The documents may come from teaching and research institutions in France or abroad, or from public or private research centers. L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Dependence properties and Bayesian inference for asymmetric multivariate copulas

Julyan Arbel, Marta Crispino and Stéphane Girard∗

Univ. Grenoble Alpes, Inria, CNRS, Grenoble INP, LJK, 38000 Grenoble, France

Abstract

We study a broad class of asymmetric copulas introduced by Liebscher (2008) as a combination of multiple—usually symmetric—copulas. The main thrust of the paper is to provide new theoretical properties including exact tail dependence expressions and stability properties. A subclass of Liebscher copulas obtained by combining Fréchet copulas is studied in more details. We establish further dependence properties for copulas of this class and show that they are characterized by an arbitrary number of singular components. Furthermore, we introduce a novel iterative representation for general Liebscher copulas which de facto insures uniform margins, thus relaxing a constraint of Liebscher’s original construction. Besides, we show that this iterative construction proves useful for inference by developing an Approximate Bayesian computation sampling scheme. This inferential procedure is demonstrated on simulated data.

Keywords — Approximate Bayesian computation, asymmetric copulas, dependence properties, singular components.

1 Introduction

Let \( X = (X_1, \ldots, X_d) \) be a continuous random vector with \( d \)-variate cumulative distribution function (cdf) \( F \), and let \( F_j, j \in \{1, \ldots, d\} \), be the marginal cdf of \( X_j \). According to Sklar’s theorem (Sklar, 1959), there exists a unique \( d \)-variate function \( C : [0,1]^d \to [0,1] \) such that

\[
F(x) = C(F_1(x_1), \ldots, F_d(x_d)), \quad x = (x_1, \ldots, x_d) \in \mathbb{R}^d.
\]

The function \( C \) is referred to as the copula associated with \( F \). It is the \( d \)-dimensional cdf of the random vector \((F_1(X_1), \ldots, F_d(X_d))\) with uniform margins on \([0, 1]\).

A copula is said to be symmetric (or exchangeable) if for any \( u \in [0, 1]^d \), and for any permutation \((\sigma_1, \ldots, \sigma_d)\) of the first \( d \) integers \( \{1, \ldots, d\} \), it holds that

\[
C(u_1, \ldots, u_d) = C(u_{\sigma_1}, \ldots, u_{\sigma_d}).
\]

The assumption of exchangeability may be unrealistic in many domains, including quantitative risk management (Di Bernardino and Rullière, 2016), reliability modeling (Wu, 2014), and oceanography (Zhang et al., 2018). The urge for asymmetric copula models in order to better account

*stephane.girard@inria.fr. Corresponding author.
for complex dependence structures has recently stimulated research in several directions, including Rodriguez-Lallena and Úbeda-Flores (2004), Alfonsi and Brigo (2005), Durante (2009), Wu (2014), Durante et al. (2015). We focus here on a simple yet general method for building asymmetric copulas introduced by Liebscher (2008, Theorem 2.1 and Property(i)):

**Theorem 1.** (Liebscher, 2008) Let $C_1, \ldots, C_K : [0, 1]^d \to [0, 1]$ be copulas, $g^{(k)}_j : [0, 1] \to [0, 1]$ be increasing functions such that $g^{(k)}_j(0) = 0$ and $g^{(k)}_j(1) = 1$ for all $k \in \{1, \ldots, K\}$ and $j \in \{1, \ldots, d\}$. Then,

$$u \in [0, 1]^d \mapsto \tilde{C}(u) = \prod_{k=1}^K C_k(g^{(k)}_1(u_1), \ldots, g^{(k)}_d(u_d))$$

(1)

is also a copula under the constraint that

$$\prod_{k=1}^K g^{(k)}_j(u) = u \text{ for all } u \in [0, 1] \text{ and } j \in \{1, \ldots, d\}.$$  

(2)

Theorem 1 provides a generic way to construct an asymmetric copula $\tilde{C}$, henceforth referred to as Liebscher copula, starting from a sequence of symmetric copulas $C_1, \ldots, C_K$. This mechanism was first introduced by Khoudraji (1995) in the particular case where $K = 2$ and with the functions $g^{(k)}_j$ assumed to be power functions, for each $j \in \{1, \ldots, d\}$ and $k \in \{1, \ldots, K\}$, that satisfy condition (2). The class of Liebscher copulas covers a broad range of dependencies and benefits from tractable bounds on dependence coefficients of the bivariate marginals (Liebscher, 2008, 2011, Mazo et al., 2015). However, there are two main reasons why the practical implementation of this approach is not straightforward: (i) it is not immediate to construct functions that satisfy condition (2); and (ii) the product form complicates the density computation even numerically, which makes it difficult to perform likelihood inference on the model parameters (Mazo et al., 2015).

The aim of this paper is to deepen the understanding of Liebscher’s construction in order to overcome drawbacks (i) and (ii). Our contributions in this regard are three-fold. First, we provide theoretical properties of the asymmetric copulas in (1), including exact expressions of tail dependence indices, thus complementing the partial results of Liebscher (2008, 2011). Second, we give an iterative representation of (1) which has the advantage to relax assumption (2) by automatically satisfying it. Third, we develop an inferential procedure and a sampling scheme that rely on the newly developed iterative representation.

The Bayesian paradigm proves very useful for inference in our context as it overcomes the problematic computation of the maximum likelihood estimate, which requires the maximization of a very complicated likelihood function (see recent contributions Valle et al., 2018, Ning and Shephard, 2018). General Bayesian sampling solutions in the form of Markov chain Monte Carlo are not particularly well-suited neither since they require the evaluation of that complex likelihood. Instead, we resort to Approximate Bayesian computation (ABC), a technique dedicated to models with complicated, or intractable, likelihoods (see Marin et al., 2012, Robert, 2018, Karabatsos and Leisen, 2018, for recent reviews). ABC requires the ability to sample from the model, which is straightforward with our iterative representation of Liebscher copula. The adequacy of ABC for inference in copula models was leveraged by Grazian and Liseo (2017), although in the different context of empirical likelihood estimation. A reversed approach to ours is followed by Li et al. (2017), who make use of copulas in order to adapt ABC to high-dimensional settings.
Since its introduction, the construction by Liebscher has received much attention in the copula literature (e.g. Salvadori and De Michele, 2010, Durante and Salvadori, 2010, Lauterbach and Pféifer, 2015). However, most studies have been limited to simple cases where the product in \( \Phi \) has only two terms. We hope that our paper will contribute to the further spreading of Liebscher’s copulas, because it allows to exploit their full potential by: (i) better understanding their properties; (ii) providing a novel construction, which facilitates their use with an arbitrary number \( K \) of terms in \( \Phi \); and (iii) giving a strategy to make inference on them.

On top of what presented above, an additional contribution of this paper is to derive specific results for the subclass of Liebscher’s copula when two or more Fréchet copulas are combined, which we call Liebscher–Fréchet copula. This subclass is characterized by an arbitrary number of singular components. To the best of our knowledge, this is the first paper to investigate this copula’s properties and to provide an inference procedure.

The paper is organized as follows. Section 2 provides some theoretical results concerning the properties of asymmetric Liebscher copulas, also presenting the novel iterative construction. In Section 3, we introduce and analyze the Liebscher–Fréchet copula. Section 4 is dedicated to the inference strategy and to demonstrate our approach on simulated data. We conclude with a short discussion in Section 5. Proofs are postponed to the Appendix.

2 Properties of the copula

In this section, some new properties of the copula \( \tilde{C} \) are established, complementing the ones in Liebscher (2008, 2011). Sections 2.1 and 2.2 are dedicated to (tail) dependence properties. For the sake of simplicity, we focus on the case \( d = 2 \) of bivariate copulas. Some stability properties of Liebscher’s construction are highlighted in Section 2.3. Finally, an alternative construction to Liebscher copula (1) is introduced in Section 2.4.

2.1 Tail dependence

The lower and upper tail dependence functions, denoted by \( \Lambda_L(C; \cdot) \) and \( \Lambda_U(C; \cdot) \) respectively, are defined for all \((x, y) \in \mathbb{R}_+^2\) by

\[
\Lambda_L(C; x, y) = \lim_{\varepsilon \to 0} \frac{C(\varepsilon x, \varepsilon y)}{\varepsilon}, \quad \text{and} \quad \Lambda_U(C; x, y) = x + y + \lim_{\varepsilon \to 0} \frac{C(1 - \varepsilon x, 1 - \varepsilon y) - 1}{\varepsilon},
\]

where \( C \) is a given bivariate copula, see for instance Joe et al. (2010). Note that these limits exist under a bivariate regular variation assumption, see Resnick (2013), Section 5.4.2 for details. When they exist, these functions are homogeneous (Joe et al., 2010, Proposition 2.2) i.e. for all \( t \in (0, 1] \) and \((x, y) \in \mathbb{R}_+^2\),

\[
\Lambda(C; tx, ty) = t \Lambda(C; x, y),
\]

where \( \Lambda \) is equal to \( \Lambda_L \) or \( \Lambda_U \). The lower and upper tail dependence coefficients, denoted by \( \lambda_L(C) \) and \( \lambda_U(C) \) respectively, are defined as the conditional probabilities that a random vector associated with a copula \( C \) belongs to lower or upper tail orthants given that a univariate margin
takes extreme values:

\[ \lambda_L(C) = \lim_{u \to 0} C(u, u) \quad \text{and} \quad \lambda_U(C) = 2 - \lim_{u \to 1} C(u, u) - 1. \]

These coefficients can also be interpreted in terms of the tail dependence functions: \( \lambda_L(C) = \Lambda_L(C; 1, 1) \) and \( \lambda_U(C) = \Lambda_U(C; 1, 1) \). Conversely, in view of the homogeneity property, the behavior of the tail dependence functions on the diagonal is determined by the tail dependence coefficients: \( \Lambda_L(C; t, t) = \lambda_L(C)t \) and \( \Lambda_U(C; t, t) = \lambda_U(C)t \) for all \( t \in (0, 1] \). The tail dependence functions for Liebscher copula are provided by Proposition 1 which, in view of the previous remarks, allows us to derive the tail dependence coefficients in Corollary 1. Some of these results rely on the notion of (univariate) regular variation. Recall that a positive function \( g \) is said to be regularly varying with index \( \gamma \) if

\[ \frac{g(ut)}{g(u)} \to t^\gamma \quad \text{as} \quad u \to \infty \quad \text{for all} \quad t > 0, \]

see Bingham et al. (1989).

**Proposition 1.** Let \( (x, y) \in \mathbb{R}^2_+ \) and consider \( \tilde{C} \) the bivariate copula defined by (1) with \( d = 2 \).

(i) Lower tail, symmetric case. Assume that \( g_1^{(k)}(u) = g_2^{(k)}(u) \) is a regularly varying function with index \( \gamma^{(k)} > 0 \) for all \( k \in \{1, \ldots, K\} \). Then,

\[ \Lambda_L(\tilde{C}; x, y) = \prod_{k=1}^{K} \Lambda_L(C_k; x^{\gamma^{(k)}}, y^{\gamma^{(k)}}) \]

and, necessarily, \( \sum_{k=1}^{K} \gamma^{(k)} = 1 \).

(ii) Lower tail, asymmetric case. Suppose there exists \( k_0 \in \{1, \ldots, K\} \) such that \( \frac{g_1^{(k_0)}(u)}{g_2^{(k_0)}(u)} \to 0 \) as \( u \to 0 \). Then,

\[ \Lambda_L(\tilde{C}; x, y) = 0. \]

(iii) Upper tail, general case. Assume that, for all \( k \in \{1, \ldots, K\} \), \( g_1^{(k)} \) and \( g_2^{(k)} \) are differentiable at 1, with derivative at 1 denoted by \( d_1^{(k)} \) and \( d_2^{(k)} \) respectively. Then

\[ \Lambda_U(\tilde{C}; x, y) = \sum_{k=1}^{K} \Lambda_U(C_k; d_1^{(k)}x, d_2^{(k)}y) \]

and, necessarily, \( \sum_{k=1}^{K} d_j^{(k)} = 1 \), for \( j \in \{1, 2\} \).

(iv) Upper tail, particular case. If, in addition to (iii), \( d_1^{(k)} = d_2^{(k)} = d^{(k)} \) for all \( k \in \{1, \ldots, K\} \), then

\[ \Lambda_U(\tilde{C}; x, y) = \sum_{k=1}^{K} d^{(k)} \Lambda_U(C_k; x, y) \]

and, necessarily, \( \sum_{k=1}^{K} d^{(k)} = 1 \).

Let us note that the functions \( g_j^{(k)} \) considered by Liebscher (2008) and indexed by (I-III) in his Section 2.1 all satisfy the assumptions of Proposition 1. The following result complements Proposition 2.3 in Liebscher (2008) and Proposition 0.1 in Liebscher (2011) which provide bounds on the tail dependence coefficients. Here instead, explicit calculations are provided.
Corollary 1. Let \( \tilde{C} \) be the bivariate copula defined by (1) with \( d = 2 \).

(i) Lower tail, symmetric case. Under the assumptions of Proposition 1(i),

\[
\lambda_L(\tilde{C}) = \prod_{k=1}^{K} \lambda_L(C_k).
\]

(ii) Lower tail, asymmetric case. Under the assumptions of Proposition 1(ii),

\[ \Lambda_L(\tilde{C}) = 0. \]

(iii) Upper tail, general case. Under the assumptions of Proposition 1(iii),

\[
\lambda_U(\tilde{C}) = \sum_{k=1}^{K} \Lambda_U(C_k; d_1^{(k)}, d_2^{(k)})
\]

and, necessarily, \( \sum_{k=1}^{K} d_j^{(k)} = 1 \), for \( j \in \{1, 2\} \).

(iv) Upper tail, particular case. Under the assumptions of Proposition 1(iv),

\[
\lambda_U(\tilde{C}) = \sum_{k=1}^{K} d^{(k)} \lambda_U(C_k)
\]

and, necessarily, \( \sum_{k=1}^{K} d^{(k)} = 1 \).

It appears that the lower and upper tail dependence coefficients have very different behaviors. In the case (i) of a symmetric copulas, the lower tail dependence coefficient \( \lambda_L \) is the product of the lower tail dependence coefficients associated with the components. Besides, \( \lambda_L = 0 \) as soon as a component \( k_0 \) has functions \( g_1^{(k_0)} \) and \( g_2^{(k_0)} \) with different behaviors at the origin (case (ii)). At the opposite, the upper tail dependence coefficient does not vanish even though a component \( k_0 \) has functions \( g_1^{(k_0)} \) and \( g_2^{(k_0)} \) with different behaviors at 1 (case (iii)). In the particular situation where all components \( k \in \{1, \ldots, K\} \) have functions \( g_1^{(k)} \) and \( g_2^{(k)} \) with the same behavior at 1 (case (iv)), \( \lambda_U \) is a convex combination of the upper tail dependence coefficients associated with the components.

2.2 Dependence

Let \((X,Y)\) be a pair of random variables with continuous margins and associated copula \(C\).

- \(X\) and \(Y\) are said to be totally positive of order 2 (TP2, see Joe, 1997) if for all \(x_1 < y_1, x_2 < y_2\),

\[
P(X \leq x_1, Y \leq x_2)P(X \leq y_1, Y \leq y_2) \geq P(X \leq x_1, Y \leq y_2)P(X \leq y_1, Y \leq x_2).
\]

Since this can be equivalently written in terms of \(C\), we will write in short that \(C\) is TP2.

- \(X\) and \(Y\) are said to be positively quadrant dependent (PQD) if

\[
P(X \leq x, Y \leq y) \geq P(X \leq x)P(Y \leq y) \text{ for all } (x, y).
\]
Since this property can be characterized by the copula property $C \geq \Pi$ where $\Pi$ denotes the independence copula, see for instance Nelsen (2007), Paragraph 5.2.1, we shall write for short that $C$ is PQD. The negatively quadrant dependence (NQD) property is similarly defined by $C \leq \Pi$.

- $X$ and $Y$ are said to be left-tail decreasing (LTD) if
  
  \[ F(X \leq x | Y \leq y) \text{ is a decreasing function of } y \text{ for all } x, \text{ and} \]
  \[ F(Y \leq y | X \leq x) \text{ is a decreasing function of } x \text{ for all } y. \]  

  From Nelsen (2007, Theorem 5.2.5), this property can be characterized by the copula properties
  
  \[ C(u,v)/u \text{ is decreasing in } u \text{ for all } v \in [0,1], \]
  \[ C(u,v)/v \text{ is decreasing in } v \text{ for all } u \in [0,1], \]  

  and we shall thus write that $C$ is LTD. The left-tail increasing (LTI) property is similarly defined by reversing the directions of the monotonicity in (3) and (4).

- $X$ and $Y$ are said to be stochastically increasing (SI) if
  
  \[ P(X > x | Y = y) \text{ is an increasing function of } y \text{ for all } x, \text{ and} \]
  \[ P(Y > y | X = x) \text{ is an increasing function of } x \text{ for all } y. \]  

  From Nelsen (2007, Corollary 5.2.11), this property can be characterized by the copula properties
  
  \[ C(u,v) \text{ is a concave function of } u \text{ for all } v \in [0,1], \]
  \[ C(u,v) \text{ is a concave function of } v \text{ for all } u \in [0,1], \]  

  and we shall thus write that $C$ is SI. The stochastically decreasing (SD) property is similarly defined by replacing increasing by decreasing in (5) and concave by convex in (6).

In the next proposition, we show that under mild conditions, the above dependence properties are preserved under Liebscher’s construction, thus complementing LTD and TP$_2$ properties established in Proposition 2.2 of Liebscher (2008).

**Proposition 2.** Let $C_1, \ldots, C_K$ be continuous copulas. If they all satisfy any of the properties defined above, TP$_2$, PQD, NQD, LTD, LTI, SI or SD, then the Liebscher copula $\tilde{C}$ defined in (1) satisfies the same property—for SI (respectively SD), the $g_j^{(k)}$ functions in Theorem 1 are additionally required to be concave functions (respectively convex functions) and the copulas $C_k$ to be twice differentiable, $k \in \{1, \ldots, K\}$, $j \in \{1, \ldots, d\}$.

### 2.3 Stability properties

Let us focus on the situation where the functions $g_j^{(k)}$ of Theorem 1 are power functions. The first result establishes the stability of a family of Liebscher copulas built from homogeneous functions.

**Proposition 3.** For all $j \in \{1, \ldots, d\}$ and $t \in [0,1]$, let $g_j^{(k)}(t) = g_j^{(k)}(t) = t^{p(k)}$ where $p(k) \in (0,1)$ for all $k \in \{1, \ldots, K\}$ and $\sum_{k=1}^{K} p(k) = 1$. Let $m > 0$ and for all $i \in \{1, \ldots, m\}$ introduce

\[ p_k^{(i)} = \sum_{k=1}^{K} p(k) \]
\( \varphi : [0,1]^d \to [0,1] \) such that \( \log \circ \varphi \circ \exp \) is homogeneous of degree \( \lambda_i \). For all \( k \in \{1, \ldots, K\} \), assume that
\[
C_k(u) := C(u \mid \theta_{1k}, \ldots, \theta_{mk}) := \prod_{i=1}^m \varphi_i^{\theta_{ik}}(u), \ u \in [0,1]^d,
\]
is a copula for some \( (\theta_{1k}, \ldots, \theta_{mk}) \in \mathbb{R}^m \). Then, copula (1) is given for all \( K \geq 1 \) by
\[
\tilde{C}^{(K)}(u) := \tilde{C}(u) = C(u \mid \tilde{\theta}_1, \ldots, \tilde{\theta}_m),
\]
with, for all \( i \in \{1, \ldots, m\} \),
\[
\tilde{\theta}_{iK} = \sum_{k=1}^K \theta_{ik}(p^{(k)})^{\lambda_i}.
\]

Example 1 (Gumbel-Barnett copula \( C_k \)). Let \( C_k \) be the (bivariate) Gumbel-Barnett copula (see Nelsen, 2007, Table 4.1). It can be rewritten as
\[
C_k(u,v) = C(u,v \mid \theta_k) = uv \exp(-\theta_k \log(u) \log(v)) = \varphi_1^{\theta_{1k}}(u,v) \varphi_2^{\theta_{2k}}(u,v)
\]
with \( \theta_{1k} = 1, \theta_{2k} = \theta_k \geq 1 \),
\[
\varphi_1(u,v) = uv \text{ and } \varphi_2(u,v) = \exp(-\log(u) \log(v)).
\]
It thus fulfills the assumptions of Proposition 3 with \( d = m = 2, \lambda_1 = 1 \) and \( \lambda_2 = 2 \).

Example 2 (Extreme-value copula \( C_k \)). Recall that a copula \( C_\# \) is said to be max-stable if for all integer \( n \geq 1 \) and \( (u_1, \ldots, u_d) \in [0,1]^d \):
\[
C_\#^n(u_1^{1/n}, \ldots, u_d^{1/n}) = C_\#(u_1, \ldots, u_d).
\]
Extreme-value copulas exactly correspond to max-stable copulas (Gudendorf and Segers, 2010). It is thus clear that every max-stable copula \( C_k \) fulfills the assumptions of Proposition 3 with \( m = 1, \theta_{1k} = 1 \) and \( \lambda_1 = 1 \). Moreover,
\[
\tilde{\theta}_{1K} = \sum_{k=1}^K p^{(k)} = 1
\]
and thus \( \tilde{C}^{(K)} = C \) for all \( K \geq 1 \).

It thus appears that max-stable copulas can be considered as fixed-points of Liebscher’s construction (1). The next result shows that, under mild assumptions, they are the only copulas verifying this property.

Proposition 4. For all \( j \in \{1, \ldots, d\} \) and \( t \in [0,1] \), let \( g_j^{(k)}(t) = g^{(k)}(t) = p^{(k)} \) where \( p^{(k)} \in (0,1) \) for all \( k \in \{1, \ldots, K\} \) and \( \sum_{k=1}^K p^{(k)} = 1 \). Assume \( C_k = C \) for all \( k \in \{1, \ldots, K\} \) and let \( \tilde{C}^{(K)} \) be the copula defined by (1). Then, \( \tilde{C}^{(K)} = C \) for all \( K \geq 1 \) and for all sequences \( p^{(1)}, \ldots, p^{(K)} \in (0,1) \) if and only if \( C \) is max-stable.

To complete the links with max-stable copulas, let us consider the situation where \( C_k = C \) and \( p_j^{(k)} = 1/K \) for all \( j \in \{1, \ldots, d\} \) and \( k \in \{1, \ldots, K\} \). Liebscher’s construction thus yields
\[
\tilde{C}^{(K)}(u) := \tilde{C}(u) = C^K(u_1^{1/K}, \ldots, u_d^{1/K}),
\]
which is the normalized cdf associated with the maximum of \( K \) independent uniform random vectors distributed according to the cdf \( C \). Therefore, as \( K \to \infty \), \( \tilde{C}^{(K)} \) converges to a max-stable copula under standard extreme-value assumptions on \( C \).
2.4 An iterative construction

Let \( \mathcal{F} \) be the class of increasing functions \( f : [0, 1] \rightarrow [0, 1] \) such that \( f(0) = 0, f(1) = 1 \) and \( \text{Id}/f \) is increasing, where \( \text{Id} \) denotes the identity function. For all \( k \geq 1 \) let \( C_k \) be a \( d \)-variate copula and \( f_j^{(k)} \in \mathcal{F} \) for all \( j \in \{1, \ldots, d\} \), with the assumption \( f_j^{(1)}(t) = 1 \) for all \( t \in [0, 1] \). We propose the following iterative construction of copulas. For all \( u \in [0, 1]^d \), consider the sequence defined by

\[
\tilde{C}^{(1)}(u) = C_1(u),
\]

\[
\tilde{C}^{(k)}(u) = C_k \left( \frac{u_1}{f_1^{(k)}(u_1)}, \ldots, \frac{u_d}{f_d^{(k)}(u_d)} \right) \tilde{C}^{(k-1)} \left( f_1^{(k)}(u_1), \ldots, f_d^{(k)}(u_d) \right), \quad k \geq 2.
\]

Lemma 2 in Appendix A.2 shows that \( \tilde{C}^{(k)} \) is a \( d \)-variate copula, for all \( k \geq 1 \).

Let \( K \geq 1 \). For all functions \( f^{(1)}, \ldots, f^{(K)} : [0, 1] \rightarrow [0, 1] \) and \((i, j) \in \{1, \ldots, K\}^2\), let us introduce the notation

\[
\circ_{k=i}^{j} f^{(k)} := f^{(i)} \circ \ldots \circ f^{(j)} \text{ if } i \leq j \text{ and } \circ_{k=i}^{j} f^{(k)} := \text{Id} \text{ otherwise}.
\]

The next result shows that there is a one-to-one correspondence between copulas built by the iterative procedure (7), (8) and Liebscher copulas, reported in Theorem 1.

**Proposition 5.** The copula \( \tilde{C}^{(K)} \), \( K \geq 1 \) defined iteratively by (7), (8) is a Liebscher copula. It can be rewritten as

\[
\tilde{C}^{(K)}(u) = \prod_{k=1}^{K} C_k \left( g_1^{(K-k+1,K)}(u_1), \ldots, g_d^{(K-k+1,K)}(u_d) \right)
\]

for all \( u \in [0, 1]^d \) where, for all \( j \in \{1, \ldots, d\} \) and \( K \geq 1 \),

\[
g_j^{(1,K)} = \text{Id}/f_j^{(K)}
\]

\[
g_j^{(k,K)} = \circ_{i=k+2}^{K} f_j^{(i)} \circ_{i=k+1}^{K} f_j^{(i)}, \quad k \in \{2, \ldots, K\}.
\]

Conversely, each Liebscher copula (defined in Theorem 1) can be built iteratively from (7), (8).

Let us note that the iterative construction (7), (8) thus provides a way to build functions (10), (11) that automatically fulfill Liebscher’s constraints (2) of Theorem 1. As a consequence, the construction (7), (8) also gives an iterative way to sample from a Liebscher copula (1), described in detailed in Algorithm 1 (see the proof Lemma 2 in Appendix A.2 for a theoretical justification).

### Algorithm 1: Iterative sampling scheme for Liebscher copula (1)

**Input** \( \left[ f_j^{(k)} \right]_{k,j}, (C_k)_k \) \( \triangleright \) functions in \( \mathcal{F} \) appearing in (8), and copulas \( (X_1^{(1)}, \ldots, X_d^{(1)}) \sim C_1 \)

for \( k = 2, \ldots, K \) do

\[
(Y_1, \ldots, Y_d) \sim C_k \text{ independently of } (X_1^{(k-1)}, \ldots, X_d^{(k-1)})
\]

for \( j \in \{1, \ldots, d\} \) do

\[
X_j^{(k)} = \max \left( (f_j^{(k)})^{-1}(X_j^{(k-1)}), (\text{Id}/f_j^{(k)})^{-1}(Y_j) \right)
\]

end

**Output** \( X = (X_1^{(K)}, \ldots, X_d^{(K)}) \sim \tilde{C} \)
Example 3 (Power functions $f_j^{(k)}$). Let functions $f_j^{(k)}$ be power functions in the form of

$$f_j^{(k)}(t) = t^{1-a_j^{(k)}}, \quad \text{where } a_j^{(1)} = 1 \text{ and } a_j^{(k)} \in (0, 1) \text{ for all } k \geq 2,$$

for all $j \in \{1, \ldots, d\}$ and $t \in [0, 1]$. From Proposition 5, $g_j^{(k)}(t) = g_j^{(k,K)}(t) = t^{p_j^{(k,K)}}$ with

$$\begin{align*}
p_j^{(1,K)} &= a_j^{(K)}, \\
p_j^{(k,K)} &= a_j^{(K-k+1)} \prod_{i=k-2}^{K} (1 - a_j^{(i)}), \quad \text{if } 2 \leq k \leq K,
\end{align*}$$

for all $K \geq 1$ and $j \in \{1, \ldots, d\}$. Note that, by construction,

$$\sum_{k=1}^{K} p_j^{(k,K)} = 1,$$

for all $j \in \{1, \ldots, d\}$ and thus $\left(p_j^{(1,K)}, \ldots, p_j^{(K,K)}\right)$ can be interpreted as a discrete probability distribution on $\{1, \ldots, K\}$. Besides, let $\tilde{a}_j^{(k,K)} := a_j^{(K+1-k)}$ for all $k \in \{1, \ldots, K\}$. Equations (13) can be rewritten as

$$\begin{align*}
p_j^{(1,K)} &= \tilde{a}_j^{(1,K)}, \\
p_j^{(k,K)} &= \tilde{a}_j^{(k,K)} \prod_{i=1}^{k-1} (1 - \tilde{a}_j^{(i,K)}), \quad \text{if } 2 \leq k \leq K,
\end{align*}$$

which corresponds to the so-called stick-breaking construction (Sethuraman, 1994).

3 The Liebscher–Fréchet copula

We analyze here in more details the Liebscher copula obtained by combining $K \geq 2$ Fréchet copulas defined by $\tilde{C}_L(u, v) = \min(u, v)$. We here focus on the bivariate case $d = 2$, although some of the derivations carry over to the general $d$-dimensional case. We consider the specific case of Example 3, where the functions in Liebscher’s construction are power functions, $g_j^{(k)}(t) = t^{p_j^{(k,K)}}$ with $p_j^{(k,K)} \in [0, 1], j \in \{1, 2\}$ as in (13). Assuming that $K$ is fixed and limiting ourselves to $d = 2$, we denote for notation simplicity $p_k := p_1^{(k,K)}$ and $q_k := p_2^{(k,K)}$ for $k \in \{1, \ldots, K\}$. Recall that, in view of (2), $\sum_{k=1}^{K} p_k = \sum_{k=1}^{K} q_k = 1$. Under the above assumptions, the Liebscher–Fréchet copula denoted by $\tilde{C}_F$ has the form

$$\tilde{C}_F(u, v) = \prod_{k=1}^{K} \min(u^{p_k}, v^{q_k}), \quad (u, v) \in [0, 1]^2.$$

3.1 Geometric description of the Liebscher–Fréchet copula

For all $k \in \{1, \ldots, K\}$, introduce $r_k = p_k/q_k \in [0, \infty]$. For notation simplicity, we shall let $r_0 = 0$ and $r_{K+1} = \infty$. Since the above product (14) is commutative, one can assume without loss of generality that the sequence $(r_k)_{0 \leq k \leq K+1}$ is nondecreasing. The copula $\tilde{C}_F$ can be easily expressed on the partition of the unit square $[0, 1]^2$ defined by the following moon shaped subsets

$$A_k = \{(u, v) \in [0, 1]^2 : u^{r_k+1} < v \leq u^{r_k} \}, \quad \text{for } k \in \{0, \ldots, K\}.$$
Proposition 6. Let $\tilde{C}_F$ be the Liebscher–Fréchet copula defined in (14). Then, for all $(u, v) \in [0, 1]^2$,  
\begin{align*}
\tilde{C}_F(u, v) = \sum_{k=0}^{K} u^{1-p_k} v^{q_k} 1[(u, v) \in A_k],
\end{align*}
where $\bar{x}_k = x_1 + \ldots + x_k$, with the convention that $\bar{x}_0 = 0$.
Moreover, the singular component of $\tilde{C}_F$ is
\begin{align*}
\tilde{S}_F(u, v) = \sum_{k=1}^{K} \min(p_k, q_k) \min(u, v^{1/r_k})^{\max(1, r_k)}.
\end{align*}

The singular component $\tilde{S}_F$ and the absolute continuous component $\tilde{A}_F = \tilde{C}_F - \tilde{S}_F$ weights are $\sum_{k=1}^{K} \min(p_k, q_k)$ and $1 - \sum_{k=1}^{K} \min(p_k, q_k)$, respectively.

A key property of the Liebscher–Fréchet copula (14) is the presence of multiple singular components lying on the curves $v = u^{r_k}$ with associated weights $\min(p_k, q_k)$, $k \in \{1, \ldots, K\}$. Appropriate choices of pairs $(p_k, q_k)_{k=1,...,K}$ may lead to a number of singular components ranging from 0 to $K$. The independence copula (no singular component) is obtained for instance with $p_i = b_j = 1$ for a given pair $(i,j)$, $i \neq j$, the Fréchet copula (one singular component) is obtained by choosing $p_k = q_k, \forall k \in \{1, \ldots, K\}$, and a copula with exactly $K$ singular components can be obtained provided that $0 < r_1 < r_2 < \cdots < r_K < \infty$. See Figure 1 and Figure 2 for illustrations. As a comparison, Cuadras and Augé (1981) copula given by $C(u, v) = (uv)^{1-\theta} \min(u, v)^{\theta}, \theta \in [0, 1]$ is limited to a single singular component, necessarily on the diagonal $v = u$. Similarly, Marshall and Olkin (1967) copula is defined by $C(u, v) = \min(u^{1-\alpha} v, uv^{1-\beta}), (\alpha, \beta) \in [0, 1]^2$ and has only one singular component located on the curve $v = u^{\alpha/\beta}$. The proposal by Lauterbach and Pfeifer (2015) based on singular mixture copulas includes Liebscher–Fréchet copula (14) in the particular case when $K = 2$ but is limited to two singular components. Finally, Sibuya copulas (Hofert and Vrins, 2013) is a very general family of copulas: Let us point out that, in the bivariate case, a non-homogeneous Poisson Sibuya copula allows for only one singular component, this singular component being supported by a curve with very flexible shape (see Remark 4.2 in the previously referenced work for further details).

3.2 Dependence and association properties of Liebscher–Fréchet copula

We consider here several measures of dependence and measures of association between the components of the bivariate Liebscher–Fréchet copula (14). Some of these measures are already dealt with in great generality in Section 2, while some others seem to be tractable only in the Liebscher–Fréchet copula case: Blomqvist’s medial correlation coefficient, Kendall’s $\tau$ and Spearman’s $\rho$.

Tail dependence. Recall that for the Fréchet copula $C_F$, it holds $\Lambda_u(C_F; \cdot, \cdot) = \min(\cdot, \cdot)$. Then, Corollary 1 yields
\begin{align*}
\lambda_L(\tilde{C}_F) = \prod_{k=1}^{K} 1(p_k = q_k), \quad \text{and} \quad \lambda_U(\tilde{C}_F) = \sum_{k=1}^{K} \min(p_k, q_k).
\end{align*}
In other words, the lower tail dependence coefficient is non zero only in the case when $p_k = q_k$ for all $k \in \{1, \ldots, K\}$, where $\tilde{C}_F$ boils down to the Fréchet copula, while the upper tail dependence coefficient coincides with the weight of the singular component $\tilde{S}_F$ (see Proposition 6).
Figure 1: Top-left: representation of the $p \times q$ square unit space. Other five panels: scatter plots of $n = 10^4$ data points sampled from Liebscher–Fréchet copula with $K = 2$. Choices for parameters $(p,q)$ (such that $p_1 = p$, $p_2 = 1 - p$, $q_1 = q$, $q_2 = 1 - q$) are summarized on the top-left panel. Complete dependence (top-middle), complete independence (top-right), symmetric (bottom-left), asymmetric (bottom-middle), degenerate asymmetric (bottom-right).

**Dependence.** It is well-known that the Fréchet copula $C_F$ fulfills the following positive dependence properties defined in Section 2.2, namely it is TP$_2$, PQD, LTD and SI (Nelsen, 2007). According to Proposition 2, we can thus conclude that the Liebscher–Fréchet copula $C_F$ also satisfies these positive dependence properties.

**Stability properties.** It is easily seen that Liebscher–Fréchet copula (14) is max-stable. Proposition 4 thus entails that this copula is stable with respect to Liebscher’s construction. Another consequence is that Liebscher–Fréchet construction (14) can be interpreted as a possible cdf for modelling bivariate maxima.

**Dependence coefficients.** The β-Blomqvist’s medial correlation coefficient (Nelsen, 2007, Paragraph 5.1.4) defined by $\beta(C) = 4C\left(\frac{1}{2}, \frac{1}{2}\right) - 1$, Kendall’s $\tau$ (Nelsen, 2007, Paragraph 5.1.1) and Spearman’s $\rho$ (Nelsen, 2007, Paragraph 5.1.2) defined by

\[
\tau(C) = \frac{4}{3} \int_{[0,1]^2} C(u,v) \, dC(u,v) - 1,
\]

\[
\rho(C) = 12 \int_{[0,1]^2} C(u,v) \, du \, dv - 3
\]

are provided in next proposition.
Figure 2: Scatter plots of $n = 10^4$ data points sampled from Liebscher–Fréchet copula with $K > 2$. Top-left: $K = 3$, $r_k \in \{0, 1, \infty\}$; Top-middle: $K = 3$, $r_k \in \{0.3, 1, \infty\}$; Top-right: $K = 4$, $r_k \in \{0, 0.7, 0.9, 1.7\}$; Bottom-left: $K = 4$, $r_k \in \{0.3, 1.9, 8.3, 8.3\}$; Bottom-middle: $K = 5$, $r_k \in \{0.6, 0.9, 1.1, 1.4, 3.6\}$; Bottom-right: $K = 6$, $r_k \in \{0.04, 0.3, 2.8, 3.3, 4.2, 5.8\}$.

Proposition 7. Blomqvist’s medial correlation coefficient, Kendall’s $\tau$ and Spearman’s $\rho$ for the Liebscher–Fréchet copula (14) are respectively given by

\[
\beta(\hat{C}_\nu) = 2\sum_{k=1}^{K-1} \min(p_k, q_k) - 1,
\]

\[
\tau(\hat{C}_\nu) = 1 - \sum_{k=1}^{K-1} \frac{(1 - \bar{p}_k)(r_{k+1} - r_k)}{(\bar{q}_k r_k + (1 - \bar{p}_k))(\bar{q}_k r_{k+1} + (1 - \bar{p}_k))},
\]

\[
\rho(\hat{C}_\nu) = \frac{12(1 + r_1 + r_1 r_K)}{(2 + r_1)(1 + 2r_K)} - 3 + \sum_{k=1}^{K-1} \frac{r_{k+1} - r_k}{((1 + q_k)r_k + (2 - \bar{p}_k))(1 + q_k)r_{k+1} + (2 - \bar{p}_k))},
\]

where $x_k = x_1 + \ldots + x_k$.

It appears that $\beta$-Blomqvist medial correlation coefficient is closely related to the upper tail dependence coefficient: $\beta(\hat{C}_\nu) = 2^{\lambda_U(\hat{C}_\nu)} - 1$. Besides, in the particular case where $K = 2$, the Kendall’s $\tau$ can be simplified as $\tau(\hat{C}_\nu) = p_1 + q_2 = \lambda_U(\hat{C}_\nu)$. No similar simplification seems to be possible for Spearman’s $\rho$.

3.3 Iterative construction for Liebscher–Fréchet copula

Algorithm 1 can be simplified when specified to Liebscher–Fréchet setting since: (i) sampling from the Fréchet copula is straightforward and only requires sampling from the uniform distribution
\(\mathcal{U}(0,1)\), and (ii) power functions benefit from an explicit inverse. The specific sampling procedure for this construction is described in detail as Algorithm 2.

### Algorithm 2: Iterative sampling scheme for Liebscher–Fréchet copula (14)

**Input**

\[ a^{(k)}_j \]

\( (k,j) \)

> exponents of power functions \( f^{(k)}_j \)

**Output**

\[ X = (X^{(K)}_1, \ldots, X^{(K)}_d) \sim \tilde{C}_F \]

\[ X^{(1)}_j \sim \mathcal{U}(0,1) \text{ for each } j = 1, \ldots, d \]

for \( k = 2, \ldots, K \) do

Sample \( Y \sim \mathcal{U}(0,1) \), independently of \( X^{(k-1)}_1, \ldots, X^{(k-1)}_d \)

for \( j \in \{1, \ldots, d\} \) do

Compute

\[
X^{(k)}_j = \max \left( X^{(k-1)}_j \left( \frac{1}{1-a^{(k)}_j} - \frac{1}{Y} \right) , Y^{-a^{(k)}_j} \right)
\]

end

end

4 Bayesian inference

In this section, we provide a simple strategy to make Bayesian inference on any Liebscher copula based on an Approximate Bayesian computation algorithm (ABC, see for instance Marin et al., 2012, Robert, 2018, Karabatsos and Leisen, 2018, for reviews). ABC is a “likelihood-free” method usually employed for inference of models with intractable likelihood: it enables to perform approximate Bayesian analysis on any statistical model from which it is possible to sample new data, without the need to explicitly evaluate the likelihood function.

| 1. Sample \( \theta \) from the prior distribution \( \pi(\theta) \); |
| 2. Given \( \theta \), sample \( X_1, \ldots, X_n \) from \( L_\theta \), and set \( X = \{X_1, \ldots, X_n\} \); |
| 3. If \( X \) is too different from \( X_{\text{obs}} \), discard \( \theta \), otherwise, keep \( \theta \). |

The outcome of the ABC algorithm is a sample of values of the parameter \( \theta \) approximately distributed according to its posterior distribution. The basic (rejection) ABC approach in point 3. amounts to \text{a priori} specifying a tolerance level \( \epsilon > 0 \), and then keeping \( \theta \) if \( d(X, X_{\text{obs}}) < \epsilon \) for some distance \( d(\cdot, \cdot) \) between samples. Another common approach employed in this paper consists in selecting the tolerance level \( \epsilon \) as a fixed quantile of the distances \( d(X, X_{\text{obs}}) \). More specifically, steps 1. to 3. are repeated \( M' \) times, out of which \( M \) are retained, yielding a quantile of order \( M/M' \) (Robert, 2018). In this paper, we choose as distance between samples the Hilbert distance introduced in Bernton et al. (2017), henceforth denoted by \( d_H(\cdot, \cdot) \). The Hilbert distance is an approximation of the Wasserstein distance between empirical probability distributions which preserves the desirable properties of the latter in the context of ABC, while being considerably faster to compute in multivariate data settings (see Bernton et al., 2017, for details).
The choice for ABC is motivated by two main reasons. First, it is nontrivial in general to derive the likelihood of copulas, especially for Liebscher copulas which involve differentiating a product of \( K \) terms. All the more, the specific case of Liebscher–Fréchet copulas induces up to \( K \) singular components which precludes a general evaluation of the likelihood. Second, sampling new data (step 2. above) from a Liebscher copula is straightforward and fast thanks to the iterative procedure of Algorithm 1 (Section 2.2).

Section 4.1 introduces the ABC procedure in the case of the Liebscher copula (1) and describes the prior distributions on the model parameters. The methodology is then illustrated on two data generating distributions: Section 4.2.1 focuses on the well-specified setting where the data are sampled from the Liebscher–Fréchet copula; we show that the estimation procedure performs well in this case. Then, Section 4.2.2 investigates the misspecified setting where the data are sampled from a noisy version of the model; we show that the estimation procedure still performs well, but the estimation accuracy may deteriorate for too large values of the noise.

4.1 ABC inference for Liebscher copulas

The description of the ABC procedure is first completed by specifying the prior distributions on the model parameters. For simplicity, we here focus on the case of the \( d \)-dimensional Liebscher copula with the functions \( f_j^{(k)}(\cdot) \), \( k \in \{1, \ldots, K\} \), \( j \in \{1, \ldots, d\} \) of Algorithm 1 chosen as the power functions (12) introduced in Example 3. The parameters of the \( f_j^{(k)}(\cdot) \) functions are collected in a \( K \times d \) matrix \( A = \{a_j^{(k)}\}_{k,j} \), where \( a^{(1)} = (a_1^{(1)}, \ldots, a_d^{(1)}) = (1, \ldots, 1) \). Since the \((K-1)d\) free parameters are constrained to \( a_j^{(k)} \in (0, 1) \) for \( 2 \leq k \leq K \), we simply choose, by symmetry, independent and uniform distributions \( a_j^{(k)} \text{ iid } \sim U(0, 1) \). More flexible distributions like the Beta distribution could be thought of in order to reflect some prior knowledge on these parameters. Additionally, note that different functions \( f_j^{(k)}(\cdot) \) would simply require setting prior distributions adapted to the parameters used.

The number of iterative steps \( K \) is also considered as a parameter of the model. Independently of parameters \( A, K \) is assigned a Zipf distribution, \( K \sim \text{Zipf}(\xi) + 1 \), for \( \xi > 1 \). Such a distribution is supported on integers \( k \geq 2 \) and has probability mass function \( P(K = k) \) proportional to \((k-1)^{-\xi}\). We further choose the parameter \( \xi \) to be equal to 2, which insures that 90% of the prior mass for \( K \) is supported on most realistic values \( 2 \leq K \leq 6 \). This can be changed depending on applications at hand. Another option, useful in case where some prior information is available on \( K \), is to adopt a Binomial distribution (translated, such that \( K \geq 2 \)). The choice of the two hyper-parameters of the Binomial density could then be set as a function of prior knowledge, such as prior mode and confidence, that one may be able to elicit based on expert knowledge or previous studies.

We are now ready to state the main ABC inference procedure as Algorithm 3.

In general, the sequence of copulas \((C_k)_k\) depends on some sequence of parameters \((\gamma_k)_k\). In such a case, Algorithm 3 can be easily amended by adding a step consisting in sampling \( \gamma_k \) parameters from some prior distribution to be set based on available prior information or expert knowledge. In the following section, we focus on the case of Liebscher–Fréchet copulas, which do not depend on any additional parameter. Thus, the sampling step for new data \( X \) in Algorithm 3 is performed with the iterative construction of Algorithm 2 tailored to Liebscher–Fréchet copulas.
Algorithm 3: ABC inference for Liebscher copulas

Input \( X_{\text{obs}}, M', M, (C_k)_k \)

for \( s = 1, \ldots, M' \) do

\[ K \sim \text{Zipf}(\xi) + 1 \quad \triangleright \text{sample number of iterations in construction (1)} \]

for \( j \in \{1, \ldots, d\} \) and \( k \in \{1, \ldots, K\} \) do

\[ a^{(1)}_j = 1 \]

\[ a^{(k)}_j \sim \mathcal{U}(0, 1) \quad \triangleright \text{sample copula parameters} \]

end

\( X_1, \ldots, X_n \sim \tilde{C}_K \quad \triangleright \text{sample data using Algo. 1 with power functions and } A = [a^{(k)}_j]_{j,k} \)

\( X = \{X_1, \ldots, X_n\} \quad \triangleright \text{set synthetic data} \)

\( d^2_H = d_H(X_{\text{obs}}, X) \quad \triangleright \text{compute Hilbert distances} \)

end

Output \( (X_m, A_m, K_m)_{m=1,\ldots,M} \quad \triangleright \text{choose } M \text{ parameters with smallest } d^2_H \)

4.2 Numerical illustrations

This section provides two illustrations of the inferential procedures described so far. The first investigates a setting where data are sampled from the Liebscher–Fréchet model, while the second is concerned with observations from a noisy version of it. The code, implemented in R also using the \textit{copula} package (Yan, 2007), is available at the following link: https://sites.google.com/site/crispinostat/research?authuser=0.

4.2.1 Well-specified setting: data from Liebscher–Fréchet copula

We generate \( n = 500 \) data points from a 2-dimensional Liebscher–Fréchet copula (14) with \( d = 2 \), varying values of \( K \geq 2 \) and of the parameters in the matrix \( A \), using Algorithm 2. The estimation is then performed with the ABC procedure summarized in Algorithm 3.

Our method provides the full (approximate) posterior distribution of the parameters of interest, making possible to select any strategy to summarize them, possibly driven by the application at hand. One can for instance compute the posterior distribution of the Spearman’s \( \rho \), and, thanks to the retained samples, any other quantity of interest. Here, the performance of the estimation procedure is assessed basing on the following three summary statistics: (i) Kendall’s distribution function \( K(t) = \mathbb{P}_C(C(U, V) < t) \), (ii) Spearman’s \( \rho \) index of association, introduced in Section 3.2, and for which an explicit closed form is obtained for Liebscher–Fréchet copula in Proposition 7, and (iii) an asymmetry measure, since it is a central motivation of the present work. More specifically, the Cramér-von Mises test statistics \( E_C[(C(U, V) - C(V, U))^2] \) defined in Genest et al. (2012) has been selected since it emerged as a powerful statistic to test the symmetry of a copula. Following the strategy of Genest et al. (2012), the approximate p-values associated with the symmetry test, performed both on the observed sample \( X_{\text{obs}} \) and on the retained samples \( X_m, m \in \{1, \ldots, M\} \), are computed on the basis of 250 bootstrap replicates.

The results obtained on a single simulation experiment are displayed on Figure 3, where \( n = 500 \) data points were simulated from the Liebscher–Fréchet copula (14) with \( d = 2 \) and \( K = 3 \) (top-left panel). The number of ABC iterations was set to \( M' = 10^4 \), of which \( M = 300 \) were retained (resulting in a quantile of order 3%). The empirical Kendall’s distribution functions of the observed and retained samples are compared on the top-right panel; The posterior distribution of \( \rho \) is
Figure 3: Results from a simulation experiment. Top-left: \( n = 500 \) data points simulated from a Liebscher–Fréchet copula with \( d = 2, K = 3 \) and \( r_k \in \{0.26, 0.44, 17.32\} \). Top-right: empirical Kendall’s distribution function \( \hat{K} \) of the observed (black) and retained (gray) samples; Bottom-left: boxplot of the posterior distribution of \( \rho \) (the dashed line corresponds to the empirical Spearman’s \( \rho \) of the observed sample); Bottom-right: boxplot of the posterior distribution of the approximate p-values (the dashed line corresponds to \( X_{\text{obs}} \), and the dotted line is the 5\% threshold).

compared to the empirical Spearman’s \( \rho \) of the observed sample on the bottom-left panel; Finally, the posterior distribution of the approximate p-values is displayed on the bottom-right panel. Let us highlight that the estimating procedure provides distributions around the true values in the three considered cases.

We then vary the generating number of iterative steps \( K \) and compute the average relative errors \( \eta_C \) and \( \eta_P \) for \( K \) and \( \rho \) between the values computed on the observed sample and on the \( M \) samples retained by ABC:

\[
\eta_C = \frac{1}{M} \sum_{m=1}^{M} \frac{\| \hat{K}_{\text{obs}} - \hat{K}_m \|_1}{\| \hat{K}_{\text{obs}} \|_1}, \quad \text{and} \quad \eta_P = \frac{1}{M} \sum_{m=1}^{M} \frac{|\hat{\rho}_{\text{obs}} - \hat{\rho}_m|}{|\hat{\rho}_{\text{obs}}|},
\]

(17)

where \( \| \cdot \|_1 \) denotes the \( l_1 \)-norm. In order to take care of the randomness involved in sampling the parameters in the matrix \( A \), the previous procedure has been replicated 20 times based on 20
independent data samples repetitions. The average relative errors $\eta_K$ and $\eta_\rho$ in (17) were therefore averaged over the 20 independent samples, and reported as $\bar{\eta}_K$ and $\bar{\eta}_\rho$ in Table 1 (first two rows), along with standard deviations in parentheses. As for the asymmetry test, we computed for each of the 20 data replications the fraction of times (out of $M$) that the same decision is taken (‘reject’ vs ‘do not reject’) at the 5% level, based on the approximate p-values computed on $X_m$ and $X_{\text{obs}}$. The obtained values were averaged over the 20 independent data samples repetitions and reported in the third row of Table 1 as $\bar{f}_{\text{test}}$.

<table>
<thead>
<tr>
<th>$K$</th>

<td>13.3 (18.1)</td>
</tr>
</tbody>
</table>

Table 1: First two rows: average relative errors (17) for Kendall’s distribution function and Spearman’s $\rho$ between the observed sample and the samples retained by the ABC procedure, for varying $K$ (columns). Third row: fraction of times that the same decision is taken (‘reject’ vs ‘do not reject’, at the 5% level) based on $X_m$ and $X_{\text{obs}}$. The results are averaged over 20 independent repetitions. Standard deviations in parentheses. All values are in %.

Table 1 suggests a general trend: the larger $K$ is, the more difficult the estimation is. However, the estimation procedure yields satisfactory results for all cases considered.

### 4.2.2 Misspecified setting: data from a noisy Liebscher–Fréchet copula

In this section, we generate data from a noisy version of the Liebscher–Fréchet copula, and demonstrate that our inference procedure works well even if the data are not sampled from the exact model (so-called misspecified setting). In order to sample data from such a noisy model, a slightly changed version of Algorithm 2 is used in which the parameters $A$ are not fixed. Instead, they are sampled from a beta distribution with given variance $\sigma_a^2$ (interpreted as the error variance) around some fixed value corresponding to the zero noise version. The latter is illustrated on Figure 4: a sample of $n = 10^3$ data points from a 2-dimensional Liebscher–Fréchet copula is depicted on the top-left panel with $K = 2$ iterative steps, and with the two parameters of the power functions set to $a_1^{(2)} = 0.4$ and $a_2^{(2)} = 0.8$ (recall that $a_1^{(1)} = a_2^{(1)} = 1$). The remaining five panels correspond to samples from Liebscher–Fréchet copula with increasing noise variance $\sigma_a^2 = 10^{-5}, 10^{-4}, 10^{-3}, 10^{-2}, 10^{-1}$.

The inference results obtained from Algorithm 3 (ran with $M' = 10^4$ ABC iterations of which $M = 300$ were retained) are reported in Table 2. Unsurprisingly, it appears that the larger the noise variance is, the more difficult is the estimation. Again, the estimation procedure yields good results for all cases considered. Let us note that the results reported in Table 2 are not averaged over 20 independent replications like in the previous section. The reason is that, here, the interest is in illustrating how the procedure deteriorates with the increasing noise in the observed data. Therefore, it is sufficient to illustrate the results of the analysis on a single dataset.
Figure 4: Samples from the exact Liebscher–Fréchet copula with $d = K = 2$, $a_1^{(2)} = 0.4$, $a_2^{(2)} = 0.8$ (top-left panel) and from five noisy versions of it, where, for each data point $i \in \{1, \ldots, n\}$, $a_{i1}^{(2)} \sim \text{Be}(\alpha_1, \beta_1)$ and $a_{i2}^{(2)} \sim \text{Be}(\alpha_2, \beta_2)$ such that $\mathbb{E}(a_{i1}^{(2)}) = 0.4$, $\mathbb{E}(a_{i2}^{(2)}) = 0.8$, and increasing noise variance $\sigma_n^2 = \mathbb{V}(a_{i1}^{(2)}) = \mathbb{V}(a_{i2}^{(2)}) = 10^{-5}, 10^{-4}, 10^{-3}, 10^{-2}, 10^{-1}$ (other panels). Sample size $n = 10^3$.

Table 2: First two rows: average relative errors (17) for Kendall’s distribution function and Spearman’s $\rho$ between the observed sample and the samples retained by the ABC procedure, for growing noise (columns). Third row: fraction of times that the same decision is taken at the 5% level based on $X_m$ and $X_{obs}$. All values are in %.

5 Conclusion

In this paper, we have studied the class of asymmetric copulas first introduced by Khoudraji (1995), and developed in its general form by Liebscher (2008). Some new theoretical properties of these copulas were proved, including novel closed form expressions for its tail dependence coefficients, thus complementing the partial results of Liebscher (2008) and Liebscher (2011). An iterative procedure is also introduced to flexibly sample from these copulas, which makes it easy to apply an Approximate Bayesian computation procedure to make inference on them.

A Appendix: Proofs

A.1 Proofs of main results

**Proof of Proposition 1.** (i) Recall that \( d = 2 \) and introduce \( g^{(k)} := g_1^{(k)} = g_2^{(k)} \) for all \( k \in \{1, \ldots, K\} \). For all \( x > 0 \), we have

\[
x = \frac{\epsilon x}{\epsilon} \rightarrow_0 \prod_{k=1}^{K} \frac{g^{(k)}(\epsilon x)}{g^{(k)}(\epsilon)} \prod_{k=1}^{K} x^{\gamma^{(k)}} = x \sum_{k=1}^{K} \gamma^{(k)},
\]

since the product of the \( g^{(k)} \) functions is the identity (a) and by definition of regular variation (b). It follows that \( \sum_{k=1}^{K} \gamma^{(k)} = 1 \). Besides,

\[
\tilde{C}(\epsilon x, \epsilon y) = \frac{\prod_{k=1}^{K} C_k(g^{(k)}(\epsilon x), g^{(k)}(\epsilon y))}{\prod_{k=1}^{K} g^{(k)}(\epsilon)} = \frac{\prod_{k=1}^{K} C_k(g^{(k)}(\epsilon) x^{\gamma^{(k)}}, g^{(k)}(\epsilon) y^{\gamma^{(k)}}) + o(g^{(k)}(\epsilon))}{\prod_{k=1}^{K} g^{(k)}(\epsilon)} \rightarrow_0 \prod_{k=1}^{K} \Lambda_L(C_k; x^{\gamma^{(k)}}, y^{\gamma^{(k)})},
\]

by the regular variation property (a), by Lipschitz property for copulas and because of the continuity of \( g^{(k)} \) at the origin (c). The result is thus proved.

(ii) Let \( x \leq y \), the proof being similar when \( x > y \). We have

\[
\tilde{C}(\epsilon x, \epsilon y) = \prod_{k=1}^{K} C_k(g^{(k)}(\epsilon x), g^{(k)}(\epsilon y)) \leq \prod_{k=1}^{K} \min(g^{(k)}(\epsilon x), g^{(k)}(\epsilon y)),
\]

since, for any copula \( C \) and any \((u, v) \in [0, 1]^2\), \( C(u, v) \leq \min(u, v) \). By assumption here, there exists \( k_0 \in \{1, \ldots, K\} \) such that \( \eta(t) := g^{(k_0)}(t)/g^{(k_0)}(t) \), where \( \eta(t) \to 0 \) as \( t \to 0 \). Taking into account that \( g^{(k_0)} \) is increasing, this entails

\[
\prod_{k=1}^{K} \min(g^{(1)}(\epsilon x), g^{(2)}(\epsilon y)) \leq g^{(k_0)}(\epsilon x) \prod_{k \neq k_0} g^{(k)}(\epsilon y) \leq g^{(k_0)}(\epsilon y) \prod_{k \neq k_0} g^{(k)}(\epsilon y) = \eta(\epsilon y) \prod_{k=1}^{K} g^{(k)}(\epsilon y).
\]

Recalling that \( \prod_{k=1}^{K} g^{(k)}(\epsilon) \) is the identity function, it follows that

\[
\tilde{C}(\epsilon x, \epsilon y) \leq \eta(\epsilon y) \epsilon y,
\]

and consequently \( \Lambda_L(\tilde{C}; x, y) = 0 \).

(iii) Differentiating the product of the \( g^{(k)} \) functions, we obtain for \( j \in \{1, 2\} \):

\[
1 = \sum_{k=1}^{K} (g^{(k)})'(u) \prod_{\ell \neq k} g^{(\ell)}(u).
\]

Now, since \( g^{(\ell)}(1) = 1 \) for all \( \ell \in \{1, \ldots, K\} \), and \( j = 1, 2 \), we obtain \( \sum_{k=1}^{K} d^{(k)}_j = 1 \). Turning to the upper dependence function, let us write

\[
\tilde{C}(1 - \epsilon x, 1 - \epsilon y) - 1 \sim_0 - \log \tilde{C}(1 - \epsilon x, 1 - \epsilon y) = - \sum_{k=1}^{K} \log C_k(g^{(1)}(1 - \epsilon x), g^{(2)}(1 - \epsilon y)).
\]
By assumption, all $g_j^{(k)}$ are differentiable at 1, with derivative denoted by $d_j^{(k)}$, and satisfy $d_j^{(k)}(1) = 1$. Hence, the first order Taylor expansion is $g_j^{(k)}(1-\varepsilon) = 1 - d_j^{(k)} \varepsilon + o(\varepsilon)$. By the Lipschitz property of copulas,

$$C_k(g_1^{(k)}(1-\varepsilon), g_2^{(k)}(1-\varepsilon)) = C_k(1 - d_1^{(k)} \varepsilon x + o(\varepsilon), 1 - d_2^{(k)} \varepsilon y + o(\varepsilon)) = C_k(1 - d_1^{(k)} \varepsilon x, 1 - d_2^{(k)} \varepsilon y) + o(\varepsilon).$$

Plugging in to (18) yields

$$\frac{\tilde{C}(1 - \varepsilon x, 1 - \varepsilon y) - 1}{\varepsilon} \sim -\frac{1}{\varepsilon} \sum_{k=1}^{K} \log \left( C_k(1 - d_1^{(k)} \varepsilon x, 1 - d_2^{(k)} \varepsilon y) + o(\varepsilon) \right) \sim \sum_{k=1}^{K} C_k(1 - d_1^{(k)} \varepsilon x, 1 - d_2^{(k)} \varepsilon y) - 1 + o(1).$$

Finally, in view of $\sum_{k=1}^{K} d_j^{(k)} = 1$ for $j = 1, 2$ it follows that

$$x + y + \frac{\tilde{C}(1 - \varepsilon x, 1 - \varepsilon y) - 1}{\varepsilon} \sim \sum_{k=1}^{K} \left( d_1^{(k)} x + d_2^{(k)} y + \frac{C_k(1 - d_1^{(k)} \varepsilon x, 1 - d_2^{(k)} \varepsilon y) - 1}{\varepsilon} \right) + o(1).$$

Taking the limit $\varepsilon \to 0$ yields the result:

$$\Lambda_U(\tilde{C}; x, y) = \sum_{k=1}^{K} \Lambda_U(C_k; d_1^{(k)} x, d_2^{(k)} y).$$

(iv) The case $d_1^{(k)} = d_2^{(k)}$ for all $k \in \{1, \ldots, K\}$ is then a simple consequence of the homogeneity property of the upper tail dependence function.  

**Proof of Corollary 1.** This is a direct consequence of Proposition 1.  

**Proof of Proposition 2.** Liebscher (2008, Proposition 2.2) proves the TP and LTD properties. The LTI property can be proven in the same way as LTD. For PQD, it suffices to remark that for any $u, v \in [0, 1]$,

$$\tilde{C}(u, v) = \prod_{k=1}^{K} C_k(g_1^{(k)}(u), g_2^{(k)}(v)) \geq \prod_{k=1}^{K} g_1^{(k)}(u) g_2^{(k)}(v) = \prod_{k=1}^{K} g^{(k)}(u) \prod_{k=1}^{K} g^{(k)}(v) = uv,$$

while NQD works similarly with a reversed inequality in (a).

Let us prove the SI part. According to Equation (6), SI is a property of $u \mapsto \tilde{C}(u, v)$ and $v \mapsto \tilde{C}(u, v)$ functions. Focusing w.l.o.g. on the former function, and omitting the $v$ variable for notational simplicity, $\tilde{C}$ can be written as

$$\tilde{C}(u) = C_1(g^{(1)}(u)) \ldots C_K(g^{(K)}(u)),$$

with $g^{(1)}(u) \ldots g^{(K)}(u) = u$ for all $u \in [0, 1]$. Differentiating this function twice yields $\tilde{C}''(u) = (T_1(u) + T_2(u))\tilde{C}(u)$ where

$$T_1 = \sum_{k=1}^{K} (g^{(k)})'' \frac{C''(g^{(k)})}{C_k(g^{(k)})}, \quad T_2 = \sum_{k=1}^{K} \tau_k \frac{C''(g^{(k)})}{C_k(g^{(k)})},$$

with $\tau_k = g^{(k)''} + g^{(k)} \sum_{\ell \neq k} (g^{(\ell)})'' \frac{C''(g^{(\ell)})}{C_k(g^{(\ell)})}$.
By assumption, $C_1, \ldots, C_K$ are SI, hence they are concave, thus $C^{''}_i \leq 0$, ..., $C^{''}_K \leq 0$ and therefore $T_1 \leq 0$. In view of Theorem 5.2.12 and Corollary 5.2.6 in Nelsen (2007), $u \mapsto C'_j(u) - C_i(u)/u$ is a negative function for all $\ell \in \{1, \ldots, K\}$. As a consequence, $\tau_k$ can be upper bounded as follows:

$$\tau_k \leq g^{(k)''} + g^{(k)'} \sum_{\ell \neq k} \frac{g^{(\ell)}(u)}{g^{(\ell)}(u)} = g^{(k)''} + g^{(k)'} \left( \frac{1}{\text{Id}} - \frac{g^{(\ell)′}}{g^{(\ell)'}} \right),$$

(19)

where (a) is due to the fact that the product of all $g^{(\ell)}(u)$ functions is the identity $\text{Id}$. Additionally, since $g^{(k)}$ is concave and $g^{(k)}(0) = 0$, Theorem 5 by Bruckner and Ostrow (1962) implies that $-g^{(k)}$ is star-shaped i.e. $-g^{(k)}/\text{Id}$ is increasing. This, in turn, proves that the right-hand side of (19) can be further upper bounded by zero, and therefore $T_2 \leq 0$. As a conclusion, $\tilde{C}'' < 0$ and, in virtue of Equation (6), $\tilde{C}$ is also SI. The proof for SD follows similar lines.

**Proof of Proposition 3.** By definition of the copula $\tilde{C}$,

$$\log \tilde{C}(\mathbf{u}) = \sum_{k=1}^{K} \log C_k \left( g^{(k)}_1(u_1), \ldots, g^{(k)}_d(u_d) \right)$$

$$= \sum_{k=1}^{K} \sum_{i=1}^{m} \theta_{ik} \log \varphi_i \left( u^{p^{(k)}}_1, \ldots, u^{p^{(k)}}_d \right)$$

$$= \sum_{k=1}^{K} \sum_{i=1}^{m} \theta_{ik} \left( \log \circ \varphi_i \circ \exp \right) \left( p^{(k)} \log u_1, \ldots, p^{(k)} \log u_d \right)$$

$$= \sum_{k=1}^{K} \sum_{i=1}^{m} \theta_{ik} \left( p^{(k)} \right)^\lambda_i \left( \log \circ \varphi_i \circ \exp \right) \left( \log u_1, \ldots, \log u_d \right)$$

$$= \sum_{k=1}^{K} \sum_{i=1}^{m} \theta_{ik} \left( p^{(k)} \right)^\lambda_i \log \varphi_i \left( \mathbf{u} \right)$$

$$= \sum_{i=1}^{m} \sum_{k=1}^{K} \theta_{ik} \left( p^{(k)} \right)^\lambda_i \log \varphi_i \left( \mathbf{u} \right)$$

$$= \sum_{i=1}^{m} \tilde{\theta}_i \log \varphi_i \left( \mathbf{u} \right)$$

$$= \log C(\mathbf{u} | \tilde{\theta}_1 K, \ldots, \tilde{\theta}_m K),$$

and the result is proved.

**Proof of Proposition 4.** Let us remark that Example 2 shows that $C$ is max-stable implies $\tilde{C}(K) = C$ for all $K \geq 1$ and for all sequence $(p^{(k)})_k \subset (0, 1)$. Conversely, assume that $\tilde{C}(K) = C$ for all $K \geq 1$ and for all sequence $(p^{(k)})_k \subset (0, 1)$. From (1) with $K = 2$, it follows that

$$C(\mathbf{u}) = C \left( u^{p^{(1)}}_1, \ldots, u^{p^{(1)}}_d \right) C \left( u^{1-p^{(1)}}_1, \ldots, u^{1-p^{(1)}}_d \right),$$

for all $\mathbf{u} \in [0, 1]^d$. Introducing $\varphi : \mathbb{R}_-^d \to \mathbb{R}_-$ the continuous function defined by $\varphi = \log \circ C \circ \exp$, we thus have

$$\varphi(\mathbf{u}) = \varphi(p^{(1)} \mathbf{u}) + \varphi((1 - p^{(1)}) \mathbf{u}),$$

24
for all $u \in [0,1]^d$ and $p^{(1)} \in (0,1)$. Lemma 1 in Appendix A.2 entails that $\varphi$ is homogeneous of degree 1 or equivalently that $C$ is max-stable.

**Proof of Proposition 5.** Let us first show that the copula $\tilde{C}^{(K)}$, $K \geq 1$ defined iteratively by (7), (8) is a Liebscher copula. The proof is done by induction on $K$. First, it is clear that

$$\tilde{C}^{(1)}(u) = C_1 \left( g_1^{(1,1)}(u_1), \ldots, g_d^{(1,1)}(u_d) \right) = C_1 \left( u_1/f^{(1)}(u_1), \ldots, u_d/f^{(1)}(u_d) \right)$$

$$= C_1(u).$$

Second, assume that

$$\tilde{C}^{(K-1)}(u) = \prod_{k=1}^{K-1} C_k \left( g_1^{(K-k,K-1)}(u_1), \ldots, g_d^{(K-k,K-1)}(u_d) \right)$$

and

$$g_j^{(K-1)}(u) = \frac{\text{Id}}{f_j^{(K-1)}}$$

$$g_j^{(K-1)} = \prod_{i=K-k-1}^{K-1} f_{j_i}^{(i)}$$

From (8), it follows that

$$\tilde{C}^{(K)}(u) = C_K \left( \frac{u_1}{f_1^{(K)}(u_1)}, \ldots, \frac{u_d}{f_d^{(K)}(u_d)} \right) \tilde{C}^{(K-1)} \left( f_1^{(K)}(u_1), \ldots, f_d^{(K)}(u_d) \right)$$

$$= C_K \left( \frac{u_1}{f_1^{(K)}(u_1)}, \ldots, \frac{u_d}{f_d^{(K)}(u_d)} \right)$$

$$\times \prod_{k=1}^{K-1} C_k \left( g_1^{(K-k,K-1)}(u_1), \ldots, g_d^{(K-k,K-1)} \circ f_{d}^{(K)}(u_d) \right)$$

$$= \prod_{k=1}^{K} C_k \left( g_1^{(K-k+1,K)}(u_1), \ldots, g_d^{(K-k+1,K)}(u_d) \right)$$

(22)

by letting for all $j \in \{1, \ldots, d\}$:

$$g_j^{(K-k+1,K)} = g_j^{(K-k,K-1)} \circ f_{j}^{(K)}$$

for all $1 \leq k \leq K - 1$ (23)

$$g_j^{(1,K)} = \frac{\text{Id}}{f_{j}^{(K)}}.$$  (24)

As a first result, (22) proves (9) while (24) proves (10). Letting $\ell = K - k + 1$ and in view of (21), equation (23) can be rewritten for all $2 \leq \ell \leq K$ as

$$g_j^{(\ell,K)} = g_j^{(\ell-1,K-1)} \circ f_{j}^{(K)}$$

$$= \prod_{i=K-\ell+2}^{K-1} f_{j_i}^{(i)} \circ f_{j}^{(K)}$$

$$= \prod_{i=K-\ell+2}^{K} f_{j_i}^{(i)} \circ f_{j}^{(K)}$$

25
Using the formula (Nelsen, 2007, Eq. 2.4.1),

\[ f(\partial A) \]

defines the partition. The expression (15) of the copula \( \tilde{C} \).

Conversely, let us prove that any Liebscher copula can be constructed iteratively by (7), (8). Let \( g_j(k), j \in \{1, \ldots, d\}, k \in \{1, \ldots, K\} \) be the set of functions associated with Liebscher copula (1).

Our goal is to find a set of functions \( f_j(k), j \in \{1, \ldots, d\}, k \in \{1, \ldots, K\} \) verifying the set of equations (7), (8). For all \( j \in \{1, \ldots, d\} \), define \( f_j(k) := \text{Id} / g_j(1) \) and, for all \( k \in \{K - 1, \ldots, 1\} \),

\[ f_j(k) := \text{Id} \left/ \left( g_j((K + 1) - k) \circ (F_j((K + 1) - 1)) \right) \right. \text{ where } F_j((K + 1) := \bigcirc_{i=k+1}^K f_j(i). \quad (25) \]

Let \( j \in \{1, \ldots, k\} \). The first part of the proof consists in establishing that \( F_j((k + 1) \) is strictly increasing \([0, 1] \rightarrow [0, 1]\) and thus that its inverse \((F_j((k + 1))^{-1} \) is well-defined. To this end, remark that \( F_j(K) = \text{Id} \) by definition and \( F_j(k) = f_j(k) \circ F_j(k + 1) = F_j((k + 1)) / g_j(k) \), in view of (11). Iterating, it follows that

\[ F_j((k + 1) = \text{Id} \left/ \left( \prod_{i=2}^{K-k} g_j(i) \right) \right. \text{ where } F_j(K) := \left( \prod_{i=K-k+1}^K g_j(i) \right) \]

in view of (2). It is then clear that \( F_j((k + 1) \) is strictly increasing \([0, 1] \rightarrow [0, 1]\). The goal of the second part of the proof is to show that \( f_j(k) \in \mathcal{F} \) for all \( k \in \{1, \ldots, K\} \). It is clear that \( \text{Id} / f_j(k) \) is strictly increasing for all \( k \in \{1, \ldots, K\} \) from (25). Besides, as already noticed, \( f_j(k) \circ F_j((k + 1)) = f_j(k) \), and thus \( f_j(k) \) is strictly increasing as the composition of strictly increasing functions. This concludes the proof that \( f_j(k) \in \mathcal{F} \). The third part of the proof consists in showing that \( f_j(k), k \in \{1, \ldots, K\} \) is solution of the set of equations (10), (11). It is readily seen that (10) holds and

\[ \bigcirc_{i=K-k+2}^K f_j(i) \big/ \bigcirc_{i=K-k+1}^K f_j(i) = F_j((K + 2) / F_j((K + 1)) = g_j(k) \]

which proves (11).

\[ \textbf{Proof of Proposition 6.} \] The expression (15) of the copula \( \tilde{C}_F \) is a simple consequence of the definition of the partition \( \mathcal{A}_0, \ldots, \mathcal{A}_K \). We only derive the singular component expression in the case of a product of two terms, \( K = 2 \); the general case follows similar lines. Denote \( p_1 \) and \( q_1 \) by \( p \) and \( q \), then \( \tilde{C}_F(u, v) \) can be respectively written on \( \mathcal{A}_0, \mathcal{A}_1 \), and \( \mathcal{A}_2 \) by \( u, u^{1-p}v^q \) and \( v \). The cross derivative \( \frac{\partial^2 \tilde{C}_F}{\partial u \partial v}(x, y) \) then vanishes on \( \mathcal{A}_0 \) and \( \mathcal{A}_2 \), and is equal to \( (1-p)q x^{-p} y^{-q-1} \) on \( \mathcal{A}_1 \).

Using the formula (Nelsen, 2007, Eq. 2.4.1),

\[ \tilde{A}_F(u, v) = \int_0^u \int_0^v \frac{\partial^2 \tilde{C}_F}{\partial u \partial v}(x, y) \, dx \, dy, \]

and dividing the double integral above into the three sets of \([0, u] \times [0, v]\) intersected with \( \mathcal{A}_0, \mathcal{A}_1 \), and \( \mathcal{A}_2 \) yields

\[ \tilde{A}_F(u, v) = \int_{[0, u] \times [0, v] \cap \mathcal{A}_1} \frac{\partial^2 \tilde{C}_F}{\partial u \partial v}(x, y) \, dx \, dy, \]

and therefore routine calculations yield the following expressions:

\[ \tilde{A}_F(u, v) = \begin{cases} 
- (1-q)u^{\frac{1}{1-q}} + (1-p)u & \text{ if } (u, v) \in \mathcal{A}_0, \\
- (1-q)u^{\frac{1}{1-q}} + u^{1-p}v^q - pv^q & \text{ if } (u, v) \in \mathcal{A}_1, \\
qv - pv^q & \text{ if } (u, v) \in \mathcal{A}_2.
\]

26
Taking the difference $\tilde{S}_F = \tilde{C}_F - \tilde{A}_F$ yields a simple expression for the singular component

$$\tilde{S}_F(u,v) = p \min(u, v^q) + (1-q) \min(u^{1-p}, v) = p \min(u^p, v^q) + (1-q) \min(u^{1-p}, v^{1-q}) \leq 1.$$

(26)

Given that $r_1 \leq r_2$ yields $p \leq q$ in the case $K = 2$, thus leading to expression (16) when $K = 2$. The general case $K > 2$ is derived similarly.

**Proof of Proposition 7.** (i) Taking account of the identity $\min(x, y) + \max(x, y) = x + y$ yields

$$\tilde{C}_F \left( \frac{1}{2}, \frac{1}{2} \right) = \prod_{k=1}^K \min(2^{-p_k}, 2^{-q_k}) = 2^{-\sum_{k=1}^K \max(p_k, q_k)} = 2^{\sum_{k=1}^K \min(p_k, q_k) - 2}$$

and consequently

$$\beta(\tilde{C}_F) = 2^{\sum_{k=1}^K \min(p_k, q_k) - 1}.$$

(ii) We use the following expression of Kendall’s $\tau$, which is convenient since the copula $\tilde{C}_F$ may have non null singular component (Nelsen, 2007, Eq. 5.1.12):

$$\tau(\tilde{C}_F) = 1 - 4 \int_{[0,1]^2} \frac{\partial}{\partial u} \tilde{C}_F(u,v) \frac{\partial}{\partial v} \tilde{C}_F(u,v) du dv$$

$$= 1 - 4 \sum_{k=0}^K \int_{A_k} \frac{\partial}{\partial u} \tilde{C}_F(u,v) \frac{\partial}{\partial v} \tilde{C}_F(u,v) du dv.$$

Let $k \in \{0, \ldots, K\}$. Then, for all $(u,v) \in A_k$, one has

$$\frac{\partial \tilde{C}_F}{\partial u}(u,v) = (1 - \bar{p}_k)u^{-\bar{p}_k}v^{\bar{q}_k},$$

$$\frac{\partial \tilde{C}_F}{\partial v}(u,v) = \bar{q}_ku^{1-\bar{p}_k}v^{-1}. $$

Besides, remarking that $q_0 = 0$ and $\bar{p}_K = 1$ shows that both terms $k = 0$ and $k = K$ do not contribute to the sum in $\tau(\tilde{C}_F)$. The result

$$\tau(\tilde{C}_F) = 1 - \sum_{k=1}^{K-1} \frac{(1 - \bar{p}_k)\bar{q}_k(r_{k+1} - r_k)}{(\bar{q}_kr_k + (1 - \bar{p}_k))(\bar{q}_kr_{k+1} + (1 - \bar{p}_k))}$$

then follows.

(iii) Recall that

$$\rho(\tilde{C}_F) = 12 \int_{[0,1]^2} \tilde{C}_F(u,v) du dv - 3$$

$$= 12 \sum_{k=0}^K \int_{A_k} \tilde{C}_F(u,v) du dv - 3$$

$$= 12 \sum_{k=0}^K \int_{A_k} u^{1-\bar{p}_k}v^{\bar{q}_k} du dv - 3$$

$$= 12(1 + r_1 + r_1 r_K) \frac{r_{k+1} - r_k}{(2 + r_1)(1 + 2r_K)} - 3 + \sum_{k=1}^{K-1} \frac{r_{k+1} - r_k}{(1 + \bar{q}_k)r_k + (2 - \bar{p}_k))(1 + \bar{q}_kr_{k+1} + (2 - \bar{p}_k))}.$$
A.2 Auxiliary results

**Lemma 1.** Let \( \varphi : \mathbb{R}^d_+ \to \mathbb{R} \) be a continuous function such that
\[
\varphi(x) = \varphi(ax) + \varphi((1-a)x)
\] (27)
for all \( a \in (0,1) \) and \( x \in \mathbb{R}^d_+ \). Then, necessarily, \( \varphi \) is homogeneous of degree 1.

**Proof.** — First, let us prove by induction the property \((P_n)\): \( \varphi(x/n) = \varphi(x)/n \) for all \( n \in \mathbb{N} \setminus \{0\} \) and \( x \in \mathbb{R}^d_+ \). \((P_1)\) is straightforwardly true. Assume \((P_n)\) holds. Then,
\[
\varphi\left(\frac{x}{n+1}\right) = \varphi\left(\frac{x}{n+1} + \frac{nx}{n+1}\right) = \frac{1}{n}\varphi\left(\frac{nx}{n+1}\right)
\]
and \((27)\) entails
\[
\varphi(x) = \varphi\left(\frac{x}{n+1}\right) + \varphi\left(\frac{nx}{n+1}\right) = \varphi\left(\frac{x}{n+1}\right) + n\varphi\left(\frac{x}{n+1}\right) = (n+1)\varphi\left(\frac{x}{n+1}\right)
\]
which proves \((P_{n+1})\).

— Second, for all \( m \in \mathbb{N} \setminus \{0\} \), \((P_n)\) shows that \( \varphi(x) = m\varphi(x/m) \) and thus, letting \( y = x/m \), \( \varphi(my) = m\varphi(y) \) for all \( y \in \mathbb{R}^d_+ \). This property can be extended to \( m = 0 \) since letting \( a \to 0 \) in \((27)\) yields \( \varphi(0) = 0 \).

— Third, let \( q \in \mathbb{Q}_+ \). There exists \((m,n) \in \mathbb{N} \times \mathbb{N} \setminus \{0\}\) such that \( q = m/n \). From the first two points, \( \varphi(qx) = \varphi(mx/n) = m\varphi(x/n) = m\varphi(x)/n = q\varphi(x) \).

— Finally, the continuity of \( \varphi \) and the density of \( \mathcal{Q}_+ \) in \( \mathbb{R}^d_+ \) imply that \( \varphi(tx) = t\varphi(x) \) for all \( t \in \mathbb{R}_+ \) and \( x \in \mathbb{R}^d_+ \). The result is thus proved.

**Lemma 2.** For all \( k \geq 1 \) let \( C_k \) be a \( d \)-variate copula and \( f_j^{(k)}(t) \in \mathcal{F} \) for all \( j \in \{1,\ldots,d\} \), with the assumption \( f_j^{(1)}(t) = 1 \) for all \( t \in [0,1] \). The sequence \( \hat{C}^{(k)} \) defined iteratively by \((7)\) and \((8)\) is a sequence of \( d \)-variate copulas.

**Proof.** The proof is done by induction on \( k \). Let \( \mathcal{C} \) be the set of all \( d \)-variate copulas. First, it is clear that \( \hat{C}^{(1)} \in \mathcal{C} \) from \((7)\). Second, let us assume that \( \hat{C}^{(k-1)} \in \mathcal{C} \) and prove that \( \hat{C}^{(k)} \in \mathcal{C} \) for all \( k \geq 2 \). Let \( (Y_1,\ldots,Y_d) \) and \( (Z_1,\ldots,Z_d) \) be two independent random vectors in \([0,1]^d\) drawn respectively from the cdf \( \hat{C}^{(k-1)}(f_1^{(k)}(u_1),\ldots,f_d^{(k)}(u_d)) \) and \( C_K(Id/f_1^{(k)}(u_1),\ldots,Id/f_d^{(k)}(u_d)) \). For all \( j \in \{1,\ldots,d\} \) define the random variable \( X_j = \max(Y_j,Z_j) \). For all \( u \in [0,1]^d \), the cdf of \((X_1,\ldots,X_d)\) is given by
\[
P(X_1 \leq u_1,\ldots,X_d \leq u_d) = P(Y_1 \leq u_1,\ldots,Y_d \leq u_d)P(Z_1 \leq u_1,\ldots,Z_d \leq u_d)
= \hat{C}^{(k-1)}(f_1^{(k)}(u_1),\ldots,f_d^{(k)}(u_d))C_K(u_1/f_1^{(k)}(u_1),\ldots,u_d/f_d^{(k)}(u_d))
= \hat{C}^{(k)}(u),
\]
from \((8)\). This proves that \( \hat{C}^{(k)} \) is a cdf. The margins are uniform by construction.
