < m$.

It is important to notice that an $m$-by-$n$ matrix is formally a 3-tuple $\langle m, n, M \rangle$ and not only the matrix itself $M$. This distinction becomes important when dealing with the degenerate cases. An $m$-by-$0$ matrix $M$ and a $0$-by-$n$ matrix $N$ are both empty. However, they have different sizes. In particular, we shall define the notion of $M$-type for a matrix, and this definition will depend on the number of columns of the matrix $M$, which is $0$ for $M$, and $n$ for $N$. Notice also that, for a degenerate matrix $M$, the simple partition $\text{int}_Q(M)$ is the singleton $\{Q\}$.

Given a simple partition $\vec{I}$, we want to classify the $k$-tuples of rationals according to which interval of $\vec{I}$ they belong to. This leads to the notion of $(\vec{I}, k)$-type.

Definition 4.5 (Type) Given a simple partition $I_0, \ldots, I_{n-1}$ and some $k \in \omega$, an $(\vec{I}, k)$-type is a tuple $T_0, \ldots, T_{k-1}$ such that $T_i \in \vec{I}$ for each $i < k$. Given an $m$-by-$n$ matrix $M$, an $M$-type is an $(\text{int}_Q(M), n)$-type.

We now state two simple combinatorial lemmas which will be useful later. The first trivial lemma simply states that each $m$-tuple of rationals (different from the endpoints of a simple partition) belongs to a type.

Lemma 4.6 For every simple partition $I_0, \ldots, I_{n-1}$ and every $k$-tuple of rationals $x_0, \ldots, x_{k-1} \in \bigcup_{i<n} I_i$, there is an $(\vec{I}, k)$-type $T_0, \ldots, T_{k-1}$ such that $x_j \in T_j$ for each $j < k$.

Proof. Fix $k$ rationals $x_0, \ldots, x_{k-1}$. For each $i < k$, there is some interval $T_i \in \vec{I}$ such that $x_i \in T_i$ since $x_i \in \bigcup_{j<n} I_j$. The sequence $T_0, \ldots, T_{k-1}$ is the desired $(\vec{I}, k)$-type. \hfill \Box

The next lemma is a consequence of the pigeonhole principle.

Lemma 4.7 For every $m$-by-$n$ matrix $M$ and every $M$-type $T_0, \ldots, T_{n-1}$, there is an $m$-tuple of intervals $J_0, \ldots, J_{m-1}$ with $J_i \in \text{int}_Q(M(i))$ such that

$$\bigcup_{j<n} T_j \cap \bigcup_{i<m} J_i = \emptyset$$

Proof. Let $T_0, \ldots, T_{n-1}$ be an $M$-type. For every $i < m$ and $j < n$, there is some $J \in \text{int}_Q(M(i))$ such that $T_j \subseteq J$. Since $|\text{int}_Q(M(i))| = n + 1$, there is an interval $J_i \in \text{int}_Q(M(i))$ such that $\bigcup_{j<n} T_j \cap J_i = \emptyset$. \hfill \Box

Definition 4.8 (Formula, valuation) Given an $m$-by-$n$ matrix $M$, an $M$-formula $\varphi(\vec{U}, \vec{V})$ with distinguished (finite coded) set variables $U_j$ for each $j < n$ and $V_{i,I}$ for each $i < m$ and $I \in \text{int}_Q(M(i))$. An $M$-valuation $(\vec{R}, \vec{S})$ is a tuple of finite sets $R_j \subseteq \mathbb{Q}$ for each $j < n$ and $S_{i,I} \subseteq I$ for each $i < m$ and $I \in \text{int}_Q(M(i))$. The $M$-valuation $(\vec{R}, \vec{S})$ is of type $\vec{T}$ for some $M$-type $T_0, \ldots, T_{n-1}$ if moreover $R_j \subseteq T_j$ for each $j < n$. The $M$-valuation $(\vec{R}, \vec{S})$ satisfies $\varphi$ if $\varphi(\vec{R}, \vec{S})$ holds.

Given some valuation $(\vec{R}, \vec{S})$ and some integer $s$, we write $(\vec{R}, \vec{S}) > s$ to say that for every $x \in (\bigcup \vec{R}) \cup (\bigcup \vec{S})$, $x > s$. Following the terminology of [12], we define the notion of essentiality for a formula (an abstract requirement), which corresponds to the idea that there is room for diagonalization since the formula is satisfied by valuations which are arbitrarily far.

Definition 4.9 (Essential formula) Given an $m$-by-$n$ matrix $M$, an $M$-formula $\varphi$ is essential if for every $s \in \omega$, there are an $M$-type $\vec{T}$ and an $M$-valuation $(\vec{R}, \vec{S}) > s$ of type $\vec{T}$ such that $\varphi(\vec{R}, \vec{S})$ holds.
The notion of fairness is defined accordingly. If some formula is essential, that is, leaves enough room for diagonalization, then there is an actual valuation which will diagonalize against the $\mathsf{ER}_2^0$-instance.

**Definition 4.10** (Fairness) Fix two sets $A_0, A_1 \subseteq \mathbb{Q}$. Given an $m$-by-$n$ matrix $M$, an $M$-valuation $(\vec{R}, \vec{S})$ diagonalizes against $A_0, A_1$ if $\vec{R} \subseteq A_1$ and for every $i < m$, there is some $I \in \int_{\mathbb{Q}}(M(i))$ such that $S_{i,I} \subseteq A_0$. A set $X$ is fair for $A_0, A_1$ if for every $m, n \in \omega$, every $m$-by-$n$ matrix $M$ and every $\Sigma_1^0 X$ essential $M$-formula, there is an $M$-valuation $(\vec{R}, \vec{S})$ diagonalizing against $A_0, A_1$ such that $\varphi(\vec{R}, \vec{S})$ holds.

Of course, if $Y \leq_T X$, then every $\Sigma_1^0 Y$ formula is $\Sigma_1^0 X$. As an immediate consequence, if $X$ is fair for some $A_0, A_1$ and $Y \leq_T X$, then $Y$ is fair for $A_0, A_1$.

Now that we have introduced the necessary terminology, we create a non-effective instance of $\mathsf{a-ER}_2^0$ which will serve as a bootstrap for fairness preservation. Remember that $\mathsf{eps}$ asserts that for every partition $A_0 \cup A_1 = \mathbb{Q}$ of the rationals there exists either an infinite subset of $A_0$ or a dense subset of $A_1$.

**Lemma 4.11** For every set $C$, there exists a $\Delta_2^0 C$ partition $A_0 \cup A_1 = \mathbb{Q}$ such that $C$ is fair for $A_0, A_1$.

**Proof.** The proof is a no-injury priority construction. Let $M_0, M_1, \ldots$ be an enumeration of all $m$-by-$n$ matrices and $\varphi_0, \varphi_1, \ldots$ be an effective enumeration of all $\Sigma_1^0 C M_k$-formulas for every $m, n \in \omega$. We want to satisfy the following requirements for each pair of integers $e, k$.

- $\mathcal{R}_{e,k}$: If the $M_k$-formula $\varphi_e$ is essential, then $\varphi_e(\vec{R}, \vec{S})$ holds for some $M_k$-valuation $(\vec{R}, \vec{S})$ diagonalizing against $A_0, A_1$.

The requirements are ordered via the standard pairing function $\langle \cdot, \cdot \rangle$. The sets $A_0$ and $A_1$ are constructed by a $C'$-computable list of finite approximations $A_{i,0} \subseteq A_{i,1} \subseteq \ldots$ such that all elements added to $A_{i,s+1}$ from $A_{i,s}$ are strictly greater than the maximum of $A_{i,s}$ (in the $\mathbb{N}$ order) for each $i < 2$. We then let $A_i = \bigcup_s A_{i,s}$ which will be a $\Delta_2^0 C$ set. At stage $0$, set $A_{0,0} = A_{1,0} = \emptyset$. Suppose that at stage $s$, we have defined two disjoint finite sets $A_{0,s}$ and $A_{1,s}$ such that

1. $A_{0,s} \cup A_{1,s} = [0, b]_{\mathbb{N}}$, for some integer $b \geq s$
2. $\mathcal{R}_{e',k'}$ is satisfied for every $\langle e', k' \rangle < s$

Let $\mathcal{R}_{e,k}$ be the requirement such that $\langle e, k \rangle = s$. Decide $C'$-computably whether there are some $M_k$-type $\vec{T}$ and some $M_k$-valuation $V = (\vec{R}, \vec{S}) > b$ of type $\vec{T}$ such that $\varphi_e(V)$ holds. If so, $C$-effectively fetch $\vec{T} = T_0, \ldots, T_{n-1}$ and such a $(\vec{R}, \vec{S}) > b$. Let $d$ be an upper bound (in the $\mathbb{N}$ order) on the rationals in $(\vec{R}, \vec{S})$. By Lemma 4.7, for each $i < m$, there is some $J_i \in \int_{\mathbb{Q}}(M(i))$ such that

$$(\bigcup_{j < n} T_j) \cap (\bigcup_{i < m} J_i) = \emptyset$$

Set $A_{0,s+1} = A_{0,s} \cup \bigcup_{j < m} J_i \cap \{d + b\}_{\mathbb{N}}$ and $A_{1,s+1} = [0, d]_{\mathbb{N}} \setminus A_{0,s+1}$. This way, $A_{0,s+1} \cup A_{1,s+1} = [0, d]_{\mathbb{N}}$. By the previous equation, $\bigcup_{j < n} T_j \cap \{d + b\}_{\mathbb{N}} \subseteq [0, d]_{\mathbb{N}} \setminus A_{0,s+1}$ and the requirement $\mathcal{R}_{e,k}$ is satisfied. If no such $M_k$-valuation is found, the requirement $\mathcal{R}_{e,k}$ is vacuously satisfied. Set $A_{0,s+1} = A_{0,s} \cup \{b + 1\}$ and $A_{1,s+1} = A_{1,s}$. This way, $A_{0,s+1} \cup A_{1,s+1} = [0, b + 1]_{\mathbb{N}}$. In any case, go to the next stage. This finishes the construction.

**Lemma 4.12** If $X$ is fair for some sets $A_0, A_1 \subseteq \mathbb{Q}$, then $X$ computes neither an infinite subset of $A_0$, nor a dense subset of $A_1$.

**Proof.** Since fairness is downward-closed under Turing reducibility, it suffices to prove that if $X$ is infinite and fair for $A_0, A_1$, then it intersects both $A_0$ and $A_1$.

We first prove that $X$ intersects $A_1$. Let $M$ be the 0-by-1 matrix and $\varphi(U)$ be the $\Sigma_1^0 X M$-formula which holds if $U \cap X \neq \emptyset$. The only $M$-type is $\mathbb{Q}$ and since $X$ is infinite, $\varphi$ is essential.
By fairness of \( X \), there is an \( M \)-valuation \( R \) diagonalizing against \( A_0, A_1 \) such that \( \varphi(R) \) holds. By definition of diagonalization, \( R \subseteq A_1 \). Since \( R \cap X \neq \emptyset \), this shows that \( X \cap A_1 \neq \emptyset \).

We now prove that \( X \) intersects \( A_0 \). Let \( M \) be the 1-by-0 matrix and \( \varphi(V) \) be the \( \Sigma^0_1 \) \( M \)-formula which holds if \( V \cap X \neq \emptyset \). The \( M \)-formula \( \varphi \) is essential since \( X \) is infinite. By fairness of \( X \), there is an \( M \)-valuation \( S \) diagonalizing against \( A_0, A_1 \) such that \( \varphi(S) \) holds. By definition of diagonalization, \( S \subseteq A_0 \). Since \( S \cap X \neq \emptyset \), this shows that \( X \cap A_0 \neq \emptyset \).

Note that we did not use the fact that \( X \) is dense to make sure it intersects \( A_0 \). Density will be useful in the proof of Theorem 4.14.

**Definition 4.13** A Scott set is a set \( S \subseteq 2^\omega \) such that

(i) \((\forall X \in S)(\forall Y \leq_T X)[Y \in S]\)
(ii) \((\forall X, Y \in S)[X \oplus Y \in S]\)
(iii) Every infinite, binary tree in \( S \) has an infinite path in \( S \).

**Theorem 4.14** Let \( A_0, A_1 \subseteq \mathbb{Q} \) and \( S \) be a Scott set whose members are all fair for \( A_0, A_1 \). For every set \( C \subseteq S \), every \( C \)-computable coloring \( f : [\omega]^2 \to k \), there is an infinite \( f \)-homogeneous set \( H \) such that \( H \oplus C \) computes neither an infinite subset of \( A_0 \), nor a dense subset of \( A_1 \).

**Proof.** The proof is by induction over the number of colors \( k \). The case \( k = 1 \) is ensured by Lemma 4.12. Fix a set \( C \subseteq S \) and let \( f : [\omega]^2 \to k \) be a \( C \)-computable coloring. If \( f \) has an infinite \( f \)-thin set \( H \subseteq S \), that is, an infinite set over which \( f \) avoids at least one color, then \( H \oplus C \) computes a coloring \( g : [\omega]^2 \to k-1 \) such that every infinite \( g \)-homogeneous set computes relative to \( H \oplus C \) an infinite \( f \)-homogeneous set. Since \( H \ominus C \subseteq \mathbb{S} \), by induction hypothesis, there is an infinite \( g \)-homogeneous set \( H_1 \) such that \( H_1 \oplus H \ominus C \) computes neither an infinite subset of \( A_0 \), nor a dense subset of \( A_1 \). So suppose that \( f \) has no infinite \( f \)-thin set in \( \mathbb{S} \).

We construct \( k \) infinite sets \( G_0, \ldots, G_{k-1} \). We need therefore to satisfy the following requirements for each \( p \in \omega \).

\[ N_p : (\exists q_0 > p)[q_0 \in G_0] \land \cdots \land (\exists q_{k-1} > p)[q_{k-1} \in G_{k-1}] \]

Furthermore, we want to ensure that one of the \( G \)'s computes neither an infinite subset of \( A_0 \), nor a dense subset of \( A_1 \). To do this, we will satisfy the following requirements for every \( k \)-tuple of integers \( e_0, \ldots, e_{k-1} \).

\[ Q_e : R_{e_0}^{G_0} \lor \cdots \lor R_{e_{k-1}}^{G_{k-1}} \]

where \( R_e^{H} \) holds if \( W_e^{H \ominus C} \) is neither an infinite subset of \( A_0 \), nor a dense subset of \( A_1 \).

We construct our sets \( G_0, \ldots, G_{k-1} \) by forcing. Our conditions are variants of Mathias conditions \( (F_0, \ldots, F_{k-1}, X) \) such that each \( X \) is an infinite set in \( S \), each \( F_i \) is a finite set with \( \max(F_i) < \min(X) \), and the following property holds:

\( (P) \ (\forall i < k)(\forall x \in X)[F_i \cup \{x\} \text{ is } f \text{-homogeneous with color } i] \)

A condition \( d = (E_0, \ldots, E_{k-1}, Y) \) extends \( c = (F_0, \ldots, F_{k-1}, X) \) if \( (E_i, Y) \) Mathias extends \( (F_i, X) \) for every \( i < k \). We now prove the progress lemma, stating that we can force the \( G \)'s to be infinite. This is where we use the fact that there is no infinite \( f \)-thin set in \( \mathbb{S} \).

**Lemma 4.15** For every condition \( c = (F_0, \ldots, F_{k-1}, X) \), every \( i < k \) and every \( p \in \omega \) there is some extension \( d = (E_0, \ldots, E_{k-1}, Y) \) such that \( E_i \cap (p, +\infty] \neq \emptyset \).

**Proof.** Fix \( c, i \) and \( p \). If for every \( x \in X \cap (p, +\infty] \) and almost every \( y \in X \), \( f(x, y) \neq i \), then \( X \) computes an infinite \( f \)-thin set, contradicting our hypothesis. Therefore, there is some \( x \in X \cap (p, +\infty) \) such that \( f(x, y) = i \) for infinitely many \( y \in X \). Let \( Y \) be the collection of such \( y \)'s. The condition \( (F_0, \ldots, F_{i-1}, F \cup \{x\}, F_{i+1}, \ldots, F_k, Y) \) is the desired extension.

We now prove the core lemma stating that we can satisfy each \( Q \)-requirement. A condition \( c \) forces a requirement \( Q \) if \( Q \) holds for every set \( G \) satisfying \( c \).
Lemma 4.16 For every condition \( c = (F_0, \ldots, F_{k-1}, X) \) and every \( k \)-tuple of indices \( \vec{e} \), there is an extension \( d = (E_0, \ldots, E_{k-1}, Y) \) forcing \( \mathbb{Q}_c \).

Proof. We can assume that \( W_{F_i}^{c_i} \) has already outputted at least \( k \) elements and is either included in \( A_0 \) or in \( A_1 \) for each \( i < k \). Indeed, if \( c \) has no extension satisfying this condition, then \( c \) forces \( W_{F_i}^{c_i} \) to be finite or not to be a valid solution for some \( i < k \) and therefore forces \( Q_c \). For each \( i < k \), we associate the label \( \ell_i < 2 \) and the number \( p_i \) such that \( W_{F_i}^{c_i} \) is the \((p_i + 1)\)th set of this form included in \( A_i \).

Let \( n \) be the number of sets \( W_{F_i}^{c_i} \) which are included in \( A_0 \), and let \( M \) be the \((k - n)\)-by-\( n \) matrix such that the \( j \)th row is composed of the \( n \) first elements already outputted by the set \( W_{F_i}^{c_i} \) where \( p_i = j \) and \( \ell_i = 1 \). In other words, \( M(j) \) are the \( n \) first elements outputted by the \( j \)th set \( W_{F_i}^{c_i} \) included in \( A_1 \).

Let \( \varphi(\vec{U}, \vec{V}) \) be the \( \Sigma^0_1 \times X^{\mathbb{C}} \) formula which holds if there is a finite set \( Z \subseteq X \) such that for every \( k \)-partition \( Z_0 \cup \cdots \cup Z_{k-1} = Z \), there are some \( i < k \) and some set \( E \subseteq Z_i \) which is \( f \)-homogeneous with color \( i \) and such that either \( \ell_i = 0 \) and \( W_{F_i}^{c_i} \cap U_{p_i} \neq \emptyset \), or \( \ell_i = 1 \) and \( W_{F_i}^{c_i} \cap V_{p_i, I} \neq \emptyset \) for each \( I \in \text{int}_Q(M(p_i)) \). We have two cases.

In the first case, \( \varphi(\vec{U}, \vec{V}) \) is essential. Since \( X \oplus C \) is fair for \( A_0, A_1 \), there is an \( M \)-valuation \( (\vec{R}, \vec{S}) \) diagonalizing against \( A_0, A_1 \) such that \( \varphi(\vec{R}, \vec{S}) \) holds. By compactness and definition of diagonalization against \( A_0, A_1 \), there is a finite subset \( D \subseteq X \) such that for every \( k \)-partition \( D_0 \cup \cdots \cup D_{k-1} = D \), there are some \( i < k \) and some finite set \( E \subseteq D_i \) which is \( f \)-homogeneous with color \( i \) and such that either \( \ell_i = 0 \) and \( W_{F_i}^{c_i} \cap A_1 \neq \emptyset \), or \( \ell_i = 1 \) and \( W_{F_i}^{c_i} \cap A_0 \neq \emptyset \).

Each \( y \in X \setminus D \) induces a \( k \)-partition \( D_0 \cup \cdots \cup D_{k-1} \) of \( D \) by setting \( D_i = \{ x \in D : f(x, y) = i \} \). Since there are finitely many possible \( k \)-partitions of \( D \), there are a \( k \)-partition \( D_0 \cup \cdots \cup D_{k-1} = D \) and an infinite \( X \)-computable set \( Y \subseteq X \) such that

\[
(\forall i < k)(\forall y \in D_i)(\forall y \in Y)[f(x, y) = i]
\]

We furthermore assume that \( \min(Y) \) is larger than the use of the computations. Let \( i < k \) and \( E \subseteq D_i \) be the \( f \)-homogeneous set with color \( i \) such that either \( \ell_i = 0 \) and \( W_{F_i}^{c_i} \cap A_1 \neq \emptyset \), or \( \ell_i = 1 \) and \( W_{F_i}^{c_i} \cap A_0 \neq \emptyset \). The condition \( (F_0, \ldots, F_{i-1}, F_i \cup E, F_{i+1}, \ldots, F_{k-1}, Y) \) is an extension of \( c \) forcing \( Q_c \) by the \( i \)th side.

In the second case, there is some threshold \( s \in \omega \) such that for every \( M \)-type \( \vec{T} \), there is no \( M \)-valuation \( (\vec{R}, \vec{S}) > s \) of type \( \vec{T} \) such that \( \varphi(\vec{R}, \vec{S}) \) holds. By compactness, it follows that for every \( M \)-type \( \vec{T} \), the \( \Pi^0_1 \times X^{\mathbb{C}} \) class \( \mathcal{C}_T \) of all \( k \)-partitions \( Z_0 \cup \cdots \cup Z_{k-1} = X \) such that for every \( i < k \) and every finite set \( E \subseteq Z_i \) which is \( f \)-homogeneous with color \( i \), either \( \ell_i = 0 \) and \( W_{F_i}^{c_i} \cap T_{p_i} \cap (s, +\infty)_N = \emptyset \), or \( \ell_i = 1 \) and \( W_{F_i}^{c_i} \cap I \cap (s, +\infty)_N = \emptyset \) for some \( I \in \text{int}_Q(M(p_i)) \) is non-empty. Since \( S \) is a Scott set, for each \( M \)-type \( \vec{T} \), there is a \( k \)-partition \( \vec{Z}^\vec{T} \subseteq \mathcal{C}_T \) such that \( \bigoplus_{\vec{T}} \vec{Z}^\vec{T} \oplus X \oplus C \subseteq S \).

If there are some \( M \)-type \( \vec{T} \) and some \( i < k \) such that \( \ell_i = 1 \) and \( \vec{Z}^\vec{T} \) is infinite, then the condition \( (F_0, \ldots, F_{k-1}, \vec{Z}^\vec{T}) \) extends \( X \) and forces \( W_{F_i}^{c_i} \) not to be dense. So suppose that it is not the case. Let \( Y \in \mathcal{S} \) be an infinite subset of \( X \) such that for each \( M \)-type \( \vec{T} \), there is some \( i < k \) such that \( Y \subseteq Z_i^\vec{T} \). Note that by the previous assumption, \( \ell_i = 0 \) for every such \( i \). We claim that the condition \( (F_0, \ldots, F_{k-1}, Y) \) forces \( W_{F_i}^{c_i} \) to be finite for some \( i < k \) such that \( \ell_i = 0 \). Suppose for the sake of contradiction that there are some rationals \( x_0, \ldots, x_{n-1} > s \) such that \( x_{p_i} \in W_{F_i}^{c_i} \) for each \( i < k \) where \( \ell_i = 0 \). Since \( x_0, \ldots, x_{n-1} > s, x_0, \ldots, x_{n-1} \in \bigcup \text{int}_Q(M) \). Therefore, by Lemma 4.6, let \( \vec{T} \) be the unique \( M \)-type such that \( x_j \in T_j \) for each \( j < n \). By assumption, there is some \( i < k \) such that \( Y \subseteq Z_i^\vec{T} \) and \( \ell_i = 0 \). By definition of \( Z_i^\vec{T} \), \( W_{F_i}^{c_i} \cap T_{p_i} \cap (s, +\infty)_N = \emptyset \), contradicting \( x_{p_i} \in W_{F_i}^{c_i} \).

Using Lemma 4.15 and Lemma 4.16, define an infinite descending sequence of conditions \( c_0 = (\emptyset, \ldots, \emptyset, \omega) \geq c_1 \geq \ldots \) such that for each \( s \in \omega \)
that, they share a disjoint extension commitment with a case analysis.

where $c_s = (F_{0,s}, \ldots, F_{k-1,s}, X_s)$. Let $G_i = \bigcup_s F_{i,s}$ for each $i < k$. The $G_i$’s are all infinite by (i) and $G_i$ does not compute an $a$-$\text{ER}_2^1$-solution to the $A$’s for some $i < k$ by (ii). This finishes the proof of Theorem 4.14. \qed

We are now ready to prove the main theorem.

**Proof of Theorem 4.2.** By the low basis theorem [11], there is a low set $P$ of PA degree. By Scott [18], every PA degree bounds a Scott set. Let $S$ be a Scott set such that $X \leq_T P$ for every $X \in S$. By Lemma 4.11, there is a $\Delta^0_2$ (hence $\Delta^0_2$) partition $A_0 \cup A_1 = \mathbb{Q}$ such that $P$ is fair for $A_0$, $A_1$. In particular, every set $X \in S$ is fair for $A_0$, $A_1$ since fairness is downward-closed under the Turing reducibility.

By Schoenfield’s limit lemma [20], there is a computable function $h : [\mathbb{Q}]^2 \to 2$ such that for each $x \in \mathbb{Q}$, $\lim_s h(x,s)$ exists and $x \in A_{\lim_s h(x,s)}$. Note that for every infinite set $D$ $0$-homogeneous for $h$, $D \subseteq A_0$, and for every dense set $D$ $1$-homogeneous for $h$, $D \subseteq A_1$.

Fix a computable $\text{RT}_2^2$-instance $f : [\omega]^2 \to k$. In particular, $f \in S$. By Theorem 4.14, there is an infinite $f$-homogeneous set $H$ such that $H$ computes neither an infinite subset of $A_0$, nor a dense subset of $A_1$. Therefore, $H$ computes no $\text{ER}_2^1$-solution to $h$. \qed

5. Discussion and Questions

This Erdős-Rado theorem shares an essential feature with another strengthening of Ramsey’s theorem for pairs already studied in reverse mathematics: the tree theorem for pairs [2, 3, 5, 15].

**Definition 5.1** (Tree theorem) We denote by $[2^{<\mathbb{N}}]^n$ the collection of *linearly ordered* subsets of $2^{<\mathbb{N}}$ of size $n$. A set $S \subseteq 2^{<\mathbb{N}}$ is order isomorphic to $2^{<\mathbb{N}}$ (written $S \cong 2^{<\mathbb{N}}$) if there is a bijection $g : 2^{<\mathbb{N}} \to S$ such that for all $\sigma, \tau \in 2^{<\mathbb{N}}$, $\sigma \preceq \tau$ if and only if $g(\sigma) \preceq g(\tau)$. Given a coloring $f : [2^{<\mathbb{N}}]^n \to k$, a tree $S$ is $f$-homogeneous if $S \cong 2^{<\mathbb{N}}$ and $f|[S]^n$ is monochromatic.

$\text{TT}_k^1$ is the statement “Every coloring $f : [2^{<\mathbb{N}}]^n \to k$ has an $f$-homogeneous tree.”

Both $\text{TT}_2^2$ and $\text{ER}_2^1$ lie between the arithmetic comprehension axiom and $\text{RT}_2^2$, but more than that, they share a disjoint extension commitment. Let us try to explain this informal notion with a case analysis.

Suppose we want to construct a computable $\text{RT}_2^1$-instance $f : \mathbb{N} \to 2$ which diagonalizes against two opponents $W^f$ and $W'_f$. After some finite amount of time, each opponent $W^f_i$ will have outputted a finite approximation of a solution to $f$, that is, a finite $f$-homogeneous set $F_i$. The two opponents share a common strategy. $W^f_0$ tries to build an infinite $f$-homogeneous set $H_0$ for color 0, and $W^f_1$ tries to build an infinite $f$-homogeneous set $H_1$ for color 1. It is therefore difficult to defeat both opponents at the same time, since if from now on we set $f(x) = 1$, $W^f_1$ will succeed in extending $F_1$ to an infinite $f$-homogeneous set, and if we always set $f(x) = 0$, $W^f_0$ will succeed with its dual strategy.

Consider now the same situation, where we want to construct a computable $\text{TT}_2^1$-instance $f : 2^{<\mathbb{N}} \to 2$. After some time, the opponent $W^f_0$ will have outputted a finite tree $S_0 \cong 2^{<b}$ which is $f$-homogeneous for color 0, and the opponent $W^f_1$ will have done the same with a finite tree $S_1 \cong 2^{<b}$ $f$-homogeneous for color 1. The main difference with the $\text{RT}_2^1$ case is that each opponent will commit to extend each leaf of his finite tree $S_i$ into an infinite tree isomorphic to $2^{<\mathbb{N}}$. In particular, for each tree $S_i$, the sets $X_\sigma$ of nodes extending the leaf $\sigma \in S_i$ are pairwise disjoint. Therefore, each opponent commits to extend its partial solution to disjoint sets. Moreover, by asking $b$ to be large enough, each opponent will commit to extend enough pairwise disjoint sets so that we can choose two of them for each opponent and operate the diagonalization without any conflict.

This combinatorial property works in the same way for $\text{ER}_1^1$-instances. Indeed, in this case, each opponent will commit to extend its partial solution to pairwise disjoint intervals due to the
density requirement of an ER\(^1\)-solution. Since the combinatorial arguments of the Erdős-Rado theorem and the tree theorem for pairs are very similar, one may wonder whether they are equivalent in reverse mathematics.

**Question 5.2** How do ER\(^2\)\(_2\) and TT\(^2\)\(_2\) compare over RCA\(_0\)?

The failure of Seetapun’s argument for ER\(^2\)\(_2\) comes from this disjoint extension commitment feature. In particular, it is hard to find a forcing notion for ER\(^2\)\(_2\) whose conditions are extendible.

**Question 5.3** Does ER\(^2\)\(_2\) imply ACA\(_0\) over RCA\(_0\)?

ER\(^1\) and TT\(^1\) have the same state of the art due to their common combinatorial flavor. However, when looking at their statements for pairs, ER\(^2\)\(_2\) and TT\(^2\)\(_2\) have a fundamental difference: ER\(^2\)\(_2\) has only a half disjoint extension commitment feature. This weaker property prevents one from separating RT\(^2\)\(_2\) from ER\(^2\)\(_2\) over RCA\(_0\) by adapting the argument of TT\(^2\)\(_2\) in [15].

**Question 5.4** Does RT\(^2\)\(_2\) imply ER\(^2\)\(_2\) over RCA\(_0\)?

We have seen in section 3 that the separation of BΣ\(^0\)\(_2\) from ER\(^1\) is directly adaptable from the separation of BΣ\(^0\)\(_2\) from TT\(^1\) from Corduan, Groszek, and Miletí [3], since the combinatorial core of this separation comes from this shared disjoint extension commitment. It is natural to conjecture that the status of ER\(^1\) with respect to IΣ\(^0\)\(_2\) will be the same as TT\(^1\).

**Question 5.5** Does ER\(^1\) imply IΣ\(^0\)\(_2\) over RCA\(_0\)?

It is worth mentioning that RCA\(_0\) + IΣ\(^0\)\(_2\) proves a strengthening of both TT\(^1\) and ER\(^1\), namely the statement “For every \(n\) and every \(f : 2^{<\omega} \rightarrow n\) there exists a strong copy \(S\) of the full binary tree such that \(f\) is constant on \(S\)” , where by strong copy we mean an isomorphic copy of \(2^{<\omega}\) with respect to order and minima. It is easy to see that a strong copy computes a dense set of \(2^{<\omega}\), when \(2^{<\omega}\) is equipped with the standard dense linear ordering on binary strings, i.e., the only linear order such that \(\{\tau : \tau \geq \sigma^{-1}\} <_Q \sigma <_Q \{\tau : \tau \geq \sigma^{-1}\}\) for all \(\sigma \in 2^{<\omega}\). It is likely that if we can separate TT\(^1\) or ER\(^1\) from IΣ\(^0\)\(_2\), then we can already separate this stronger statement by essentially the same proof.
