A differential approach to the multi-marginal
Schrödinger system

Guillaume Carlier∗ Maxime Laborde †

November 12, 2018

Abstract

We develop an elementary and self-contained differential approach, in an \(L^\infty\) setting, for well-posedness (existence, uniqueness and smooth dependence with respect to the data) for the multi-marginal Schrödinger system which arises in the entropic regularization of optimal transport problems.

Keywords: Multi-marginal Schrödinger system, local and global inverse function theorems, entropy minimization.

MS Classification: 45G15, 49K40.

1 Introduction

Multi-marginal optimal transport problems arise in various applied settings such as economics, quantum chemistry, Wasserstein barycenters... Contrary to the well-developed two-marginals theory (see the textbooks of Villani [13, 12] and Santambrogio [10]), the structure of solutions of such problems is far from being well-understood in general. This explains the need for good numerical/approximation methods among which the entropic approximation (which has its roots in the seminal paper of Schrödinger [11]) method plays a distinguished role both for its simplicity and its efficiency, see Cuturi [6],

Benamou et al. [1]. Roughly speaking, as its name indicates, the entropic approximation strategy consists in approximating the initial optimal transport problem by the minimization of a relative entropy with respect to the Gibbs kernel associated to the transport cost. Rigorous $\Gamma$-convergence results as well as dynamic formulations for the quadratic transport cost were studied in particular by Léonard, see [8], [9] and the references therein.

At least formally, joint measures that minimize a relative entropy subject to marginal constraints have a very simple structure, their density is the reference kernel multiplied by the tensor product of potentials (which we will call Schrödinger potentials) which are constrained by the prescribed marginal conditions. However, the existence and regularity of Schrödinger potentials cannot be taken for granted as a direct consequence of Lagrange duality because of constraints qualification issues. The problem at stake is a system of nonlinear integral equations where the data are the kernel and the marginals and the unknowns are the Schrödinger potentials. In the two-marginals case, there is a very elegant contraction argument for the Hilbert projective metric which shows the well-posedness of this system, see in particular Borwein, Lewis and Nussbaum [3]. This contraction argument is constructive and gives linear-convergence of the Sinkhorn algorithm which consists in solving alternatively the two integral equations of the system. It is not obvious to us though whether this approach can be extended to the multi-marginal case (for which existence results exist but, apart from the case of finitely supported measures, rely on rather involved and abstract arguments, see for instance Borwein and Lewis [2]). Our goal is to give an elementary differential proof of the well-posedness of the Schrödinger system in an $L^\infty$ setting.

This short paper is organized as follows. Section 2 is devoted to the presentation of the multi-marginal Schrödinger system and its variational interpretation. Section 3 deals with local invertibility whereas section 4 is devoted to global invertibility and well-posedness. Section 5 gives some further properties of the Schrödinger map.

2 Preliminaries

2.1 Data and assumptions

We are given an integer $N \geq 2$, $N$ probability spaces $(X_i, \mathcal{F}_i, m_i)$, $i = 1, \ldots, N$ and set

$$X := \prod_{i=1}^{N} X_i, \mathcal{F} := \bigotimes_{i=1}^{N} \mathcal{F}_i, m := \bigotimes_{i=1}^{N} m_i.$$  \hfill (2.1)
Given $i \in \{1, \ldots, N\}$, we will denote by $X_{-i} := \prod_{j \neq i}^N X_j$, $m_{-i} := \otimes_{j \neq i}^N m_j$ and will always identify $X$ to $X_i \times X_{-i}$ i.e. will denote $x = (x_1, \ldots, x_N) \in X$ as $x = (x_i, x_{-i})$.

We shall denote by $L_{++}^\infty(X_i, F_i, m_i)$ (respectively $L_{++}^\infty(X, F, m)$) the interior of the positive cone of $L_{+}^\infty(X_i, F_i, m_i)$ (respectively $L_{+}^\infty(X, F, m)$) and consider a kernel $K \in L_{++}^\infty(X, F, m)$ as well as densities $\mu_i \in L_{++}^\infty(X_i, F_i, m_i)$ with the same total mass:

$$\int_{X_i} \mu_i dm_i = \int_{X_j} \mu_j dm_j, \quad i, j \in \{1, \ldots, N\}. \quad (2.2)$$

Our aim is to show the well-posedness of the multi-marginal Schrödinger system: find potentials $\varphi_i$ in $L^\infty(X_i, F_i, m_i)$ (called Schrödinger potentials) such that for every $i$ and $m_i$-almost every $x_i \in X_i$ one has:

$$\mu_i(x_i) = e^{\varphi_i(x_i)} \int_{X_{-i}} K(x_i, x_{-i}) e^{\sum_{j \neq i} \varphi_j(x_j)} dm_{-j}(x_{-j}). \quad (2.3)$$

Clearly if $\varphi = (\varphi_1, \ldots, \varphi_N)$ solves (2.3) so does every family of potentials of the form $(\varphi_1 + \lambda_1, \ldots, \varphi_N + \lambda_N)$ where the $\lambda_i$’s are constants with zero-sum, it is therefore natural to add as a normalization conditions to (2.3) the additional $N - 1$ linear equations:

$$\int_{X_i} \varphi_i dm_i = 0, \quad i = 1, \ldots, N - 1. \quad (2.4)$$

### 2.2 Variational interpretation

It is worth here recalling the origin of the Schrödinger system in terms of minimization problems with multi-marginal constraints. Given $\mu = (\mu_1, \ldots, \mu_N) \in \prod_{i=1}^N L^\infty(X_i, F_i, m_i)$ satisfying (2.2), consider the entropy minimization problem:

$$\inf_{q \in \Pi(\mu)} H(q|Km) \quad (2.5)$$

where $\Pi(\mu)$ is the set of measures on $X$ having marginals $(\mu_1 m_1, \ldots, \mu_N m_N)$ (the nonemptiness of this set being guaranteed by (2.2)), $Km$ denotes the measure (equivalent to $m$) having density $K$ with respect to $m$ and $H$ denotes the relative entropy:

$$H(q|Km) := \begin{cases} \int_X \left( \log \left( \frac{dq}{\kappa dm} \right) - 1 \right) dq & \text{if } q \ll m \\ +\infty & \text{otherwise.} \end{cases}$$
A motivation for (2.5) is the following, when \( K = e^{-\tau} \) is the Gibbs kernel associated to some cost function \( c \) and \( \varepsilon > 0 \) is a small (temperature) parameter, then (2.5) is an approximation of the multi-marginal optimal transport problem which consists in finding a measure in \( \Pi(\mu) \) making the average of the cost \( c \) minimal (see [8], [9], [5]).

At least formally, (2.5) is dual to the concave unconstrained maximization problem

\[
\sup_{\varphi = (\varphi_1, \ldots, \varphi_N)} \sum_{i=1}^{N} \int_{X_i} \varphi_i \mu_i dm_i - \int_{X} K(x) e^{\sum_{j=1}^{N} \varphi_j(x_j)} dm(x)
\]  

and if \( \varphi \in \prod_{i=1}^{N} L^\infty(X_i, F_i, m_i) \) solves (2.6) (the point is that the existence of such a minimizer cannot be taken for granted) it is a critical point of the (differentiable) functional in (2.6) which exactly leads to the Schrödinger system (2.3). Moreover interpreting such a \( \varphi \) as a family of Lagrange multipliers associated to the marginal constraints in (2.5) leads to the guess that the solution \( q \) of (2.5) should be of the form \( q = \gamma m \) with a density kernel \( \gamma \) of the form

\[
\gamma(x_1, \ldots, x_N) = K(x_1, \ldots, x_N) e^{\sum_{j=1}^{N} \varphi_j(x_j)}
\]  

and the requirement that \( q \in \Pi(\mu) \) also leads to (2.3). Of course, by concavity, if \( \varphi \) is a bounded solution of (2.3) it is a maximizer of (2.6) and \( q = \gamma m \) given by (2.7) solves (2.5).

### 3 Local invertibility

Let us define

\[
E := \left\{ \varphi := (\varphi_1, \ldots, \varphi_N) \in \prod_{i=1}^{N} L^\infty(X_i, F_i, m_i) : \int_{X_i} \varphi_i dm_i = 0, i = 1, \ldots, N - 1 \right\}
\]

which, equipped with the \( L^\infty \) norm, is a Banach space. For \( \varphi = (\varphi_1, \ldots, \varphi_N) \in \prod_{i=1}^{N} L^\infty(X_i, F_i, m_i) \) define \( T(\varphi) = (T_1(\varphi), \ldots, T_N(\varphi)) \in \prod_{i=1}^{N} L^\infty(X_i, F_i, m_i) \) by

\[
T_i(\varphi)(x_i) := \int_{X_{-i}} K(x_i, x_{-i}) e^{\sum_{j=1}^{N} \varphi_j(x_j)} dm_{-i}(x_{-i}).
\]  

Note that \( T(E) = T(\prod_{i=1}^{N} L^\infty(X_i, F_i, m_i)) \subset F_{++} \) where

\[
F_{++} := F \cap \prod_{i=1}^{N} L^\infty_{++}(X_i, F_i, m_i),
\]  

4

and
\[ F := \left\{ \mu \in \prod_{i=1}^{N} L^\infty(X_i, F_i, m_i) : \int_{X_1} \mu_1 dm_1 = \ldots = \int_{X_N} \mu_N dm_N \right\}. \tag{3.3} \]

It will also be convenient to define the map \( \tilde{T} = (\tilde{T}_1, \ldots, \tilde{T}_N) \) by \( \tilde{T}_i(\varphi) := \log(T_i(\varphi)) \) for \( \varphi = (\varphi_1, \ldots, \varphi_N) \in \prod_{i=1}^{N} L^\infty(X_i, F_i, m_i) \) i.e.
\[ \tilde{T}_i(\varphi)(x_i) := \varphi_i(x_i) + \log \left( \int_{X_{-i}} K(x_i, x_{-i}) e^{\sum_{j\neq i} \varphi_j(x_j)} dm_{-i}(x_{-i}) \right). \tag{3.4} \]

Let us then observe that both \( \tilde{T} \) and \( T \) are of class \( C^\infty \), more precisely for \( \varphi \) and \( h \) in \( \prod_{i=1}^{N} L^\infty(X_i, F_i, m_i) \), we have
\[ \tilde{T}_i'(\varphi)(h)(x_i) = h_i(x_i) + \frac{\int_{X_{-i}} K(x_i, x_{-i}) e^{\sum_{j\neq i} \varphi_j(x_j)} \sum_{j\neq i} h_j(x_j) dm_{-i}(x_{-i})}{\int_{X_{-i}} K(x_i, x_{-i}) e^{\sum_{j\neq i} \varphi_j(x_j)} dm_{-i}(x_{-i})} \]
and
\[ T_i'(\varphi)(h)(x_i) = e^{\tilde{T}_i(\varphi)(x_i)} \tilde{T}_i'(\varphi)(h)(x_i). \tag{3.5} \]

Let us fix \( \varphi := (\varphi_1, \ldots, \varphi_N) \in E \), observe that \( \tilde{T}'(\varphi) \) extends (and we still denote by \( \tilde{T}'(\varphi) \) this extension) to a bounded linear self map of \( \prod_{i=1}^{N} L^2(X_i, F_i, m_i) \) which is of the form
\[ \tilde{T}'(\varphi) := \text{id} + L \tag{3.6} \]
with \( L \) a compact linear self map of \( \prod_{i=1}^{N} L^2(X_i, F_i, m_i) \). We then have the following:

**Proposition 3.1.** Let \( \varphi \in E \) then \( T'(\varphi) \) is an isomorphism between \( E \) and \( F \). In particular, \( T \) is a local \( C^\infty \) diffeomorphism between \( E \) and \( F \), and \( T(E) \) is open in \( F_{++} \).

**Proof.** In view of (3.5), the desired invertibility claim amounts to show that \( \tilde{T}'(\varphi) \) is an isomorphism between \( E \) and \( F_\varphi \) the linear subspace of codimension \( N - 1 \) consisting of \( \theta = (\theta_1, \ldots, \theta_N) \in \prod_{i=1}^{N} L^\infty(X_i, F_i, m_i) \) which satisfy
\[ \int_{X_1} e^{\tilde{T}_i(\varphi)} \theta_1 dm_1 = \ldots = \int_{X_N} e^{\tilde{T}_N(\varphi)} \theta_N dm_N. \tag{3.7} \]

Let us also denote by \( F_{\varphi,2} \) the set of all \( \theta = (\theta_1, \ldots, \theta_N) \in \prod_{i=1}^{N} L^2(X_i, F_i, m_i) \) which satisfy (3.7).
As noted above, one can write $\tilde{T}'(\varphi) = \text{id} + L$ on $\prod_{i=1}^{N} L^2(X_i, \mathcal{F}_i, m_i)$ with $L$ compact. Let us define the probability measure $Q_{\varphi}$ on $X$ given by

$$Q_{\varphi}(dx) = \frac{K(x)e^{\sum_{j=1}^{N} \varphi_j(x_j)m(dx)}}{\int_X K(x)e^{\sum_{j=1}^{N} \varphi_j(x_j)}dm(x)}. \quad (3.8)$$

For $i = 1, \ldots, N$, let us now disintegrate $Q_{\varphi}$ with respect to its $i$-th marginal $Q_{\varphi}^i$:

$$Q_{\varphi}(dx_i, dx_{-i}) = Q_{\varphi}^i(dx_{-i}|x_i) \otimes Q_{\varphi}^i(dx_i) \quad (3.9)$$

where $Q_{\varphi}^{-1}(dx_{-i}|x_i)$ is the conditional probability of $x_{-i}$ given $x_i$ according to $Q_{\varphi}$. The compact operator $L$ can then conveniently be expressed in terms of the corresponding conditional expectations operators. Indeed, setting $L(h) = (L_1(h), \ldots, L_N(h))$, we obviously have

$$L_i(h)(x_i) = \int_{X_{-i}} \left( \sum_{j \neq i} h_j(x_j) \right) Q_{\varphi}^{-1}(dx_{-i}|x_i) \text{ for } m_i\text{-a.e. } x_i \in X_i.$$

Let $h \in \prod_{i=1}^{N} L^2(X_i, \mathcal{F}_i, m_i)$ be such that $\tilde{T}'(\varphi)(h) = 0$ (equivalently $T'(\varphi)(h) = 0$) i.e. for every $i$ and $m_i$-a.e. $x_i \in X_i$, there holds

$$h_i(x_i) = \int_{X_{-i}} \left( \sum_{j \neq i} h_j(x_j) \right) Q_{\varphi}^{-1}(dx_{-i}|x_i)$$

multiplying by $h_i(x_i)$ and then integrating with respect to $Q_{\varphi}^i$ gives

$$\int_{X_i} h_i^2(x_i)dQ_{\varphi}^i(x_i) = -\sum_{j \neq i} \int_{X_i} h_i(x_i)h_j(x_j)dQ_{\varphi}(x)$$

summing over $i$ thus yields

$$\int_X \left( \sum_{i=1}^{N} h_i(x_i) \right)^2dQ_{\varphi}(x) = \sum_{i=1}^{N} \int_{X_i} h_i^2(x_i)dQ_{\varphi}^i(x_i) + \sum_{i,j \neq i} \int_X h_i(x_i)h_j(x_j)dQ_{\varphi}(x) = 0.$$

Since $Q_{\varphi}$ is equivalent to $m$, we deduce that $\sum_{i=1}^{N} h_i(x_i) = 0$ $m$-a.e. that is $h$ is constant and its components sum to 0. Hence $\ker(\tilde{T}'(\varphi))$ has dimension $N - 1$ and $\ker(\tilde{T}'(\varphi)) \cap E = \{0\}$ i.e. $\tilde{T}'(\varphi)$ is one to one on $E$.

Since $L$ is a compact operator of $L^2$ and $\ker(\text{id} + L)$ has dimension $N - 1$, it follows from the Fredholm alternative Theorem (see chapter VI of [4]) that $R(\text{id} + L)$ has codimension $N - 1$. Differentiating the relation

$$\int_{X_i} e^{\tilde{T}_i(\varphi)}dm_i = \int_{X_j} e^{\tilde{T}_j(\varphi)}dm_j, \ i, j \in \{1, \ldots, N - 1\}$$
gives
\[
\int_{X_i} e^{T_i(\varphi)T_i^*(\varphi)} \mu_i = \int_{X_k} e^{T_j(\varphi)T_j^*(\varphi)} \mu_j, \quad i, j \in \{1, \ldots, N-1\}
\]
i.e. \(\tilde{T}(\varphi)(h) \in F_{\varphi}\) for every \(h \in \prod_{i=1}^{N} L^\infty(X_i, \mathcal{F}_i, m_i)\). Likewise, we also have \(\tilde{T}(\varphi)(h) \in F_{\varphi,2}\) for every \(h \in \prod_{i=1}^{N} L^2(X_i, \mathcal{F}_i, m_i)\). Since \(F_{\varphi,2}\) has codimension \(N-1\), we get
\[
R(id + L) = \tilde{T}(\varphi) \left( \prod_{i=1}^{N} L^2(X_i, \mathcal{F}_i, m_i) \right) = F_{\varphi,2}.
\] (3.10)

In particular, for every \(\theta \in F_{\varphi}\) there exists \(h \in \prod_{i=1}^{N} L^\infty(X_i, \mathcal{F}_i, m_i)\) such that \(\theta = h + L(h)\) since obviously \(L\) maps \(\prod_{i=1}^{N} L^2(X_i, \mathcal{F}_i, m_i)\) into \(\prod_{i=1}^{N} L^\infty(X_i, \mathcal{F}_i, m_i)\) we have \(h \in \prod_{i=1}^{N} L^\infty(X_i, \mathcal{F}_i, m_i)\). Finally, since \(\tilde{T}(\varphi)(h) = T^*(\varphi)(\tilde{h})\) whenever \(h - \tilde{h}\) is a vector of constants summing to zero, we may also assume that \(h \in E\). This shows that \(T^*(\varphi)(E) = F_{\varphi}\) or equivalently \(T^*(\varphi)(E) = F\).

We have shown that \(T^*(\varphi)\) is an isomorphism between the Banach spaces \(E\) and \(F\), the local invertibility claim thus directly follows from the local inversion Theorem.

\[\square\]

4 Global invertibility and well-posedness

To pass from local to global invertibility of \(T\), we invoke classical arguments à la Caccioppoli-Hadamard (see for instance [7]). First of all, it is easy to see that \(T\) is one to one on \(E\):

**Proposition 4.1.** The map \(T\) is injective on \(E\).

**Proof.** If \(\varphi\) and \(\psi\) are in \(E\) and \(T(\varphi) = T(\psi) := \mu\), then both \(\varphi\) and \(\psi\) are solutions of the maximization problem (2.6), since the functional in (2.6) is the sum of a linear term and a term that is strictly concave in the direct sum of the potentials we should have \(\sum_{i=1}^{N} \varphi_i(x_i) = \sum_{i=1}^{N} \psi_i(x_i)\) which by the normalization condition in the definition of \(E\) implies that \(\varphi = \psi\).

\[\square\]

Next we observe that:

**Lemma 4.2.** \(T(E)\) is closed in \(F_{++}\).
Proof. Let \((\varphi^n)_n \in E^N\) be such that \(\mu^n := T(\varphi^n)\) converges in \(L^\infty\) to some \(\mu \in F_{++}\). Let \(\psi^n = (\varphi^n_1 + \lambda^n_1, \ldots, \varphi^n_N + \lambda^n_N)\) where the \(\lambda^n_i\)'s are constant which sum to zero and chosen in such a way that
\[
\int_{X_i} e^{\psi^n_i} dm_i = 1, \ i = 1, \ldots, N - 1,
\]
this ensures that \(\mu^n := T(\psi^n)\) i.e. for every \(i\) and \(m_i\)-a.e. \(x_i \in X_i\)
\[
\log(\mu^n_i(x_i)) = \psi^n_i(x_i) + \log \left( \int_{X_{-i}} K(x_i, x_{-i}) q^n_{-i}(x_{-i}) dm_{-i}(x_{-i}) \right)
\]
where
\[
q^n_{-i}(x_{-i}) := e^{\sum_{j \neq i} \psi^n_j(x_j)}.
\]
Since \((\mu^n_N)_n\) is uniformly bounded and bounded away from 0 and so is \(K\), we deduce that \((e^{\psi^n_N})_n\) is bounded and bounded away from 0 in \(L^\infty\) i.e. \((\psi^n_N)_n\) is bounded in \(L^\infty(X_N, \mathcal{F}_N, m_N)\). From this \(L^\infty\) bound on \((\psi^n_N)_n\), the fact that \(K \in L^\infty_{++}(X, \mathcal{F}, m)\) and the uniform bounds from above and from below on \(\mu^n_i\), we deduce that \(\psi^n_i\) is bounded in \(L^\infty\) for \(i = 1, \ldots, N - 1\). In particular, taking subsequences if necessary, we may assume that for every \(i\), \((q^n_{-i})_n\) converges weakly * in \(L^\infty(X_{-i}, \mathcal{F}_{-i}, m_{-i})\) to some \(q_{-i}\), in particular \(\int_{X_{-i}} K(x_i, x_{-i}) q^n_{-i}(x_{-i}) dm_{-i}(x_{-i})\) converges for \(m_i\)-a.e. \(x_i\) to \(\int_{X_{-i}} K(x_i, x_{-i}) q_{-i}(x_{-i}) dm_{-i}(x_{-i})\). But since \(\log(\mu^n_i)\) converges in \(L^\infty(X_i, \mathcal{F}_i, m_i)\) to \(\log(\mu_i)\), we deduce from \((4.2)\) that \(\psi^n_i\) converges \(m_i\)-a.e. (and also in \(L^p\) for every \(p \in [1, +\infty)\) by Lebesgue’s dominated convergence Theorem) to some \(\psi_i \in L^\infty\). Passing to the limit in \((4.2)\), we then have \(\mu = T(\psi)\) or equivalently \(\mu = T(\varphi)\) for \(\varphi \in E\) such that \(\varphi - \psi\) is constant. This shows that \(T(E)\) is closed in \(F_{++}\).

We are now in position to state our main result:

**Theorem 4.3.** For every \(\mu \in F_{++}\), the multi-marginal Schrödinger system \((Z, \mathcal{H})\) admits a unique solution \(\varphi = S(\mu) \in E\), moreover \(S \in C^\infty(F_{++}, E)\).

**Proof.** It follows from Proposition 3.1 that \(T(E)\) is open in \(F_{++}\) and Lemma 4.2 ensures it is closed in \(F_{++}\), since \(F_{++}\) is connected (it is actually convex) we deduce that \(T(E) = F_{++}\). Together with Proposition 4.1 this implies that \(T\) is a bijection between \(E\) and \(F_{++}\), the smoothness claim then follows from Proposition 3.1. 

\[ \square \]
5 Further properties of the Schrödinger map

From now on, we refer to the smooth map $S = T^{-1} : F_{++} \to E$ from Theorem 4.3 as the Schrödinger map. Our aim now is to study the (local) Lipschitz behavior of $S$. Given $M \geq 1$ we define

$$F_{++,M} := \{ \mu \in F_{++} : \frac{1}{M} \leq \mu_i \leq M \text{ m}_i\text{-a.e.} \}. \quad (5.1)$$

Let us start with an elementary a priori bound:

**Lemma 5.1.** For every $M \geq 1$ there is a constant $R_M$ such that $S(F_{++,M})$ is included in the ball of radius $R_M$ of $\prod_{i=1}^{N} L^\infty(X_i, F_i, m_i)$.

**Proof.** Let $\mu \in F_{++,M}$ and $\varphi = S(\mu)$, as in the proof of Lemma 4.2 we introduce constants $\lambda_i$ with zero sum such that $\mu = T(\psi)$ with $\psi_i = \varphi_i + \lambda_i$ is normalized by (4.1) (instead of (2.4)). Using the fact that $K$ is bounded and bounded away from 0, that $M^{-1} \leq \mu_N \leq M$, (4.1) and $\mu_N = T_N(\psi)$ gives upper and lower bounds on $e^{v_N \psi}$ i.e. an $L^\infty$ bound (depending on $M$ and $K$ only) on $\psi_N$. This bound and $\mu_i = T_i(\psi)$ in turn provide $L^\infty$ bounds on $\psi_i$ for $i = 1, \ldots, N - 1$. Finally, we get bounds on the constants $\lambda_i$ since $\lambda_i = \int_{X_i} \psi_i dm_i$ for $i = 1, \ldots, N - 1$ and $\lambda_N = -\sum_{i=1}^{N-1} \lambda_i$. This gives the desired bounds on $\varphi = S(\mu)$.

More interesting in possible applications, is the Lipschitz behavior of $S$ given by the following

**Theorem 5.2.** For every $M \geq 1$ there is a constant $C_M$, such that for every $\mu$ and $\nu$ in $F_{++,M}$, there holds

$$\|S(\mu) - S(\nu)\|_{L^2} \leq C_M \|\mu - \nu\|_{L^2}, \quad (5.2)$$

and

$$\|S(\mu) - S(\nu)\|_{L^\infty} \leq C_M \|\mu - \nu\|_{L^\infty}. \quad (5.3)$$

**Proof.** Let $\mu \in F_{++,M}$ and $\varphi = S(\mu) \in E$, our aim is to estimate the operator norm of $S'(\mu) = [T'(\varphi)]^{-1}$ (first in $L^2$ and then in $L^\infty$). Let $\theta \in F$ and $h = S'(\mu)\theta$ i.e. $T'(\varphi)h = \theta$ which can be rewritten as

$$\tilde{T}'(\varphi)h = \tilde{\theta} \text{ with } \tilde{\theta}_i := \frac{\theta_i}{\mu_i}. \quad (5.4)$$

\footnote{In formulas (5.2) (respectively (5.3)) $L^2$ (resp. $L^\infty$) is a abbreviated notation for $\prod_{i=1}^{N} L^2(X_i, F_i, m_i)$ (resp. $\prod_{i=1}^{N} L^\infty(X_i, F_i, m_i)$).}
Defining the measure $Q_\varphi$ by (3.8) and disintegrating it with respect to its $i$-th marginal as in (3.9) in the proof of proposition 3.1 gives that for every $i$ and $m_i$-a.e. $x_i$ one has
\[
\tilde{\theta}_i(x_i) = h_i(x_i) + \int_{X_i} \bigg( \sum_{j \neq i} h_j(x_j) \bigg) Q^{-i}_\varphi(dx_i|x_i).
\] (5.5)

We then argue in a similar way as we did in the proof of proposition 3.1, multiplying (5.5) by $h_i$ and integrating with respect to $Q^i_\varphi$ and summing over $i$, we obtain
\[
\sum_{i=1}^N \int_{X_i} \tilde{\theta}_i(x_i) h_i(x_i) dQ^i_\varphi(x_i) = \int_X \bigg( \sum_{j=1}^N h_j(x_j) \bigg)^2 dQ_\varphi(x). \quad (5.6)
\]

Next we observe that thanks to the fact that $\mu \in F_{++,M}$, the upper and lower bounds on $K$ and Lemma 5.1 there is a constant $\nu_M \geq 1$ such that
\[
\frac{m}{\nu_M} \leq Q_\varphi \leq \nu_M m, \quad \frac{m_i}{\nu_M} \leq Q^i_\varphi \leq \nu_M m_i. \quad (5.7)
\]

Using the fact that $\|\tilde{\theta}_i\|_{L^2(X_i,F_i,m_i)} \leq M \|\theta_i\|_{L^2(X_i,F_i,m_i)}$, (5.7) and Cauchy-Schwarz inequality, we deduce from (5.6) that there is a constant $C_M$ such that
\[
\int_X \bigg( \sum_{j=1}^N h_j(x_j) \bigg)^2 dm(x) \leq C_M \sum_{i=1}^N \|\theta_i\|_{L^2(X_i,F_i,m_i)} \|h_i\|_{L^2(X_i,F_i,m_i)}. \quad (5.8)
\]

Finally recall that since $h \in E$ we have
\[
\int_X \bigg( \sum_{j=1}^N h_j(x_j) \bigg)^2 dm(x) = \sum_{j=1}^N \int_{X_j} h_j^2(x_j) dm_j(x_j) =: \|h\|_{L^2}^2
\]

hence
\[
\|h\|_{L^2} = \|S'(\mu)\theta\|_{L^2} \leq C_M \|\theta\|_{L^2} \text{ i.e. } \sup_{\mu \in F_{++,M}} \|S'(\mu)\|_{L(L^2)} \leq C_M. \quad (5.9)
\]

By the mean-value inequality (5.9) immediately gives the Lipschitz in $L^2$ estimate (5.2).

As for a bound on the operator norm of $S'(\mu)$ in $L^\infty$, we first observe that for some positive constant $\lambda_M$ we have $Q^{-i}_\varphi \leq \lambda_M m_{-i}$, so that (5.5)
\[ \| h_i \|_{L^\infty} \leq \| \tilde{\theta}_i \|_{L^\infty(m_i)} + \lambda M \sum_{j \neq i} \int_{X_j} |h_j(x_j)| dm_j(x_j) \]
\[ \leq M \| \theta_i \|_{L^\infty(m_i)} + \lambda M \sqrt{N} \| h \|_{L^2} \]
\[ \leq M \| \theta_i \|_{L^\infty(m_i)} + \lambda M \sqrt{NC_M} \| \theta \|_{L^2} \]
\[ \leq C_M' \| \theta \|_{L^\infty} \]

where we have used Cauchy-Schwarz inequality in the second line and (5.9) in the third one. This clearly implies (5.3).
