**HAL** is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

## **Metastatic osteosarcoma challenged by regorafenib**

Osteosarcomas belong to a large family of tumour entities of mesenchymal origin which exhibit heterogeneous histological, genetic and molecular features. Their pathogenesis can be explained by initial TP53 and/or RB1 somatic alterations leading to chromosomal instability, followed by secondary oncogenic events and the development of a polyclonal disease associated with the metastatic process. This genetic complexity has been illustrated by recent series of patients in which the authors have identified a considerable number of point mutations and deletions in an impressive number of genes.<sup>1</sup> It has also stimulated the development of numerous therapeutic strategies targeting tumour cells and/or their microenvironment.<sup>2</sup> The fact that osteosarcomas are both rare forms of cancer and highly heterogeneous explains why the patient survival rate has not improved in the last four decades, especially for metastatic and unresectable osteosarcomas. Regardless of whether or not the drugs used in the first line of chemotherapy (in neoadjuvant and/or adjuvant chemotherapy for 6 to 12 months) have been standardized (relatively speaking) and include doxorubicin, cisplatin, methotrexate and ifosfamide, there is no consensus on either the optimum combination or the therapeutic options for recurrent metastatic patients.<sup>3</sup>

Protein kinases are part of a large family of key enzymes that catalyse the transfer of a phosphate group from ATP to a hydroxyl group of serine or threonine. More than 50 protein kinases are receptors (receptor tyrosine kinase: RTK) and are classified into 6 classes of protein, depending on their biochemical structure.<sup>4</sup> All RTK are characterized by a single trans-membrane domain and a glycosylated N-terminal extracellular domain involved in both the dimerization mechanism of the receptors, and in the ligand recognition that triggers downstream signalling pathways, including MAPK, PI3K, Src, PLC $\gamma$ , JAK / STAT. On the basis of their diversity, and their wide-ranging expression in normal cells, cancer cells and the signalling cascades they trigger, RTK are strongly implicated in multiple pathways of cancer development. As a result, numerous RTK inhibitors have been developed by pharmaceutical companies. Imatinib mesylate (Gleevec<sup>®</sup>) was the first to demonstrate spectacular clinical benefits in chronic myeloid leukaemia (CML) patients and in gastro-intestinal stromal tumours (GIST), and it has become the standard treatment in patients with a high risk of GIST recurrence following tumour resection. Regorafenib belongs to the long list of multikinase

inhibitors with non-specific activities targeting VEGFR1/2/3, RET, Raf, PDGFR and KIT. Interestingly, in a phase I clinical trial regorafenib produced an objective response in one of three patients with a second-line advanced osteosarcoma.<sup>5</sup>

In The Lancet Oncology, Florence Duffaud *et coll.*<sup>6</sup> report the results of regorafenib in patients with advanced osteosarcoma, in a non-comparative, randomized, double-blind placebo-controlled phase 2 clinical trial. The authors observed 16-week progression-free survival (95%, CI 8.0-27.3) in the tyrosine kinase inhibitor arm and 4 weeks (95%, CI 3.0-5.7) in the placebo group. This difference was maintained over time at 12 and 24 weeks, with a non-progression rate of 35% for the patients treated with regorafenib and 0% for those on placebo. Although the present study was statistically non-comparative, it highlights the potential therapeutic value of regorafenib in cases of recurrent and unresectable osteosarcoma for which there are currently only limited therapeutic options and a pressing medical need.

So what is next? The next step will be to identify the main cellular and molecular targets in the patient population of interest. The questions are whether the therapeutic benefits of regorafenib are linked to the targeting of a single or multiple RTK, and on which cells? Are the effects of regorafenib related to direct activity on cancer cells and/or on cells present in their microenvironment? Identifying the target(s) of regorafenib is essential for moving towards better stratification of the patients enrolled in future clinical trials. In addition, approximately 30% of RTKs are overexpressed or mutated in human cancers and can be associated with drug resistance.<sup>7-9</sup> In this context, an adapted investigational strategy will be needed to obtain real and precise mapping of activated/mutated/expressed tyrosine kinase proteins.. Previous preclinical and clinical studies have underlined the risk of drug resistance and relapse related to protein point mutations and/or the establishment of molecular feedback loops after administration of RTK inhibitors, as observed in GIST.<sup>10</sup> A sequential therapeutic approach combining RTK inhibitors, chemotherapy and targeted therapies (e.g. check point inhibitors) may be an alternative for preventing/limiting acquired drug resistance. Pertinent screening of recurrent unresectable osteosarcoma patients on the basis of their RTK profiling could help prevent the development of drug resistance, and thus define the therapeutic alternatives. By increasing the homogeneity of the population studied, this type of screening will also improve the chances of success of large phase 3 clinical trials which, as recommended by the authors, should be set up at the European and international levels.
