Abstract

We study the superhedging prices and the associated superhedging strategies for American options in a non-linear incomplete market model with default. The points of view of the seller and of the buyer are presented. The underlying market model consists of a risk-free asset and a risky asset driven by a Brownian motion and a compensated default martingale. The portfolio processes follow non-linear dynamics with a non-linear driver $f$. We give a dual representation of the seller’s (superhedging) price for the American option associated with a completely irregular payoff ($\xi_t$) (not necessarily càdlàg) in terms of the value of a non-linear mixed control/stopping problem. The dual representation involves a suitable set of equivalent probability measures, which we call $f$-martingale probability measures. We also provide two infinitesimal characterizations of the seller’s price process: in terms of the minimal supersolution of a constrained reflected BSDE and in terms of the minimal supersolution of an optional reflected BSDE. Under some regularity assumptions on $\xi$, we also show a duality result for the buyer’s price in terms of the value of a non-linear control/stopping game problem.

Key-words: American options, incomplete markets, non-linear pricing, constrained reflected BSDE, $f$-expectation, control problems with non-linear expectation, optimal stopping with non-linear expectation, non-linear optional decomposition, pricing-hedging duality

1 Introduction

We consider a financial market with a default time $\vartheta$. The market contains one risky asset whose price dynamics are driven by a one-dimensional Brownian motion and a compensated

default martingale. We study the case of a market with imperfections which are encoded in the non-linearity of the portfolio dynamics. Imperfections entering into this framework include different borrowing and lending interest rates (cf. [28], [7]), different repo rates (cf. [4]), the presence of a large investor (cf. [8], [2], [11]), among others. We note that our market is *incomplete* in the sense that not every European contingent claim can be replicated by a portfolio. In this framework, our paper [23] studies the problem of pricing and hedging of European options (from the point of view of the seller and of the buyer). In the present paper, we focus on the problem of pricing and hedging of American options from the point of view of the seller and of the buyer.

We recall that in the case of a *non-linear complete* market, the seller’s (superhedging) price of the American option with a càdlàg payoff \( (\xi_t) \) is equal to the value of the optimal stopping problem with non-linear \( f \)-evaluation/expectation, associated with the given payoff \( (\xi_t) \) (cf. [14]). Moreover, the price process admits an infinitesimal characterization as the solution of the reflected BSDE associated with driver \( f \) and obstacle \( (\xi_t) \): cf. [19] in the Brownian case and for a continuous payoff \( (\xi_t) \), and [36] (resp. [14]) in the case of Poisson jumps (resp. a default jump) and a càdlàg process \( (\xi_t) \). More recently, these results have been generalized to the case of an irregular payoff \( (\xi_t) \) (not necessarily càdlàg) in [20] and [21].

In the *non-linear incomplete* market of the present paper, we provide a dual formulation of the seller’s (superhedging) price \( u_0 \) of the American option associated with an irregular payoff \( (\xi_t) \) (not necessarily càdlàg) in terms of the value of a non-linear mixed control/stopping problem. The dual representation involves a suitable set \( Q \) of equivalent probability measures, which we call \( f \)-martingale probability measures. More precisely, we show that \( u_0 \) is equal to the supremum, over all \( f \)-martingale measures \( Q \in Q \) and over all stopping times \( \tau \), of the \( (f,Q) \)-evaluation of \( \xi_\tau \) at time 0, that is,

\[
\begin{equation}
    u_0 = \sup_{(Q,\tau) \in Q \times \tau} E^{f_Q,0,\tau}_{\xi_\tau}.
\end{equation}
\]

In the case when \( f \) is linear and \( (\xi_t) \) is càdlàg, our result reduces to the well-known dual representation from the literature on linear incomplete markets (cf. [29]). We also provide two types of infinitesimal characterizations of the (superhedging) price \( u_0 \) for the seller: in terms of the minimal supersolution of a *constrained reflected BSDE* with default (associated with the driver \( f \) and the obstacle \( (\xi_t) \)), and in terms of the minimal supersolution of an *optional reflected BSDE* with default. We note that, even in the linear case \( (f \text{ linear}) \), these results are new, since in the literature, only the càdlàg case has been studied. The treatment of the non càdlàg case requires the introduction of an additional non decreasing process corresponding to the right-hand jumps of the price process. Using some specific techniques of the control theory and the general theory of processes, we show that this process increases only when the price is equal to the payoff. The proofs of the dual representation and of the infinitesimal characterizations rely also on the non-linear optional decomposition of optional (not necessarily càdlàg) processes which are \( (f,Q) \)-strong supermartingales for all \( Q \in Q \) (cf. our result established in [23]).

Under some regularity assumptions on the payoff \( \xi \), we also show a dual representation for
the buyer’s superhedging price at time 0, denoted by $\tilde{u}_0$, in terms of the value of a non-linear control/stopping game problem, which can be written as

$$
\tilde{u}_0 = \sup_{\tau \in T} \inf_{Q \in \mathcal{Q}} \{ -\xi_{Q,0,\tau}(\xi_{\tau}) \} = \inf_{Q \in \mathcal{Q}} \sup_{\tau \in T} \{ -\xi_{Q,0,\tau}(\xi_{\tau}) \}.
$$

(1.2)

We note that, contrary to the case of a European option (studied in [23]), the buyer’s price is not equal to the opposite of the seller’s price of the American option associated with the payoff $-\xi$.

The rest of the paper is organized as follows: In Section 2, we introduce some notation and definitions. In Section 3, we first present our market model (Subsection 3.1), we then introduce the set $\mathcal{Q}$ of $f$-martingale probability measures (Subsection 3.2), we define the buyer’s and seller’s superhedging prices of the American option and we discuss no-arbitrage issues (Subsection 3.3). In Section 4, we establish the duality result for the seller’s superhedging price. For this, we first study the value $Y$ of the associated non-linear mixed control/stopping problem, which we write as the (essential) supremum of a family of reflected BSDEs. We show in particular that $Y$ is the smallest optional process which is an $(f,Q)$-strong supermartingale for all $Q \in \mathcal{Q}$, and which dominates the payoff process. We also study the strict value $Y^+$ of our non-linear mixed control/stopping problem. We show, in particular, that $Y^+$ can be aggregated by a càdlàg adapted process. We then give the proof of the dual representation of the seller’s superhedging price (1.1). In Section 5, we provide the two infinitesimal characterizations of the seller’s superhedging price process. Section 6 is devoted to the point of view of the buyer. We first study the value $\tilde{Y}$ of the associated dual problem, which we write as the (essential) infimum of a family of reflected BSDEs. Then, under some regularity assumptions on the payoff, we prove the dual representation of the buyer’s superhedging price (1.2). We also introduce and discuss the notion of buyer’s nearly superhedging price. The Appendix contains some useful technical results and a discussion on reflected BSDEs with a non positive jump at the default time.

## 2 Notation and definitions

Let $(\Omega, \mathcal{G}, P)$ be a complete probability space equipped with two stochastic processes: a unidimensional standard Brownian motion $W$ and a jump process $N$ defined by $N_t = 1_{\vartheta \leq t}$ for all $t \in [0,T]$, where $\vartheta$ is a random variable which models a default time. We assume that this default can appear after any fixed time, that is $P(\vartheta \geq t) > 0$ for all $t \geq 0$. We denote by $\mathcal{G} = \{ \mathcal{G}_t, t \geq 0 \}$ the augmented filtration generated by $W$ and $N$. We denote by $\mathcal{P}$ the predictable $\sigma$-algebra. We suppose that $W$ is a $\mathcal{G}$-Brownian motion. Let $(\Lambda_t)$ be the predictable compensator of the nondecreasing process $(N_t)$. Note that $(\Lambda_{t \wedge \vartheta})$ is then the predictable compensator of $(N_{t \wedge \vartheta}) = (N_t)$. By uniqueness of the predictable compensator, $\Lambda_{t \wedge \vartheta} = \Lambda_t$, $t \geq 0$ a.s. We assume that $\Lambda$ is absolutely continuous w.r.t. Lebesgue’s measure, so that there exists a nonnegative process $\lambda$, called the intensity process, such that $\Lambda_t = \int_0^t \lambda_s ds$, $t \geq 0$. To simplify the presentation, we suppose that $\lambda$ is bounded. Since $\Lambda_{t \wedge \vartheta} = \Lambda_t$,
λ vanishes after \( \vartheta \). Let \( M \) be the compensated martingale given by

\[
M_t := N_t - \int_0^t \lambda_\omega ds.
\]

Let \( T > 0 \) be the terminal time. We define the following sets:

- \( S^2 \) is the set of \( \mathcal{G} \)-adapted RCLL processes \( \varphi \) such that \( \mathbb{E}[\sup_{0 \leq t \leq T} |\varphi_t|^2] < +\infty \).
- \( A^2 \) is the set of real-valued non decreasing RCLL \( \mathcal{G} \)-predictable processes \( A \) with \( A_0 = 0 \) and \( \mathbb{E}(A_T^2) < \infty \).
- \( \mathbb{H}^2 \) is the set of \( \mathcal{G} \)-predictable processes \( Z \) such that \( |||Z|||^2 := \mathbb{E}\left[\int_0^T |Z_t|^2 dt\right] < \infty \).
- \( \mathbb{H}^2_\lambda := L^2(\Omega \times [0, T], \mathcal{P}, \lambda_t dP \otimes dt) \), equipped with the norm \( ||U||^2_\lambda := \mathbb{E}\left[\int_0^T |U_t|^2 \lambda_t dt\right] < \infty \).

Note that, without loss of generality, we may assume that if \( U \in \mathbb{H}^2_\lambda \), it vanishes after \( \vartheta \).

- We denote by \( T \) the set of stopping times \( \tau \) such that \( \tau \in [0, T] \) a.s.
- For \( S \) in \( T \), we denote by \( T_S \) the set of stopping times \( \tau \) such that \( S \leq \tau \leq T \) a.s.

As in [21], the notation \( S^2 \) stands for the vector space of \( \mathbb{R} \)-valued optional (not necessarily cadlag) processes \( \phi \) such that \( |||\phi|||^2_{S^2} := E[\text{ess sup}_{\tau \in T_\omega} |\phi_\tau|^2] < \infty \). By Proposition 2.1 in [21], the space \( S^2 \) endowed with the norm \( |||\cdot|||^2_{S^2} \) is a Banach space. We note that the space \( S^2 \) is the sub-space of RCLL processes of \( S^2 \).

Recall that in this setup, we have a martingale representation theorem with respect to \( W \) and \( M \) (see [24], [30]).

We give the definition of a \( \lambda \)-admissible driver:

**Definition 2.1 (Driver, \( \lambda \)-admissible driver).** A function \( g \) is said to be a driver if \( g : \Omega \times [0, T] \times \mathbb{R}^3 \rightarrow \mathbb{R} \) is \( \mathcal{P} \otimes \mathcal{B}(\mathbb{R}^3) \)- measurable, and such that \( g(\omega, 0, 0, 0) \in \mathbb{H}^2 \). A driver \( g \) is called a \( \lambda \)-admissible driver if moreover there exists a constant \( C \geq 0 \) such that \( dP \otimes dt \)-a.s., for each \( (y_1, z_1, k_1), (y_2, z_2, k_2) \),

\[
|g(t, y_1, z_1, k_1) - g(t, y_2, z_2, k_2)| \leq C(|y_1 - y_2| + |z_1 - z_2| + \sqrt{\lambda_t}|k_1 - k_2|). \tag{2.1}
\]

A nonnegative constant \( C \) which satisfies this inequality is called a \( \lambda \)-constant associated with driver \( g \).

By condition (2.1) and since \( \lambda_t = 0 \) on \( ]\vartheta, T] \), \( g \) does not depend on \( k \) on \( ]\vartheta, T] \).

Let \( g \) be a \( \lambda \)-admissible driver. For all \( \eta \in L^2(\mathcal{G}_T) \), there exists a unique solution \((X(T, \eta), Z(T, \eta), K(T, \eta))\) (denoted simply by \((X, Z, K)\)) in \( S^2 \times \mathbb{H}^2 \times \mathbb{H}^2_\lambda \) of the following BSDE (see [11]):

\[
-dX_t = g(t, X_t, Z_t, K_t)dt - Z_t dW_t - K_t dM_t; \quad X_T = \eta. \tag{2.2}
\]
We call $g$-conditional expectation, denoted by $\mathcal{E}^g$, the operator defined for each $T' \in [0, T]$ and for each $\eta \in L^2(\mathcal{G}_{T'})$ by $\mathcal{E}^g_{t,T'}(\eta) := X_t(T', \eta)$ a.s. for all $t \in [0, T']$.

We introduce the following assumption:

**Assumption 2.2.** Assume that there exists a bounded map

$$
\gamma : \Omega \times [0, T] \times \mathbb{R}^4 \to \mathbb{R} ; (\omega, t, y, z, k_1, k_2) \mapsto \gamma^{y,z,k_1,k_2}_t(\omega)
$$

$\mathcal{P} \otimes \mathcal{B}(\mathbb{R}^4)$-measurable and satisfying $d\mathbb{P} \otimes dt$-a.s., for all $(y, z, k_1, k_2) \in \mathbb{R}^4$,

$$
\begin{align*}
g(t, y, z, k_1) - g(t, y, z, k_2) & \geq \gamma^{y,z,k_1,k_2}_t(k_1 - k_2)\lambda_t, \\
\gamma^{y,z,k_1,k_2}_t & > -1.
\end{align*}
$$

Assumption 2.2 ensures the strict monotonicity of the operator $\mathcal{E}^g$ with respect to terminal condition (see [11, Section 3.3]).

**Definition 2.3.** Let $Y \in \mathbb{S}^2$. The process $(Y_t)$ is said to be a strong $\mathcal{E}^g$-supermartingale $^1$ (resp. martingale) if $\mathcal{E}^g_{\sigma,\tau}(Y_\tau) \leq Y_\sigma$ (resp. $= Y_\sigma$) a.s. on $\sigma \leq \tau$, for all $\sigma, \tau \in T_0$.

Note that, by the flow property of BSDEs, for each $\tau \in T_0$ and for each $\eta \in L^2(\mathcal{G}_{\tau})$, the process $\mathcal{E}^g_{\tau}(\eta)$ is an $\mathcal{E}^g$-martingale.

## 3 Market model, $f$-martingale measures and superhedging prices

### 3.1 Market model $\mathcal{M}^f$

We now consider a financial market which consists of one risk-free asset, whose price process $S^0 = (S^0_t)_{0 \leq t \leq T}$ satisfies $dS^0_t = S^0_t r_t dt$, and one risky asset with price process $S$ which admits a discontinuity at time $\vartheta$. Throughout the sequel, we consider that the price process $S = (S_t)_{0 \leq t \leq T}$ evolves according to the equation

$$
dS_t = S_t^{-1}(\mu_t dt + \sigma_t dW_t + \beta_t dM_t).
$$

All the processes $r, \mu, \beta$ are supposed to be predictable (that is $\mathcal{P}$-measurable), satisfying $\sigma_t > 0$ $d\mathbb{P} \otimes dt$ a.s. and $\beta_0 > -1$ a.s., and such that $\sigma, \lambda, \sigma^{-1}, \beta$ are bounded.

We consider an investor with an initial wealth equal to $x$, who can invest his/her wealth in the two assets of the market. At each time $t$, the investor chooses the amount $\varphi_t$ of wealth invested in the risky asset. A process $\varphi = (\varphi_t)_{0 \leq t \leq T}$ is called a *portfolio strategy* if it belongs to $\mathbb{H}^2$. The value of the associated portfolio (also called *wealth*) at time $t$ is denoted by $V_t^{x,\varphi}$ (or simply $V_t$).

$^1$In the case where $Y$ is moreover RCLL (that is, $Y \in S^2$), we often omit the term ”strong”. 
We assume now that the dynamics of the wealth is non-linear. More precisely, let $x \in \mathbb{R}$ be an initial wealth and let $\varphi$ in $\mathbb{H}^2$ be a portfolio strategy. We suppose that the associated wealth process $V_t^{x,\varphi}$ (or simply $V_t$) satisfies the following (forward) dynamics:

$$-dV_t = f(t, V_t, \varphi_t \sigma_t) dt - \varphi_t \sigma_t dW_t - \varphi_t \beta_t dM_t,$$

(3.2)

with $V_0 = x$, where $f$ is a non-linear $\lambda$-admissible driver which does not depend on $k$, such that $f(t, 0, 0) = 0$.  

We recall the following lemma (cf. Lemma 3.1 in [23]).

**Lemma 3.1.** For each $x \in \mathbb{R}$ and each $\varphi$ in $\mathbb{H}^2$, the associated wealth process $(V_t^{x,\varphi})$ is an $\mathcal{E}^f$-martingale.

We emphasize that for an arbitrary random variable $\eta \in L^2$, there does not necessarily exist a pair of processes $(X, \varphi)$ such that $(X_t, \varphi_t \sigma_t, \varphi_t \beta_t)$ is solution of the BSDE with default jump associated with driver $f$ and terminal condition $\eta$, that is, such that $(X, \varphi)$ satisfies the dynamics (3.2) with $X_T = \eta$. In other terms, the market is incomplete.

In the sequel, we will often use the following change of variables which maps a process $\varphi \in \mathbb{H}^2$ to $Z \in \mathbb{H}^2$ defined by $Z_t = \varphi_t \sigma_t$. With this change of variables, the wealth process $V = V_t^{x,\varphi}$ (for a given $x \in \mathbb{R}$) is the unique process satisfying

$$-dV_t = f(t, V_t, Z_t) dt - Z_t dW_t - Z_t \sigma_t^{-1} \beta_t dM_t, \quad V_0 = x.$$  

(3.3)

We recall that in the classical linear case, we have $f(t, y, z) = -r_t y - z \theta_t$, where $\theta_t := \frac{\mu_t - r_t}{\sigma_t}$.

### 3.2 $f$-martingale measures

We recall the notion of $f$-evaluation under $Q$ (denoted by $\mathcal{E}^f_Q$), the notion of $\mathcal{E}^f_Q$-martingale, and the notion of $f$-martingale measure (cf. [23]).

Let $Q$ be a probability measure, equivalent to $P$. From the $\mathcal{G}$-martingale representation theorem (cf. [30], [25]), its density process $(\zeta_t)$ satisfies

$$d\zeta_t = \zeta_t (\alpha_t dW_t + \nu_t dM_t); \quad \zeta_0 = 1,$$

(3.4)

where $(\alpha_t)$ and $(\nu_t)$ are predictable processes with $\nu_{\theta \wedge T} > -1$ a.s. By Girsanov’s theorem, the process $W_t^Q := W_t - \int_0^t \alpha_s ds$ is a Brownian motion under $Q$, and the process $M_t^Q := M_t - \int_0^t \nu_s \lambda_s ds$ is a martingale under $Q$.

As in [23], we define the spaces $S^2_Q$, $\mathbb{H}^2_Q$ and $\mathbb{H}^2_{Q, \lambda}$ similarly to $S^2$, $\mathbb{H}^2$ and $\mathbb{H}^2_{\lambda}$, but under probability $Q$ instead of $P$.

---

2 so that $\mathcal{E}^f_{T'}(0) = 0$ for all $T' \in [0, T]$. 

6
Definition 3.2. We call $f$-evaluation under $Q$, or $(f,Q)$-evaluation in short, denoted by $\mathcal{E}_Q^f$, the operator defined for each $T' \in [0,T]$ and for each $\eta \in L_2^2(\mathcal{G}_T)$ by $\mathcal{E}_Q^f(\eta) := X_t$ for all $t \in [0,T']$, where $(X,Z,K)$ is the solution in $S_Q^2 \times H_Q^2 \times H_Q^2$ of the BSDE under $Q$ associated with driver $f$, terminal time $T'$ and terminal condition $\eta$, and driven by $W^Q$ and $M^Q$, that is \(^3\)

$$-dX_t = f(t,X_t,Z_t)dt - Z_t dW_t^Q - K_t dM_t^Q; \quad X_{T'} = \eta.$$  

We note that $\mathcal{E}_P^f = \mathcal{E}_Q^f$.

Definition 3.3. Let $Y \in S_Q^2$. The process $(Y_t)$ is said to be a (strong) $\mathcal{E}_Q^f$-martingale, or an $(f,Q)$-martingale, if $\mathcal{E}_{Q,\sigma,\tau}^f(Y_\cdot) = Y_\sigma$ a.s. on $\sigma \leq \tau$, for all $\sigma,\tau \in T_0$.

We now introduce the concept of $f$-martingale probability measure.

Definition 3.4. A probability measure $Q$ equivalent to $P$ is called an $f$-martingale probability measure if for all $x \in \mathbb{R}$ and for all $\varphi \in H^2 \cap H_Q^2$, the wealth process $V^{x,\varphi}$ is a strong $\mathcal{E}_Q^f$-martingale, or in other terms an $(f,Q)$-martingale.

We note that $P$ is an $f$-martingale probability measure (cf. Lemma 3.1).

As in [23], we denote by $Q$ the set of $f$-martingale probability measures $Q$ such that the coefficients $(\alpha_t)$ and $(\nu_t)$ associated with its density with respect to $P$ (see equation (3.4)) are bounded. We note that $P \in Q$.

We denote by $V$ be the set of bounded predictable processes $\nu$ such that $\nu_{\theta \wedge T} > -1$ a.s., which is equivalent to $\nu_t > -1$ for all $t \in [0,T] \lambda dt \otimes dt$-a.s. (cf. Remark 9 in [11]).

Proposition 3.5. (Characterization of $Q$) Let $Q$ be a probability measure equivalent to $P$, such that the coefficients $\alpha$ and $\nu$ of its density (3.4) with respect to $P$ are bounded. The two following assertions are equivalent:

(i) $Q \in Q$, that is, $Q$ is an $f$-martingale probability measure.

(ii) there exists $\nu \in V$ such that $Q = Q^\nu$, where $Q^\nu$ is the probability measure which admits $\zeta_T^\nu$ as density with respect to $P$ on $\mathcal{G}_T$, where $\zeta_T^\nu$ satisfies

$$d\zeta_t^\nu = \zeta_t^\nu (-\nu_t \lambda_t \beta_t \sigma_t^{-1} dW_t + \nu_t dM_t); \quad \zeta_0^\nu = 1. \quad (3.5)$$

3.3 Superhedging prices and no-arbitrage

Let us consider an American option associated with maturity $T$ and a payoff given by a process $(\xi_t) \in S^2$.

The superhedging price for the seller of the American option at time 0, denoted by $u_0$, is classically defined as the minimal initial capital which enables the seller to be superhedged no matter what the exercise time chosen by the buyer is. More precisely, we have the following definition.

---

3We note that since we have a representation theorem for $(Q,\mathcal{G})$-martingales with respect to $W^Q$ and $M^Q$ (see e.g. Proposition 6 in the appendix of [11]), this BSDE admits a unique solution $(X,Z,K)$ in $S_Q^2 \times H_Q^2 \times H_Q^2$. 

7
Definition 3.6. A superhedge for the seller against the American option with initial price \( x \in \mathbb{R} \) is a portfolio strategy \( \varphi \in \mathcal{H}^2 \) such that \( V^{x,\varphi}_t \geq \xi_t \), \( 0 \leq t \leq T \) a.s.

For each \( x \in \mathbb{R} \), we denote by \( \mathcal{A}(x) \) the set of all superhedges for the seller associated with initial price \( x \).

The superhedging price for the seller of the American option at time 0 is thus defined by

\[
u_0 := \inf \{ x \in \mathbb{R}, \exists \varphi \in \mathcal{A}(x) \}.
\]

We now consider the American option from the point of view of the buyer.

Definition 3.7. A superhedge for the buyer against the American option with initial price \( z \in \mathbb{R} \) is a pair \((\tau, \varphi)\) of a stopping time \( \tau \in \mathcal{T} \) and a portfolio strategy \( \varphi \in \mathcal{H}^2 \) such that \( V^{-z,\varphi}_\tau + \xi_\tau \geq 0 \) a.s.

For each \( z \in \mathbb{R} \), we denote by \( \mathcal{B}(z) \) the set of all superhedges for the buyer associated with initial price \( z \).

We now define the buyer’s price \( \tilde{u}_0 \) of the American option as the supremum of the initial prices which allow the buyer to be superhedged, that is

\[
\tilde{u}_0 = \sup \{ z \in \mathbb{R}, \exists (\tau, \varphi) \in \mathcal{B}(z) \}.
\]

We now introduce the definitions of an arbitrage opportunity for the seller and for the buyer of the American option.

Definition 3.8. Let \( x \in \mathbb{R} \). Let \( y \in \mathbb{R} \), and let \( \varphi \in \mathcal{H}^2 \). We say that \((y, \varphi)\) is an arbitrage opportunity for the seller of the American option with initial price \( x \) if

\[
y < x \quad \text{and} \quad V^{y,\varphi}_\tau - \xi_\tau \geq 0 \quad \text{a.s.} \quad \text{for all} \quad \tau \in \mathcal{T}.
\]

Definition 3.9. Let \( x \in \mathbb{R} \). Let \( y \in \mathbb{R} \), let \( \tau \in \mathcal{T} \) and let \( \varphi \in \mathcal{H}^2 \). We say that \((y, \tau, \varphi)\) is an arbitrage opportunity for the buyer of the American option with initial price \( x \), if

\[
y > x \quad \text{and} \quad V^{-y,\varphi}_\tau + \xi_\tau \geq 0 \quad \text{a.s.}
\]

Proposition 3.10. Let \( x \in \mathbb{R} \). There exists an arbitrage opportunity for the seller (resp. for the buyer) of the American option with price \( x \) if and only if \( x > u_0 \) (resp. \( x < \tilde{u}_0 \)).

The proof, which relies on the same arguments as those of the proof of Proposition 5.11 in [14] (see also [26]) is omitted.

Definition 3.11. A real number \( x \) is called an arbitrage-free price for the American option if there exists no arbitrage opportunity, neither for the seller nor for the buyer.

By Propositions 3.10, we get

Proposition 3.12. If \( u_0 < \tilde{u}_0 \), there does not exist any arbitrage-free price for the American option. If \( u_0 \geq \tilde{u}_0 \), the interval \([\tilde{u}_0, u_0] \) is the set of all arbitrage-free prices. We call it the arbitrage-free interval for the American option.

\(^4\)Note that \( u_0 \), \( \tilde{u}_0 \in \mathbb{R} \). We shall see below that, under the assumption that \(|\xi_t|\) is smaller than or equal to the value of a portfolio sufficiently integrable (cf. (4.1)), \( u_0 \) is finite (cf. Theorem 4.1), and that, under this assumption and some regularity conditions on \( \xi \), \( \tilde{u}_0 \) is also finite (cf. Theorem 6.1).
4 Duality for the seller’s superhedging price

From now on, we assume that the payoff \((\xi_t)\) is such that there exist \(x \in \mathbb{R}\) and \(\psi \in H^2\) satisfying

\[
|\xi_t| \leq V^{x,\psi}_t = x - \int_0^t f(s, V^{x,\psi}_s, \sigma_s \psi_s) ds + \int_0^t \psi_s \sigma_s dW_s + \int_0^t \beta_s \psi_s dM_s, \quad 0 \leq t \leq T, \quad \text{a.s.}
\]

(4.1)

We will establish the following dual characterization of the seller’s superhedging price (in terms of the \(f\)-martingale measures from Definition 3.4).

**Theorem 4.1 (Duality for the seller’s superhedging price).** Let \((\xi_t)\) satisfy Assumption (4.1) with \(\psi \in \cap_{\nu \in \mathbb{V}} H^2_{Q^\nu}\). The superhedging price for the seller \(u_0\) of the American option with payoff \((\xi_t)\) satisfies the equality

\[
u_0 = \sup_{(\tau, \nu) \in \mathcal{T} \times \mathbb{V}} \mathcal{E}_{Q^\nu}^{f, \tau, \nu}(\xi_{\tau}).
\]

**Remark 4.2.** In the linear case, this result reduces to the well-known dual representation of the superhedging price for the seller of the American option in an incomplete (linear) market (cf. [29]).

In order to prove Theorem 4.1, we will work under the primitive probability \(P\), which will allow us to solve the problem under weaker integrability conditions.

To this aim, we introduce a family of drivers \((f^\nu, \nu \in \mathbb{V})\), which will be used in the sequel.

**Definition 4.3 (Driver \(f^\nu\) and \(\mathcal{E}^\nu\)-expectation).** For \(\nu \in \mathbb{V}\), we define

\[
f^\nu(\omega, t, y, z, k) := f(\omega, t, y, z) + \nu_t(\omega) \lambda_t(\omega) (k - \beta_t(\omega) \sigma_t^{-1}(\omega) z).
\]

The mapping \(f^\nu\) is a \(\lambda\)-admissible driver.\(^5\)

The associated non-linear family of operators, denoted by \(\mathcal{E}^{f^\nu}\) or, simply, \(\mathcal{E}^\nu\), is defined as follows: for each \(T' \leq T\) and each \(\eta \in L^2(\mathcal{G}_{T'})\), we have \(\mathcal{E}^\nu_{\cdot, T'}(\eta) := X^\nu\), where \((X^\nu, Z^\nu, K^\nu)\) is the unique solution in \(S^2 \times H^2 \times H^2_{\lambda}\) of the BSDE

\[
-dX^\nu_t = (f(t, X^\nu_t, Z^\nu_t) + \nu_t \lambda_t (K^\nu_t - \beta_t \sigma_t^{-1} Z^\nu_t)) dt - Z^\nu_t dW_t - K^\nu_t dM_t; \quad X^\nu_{T'} = \eta. \quad (4.2)
\]

**Remark 4.4.** By Proposition 3.5, for each \(\nu \in \mathbb{V}\), for all \(T' \leq T\) and \(\eta \in L^2(\mathcal{G}_{T'}) \cap L^2_{Q^\nu}(\mathcal{G}_{T'})\), we derive that the \((f^\nu, P)\)-evaluation of \(\eta\) is equal to its \((f, Q^\nu)\)-evaluation, that is,

\[
\mathcal{E}^\nu_{\cdot, T'}(\eta) = \mathcal{E}^{f, \nu}_{Q^\nu, \cdot, T'}(\eta).
\]

\(^5\)Since \(\nu\) is a predictable process, \(f^\nu\) is \(\mathcal{P} \otimes \mathcal{B}(\mathbb{R}^3)\)-measurable. As, moreover, \(\nu\) is bounded, \(f^\nu\) is a \(\lambda\)-admissible driver.
4.1 Non-linear problem of control and stopping. The value family \((Y(S))\).

Establishing the dual representation for the seller’s superhedging price is based on the study of the following non-linear problem of control and stopping.

For each \(S \in \mathcal{T}\), let \(Y(S)\) be the \(\mathcal{G}_S\)-measurable random variable defined by

\[
Y(S) := \text{ess sup}_{(\tau,\nu) \in \mathcal{T}_S \times \mathcal{V}} \mathcal{E}^{\nu}_{S,\tau}(\xi_{\tau}). \tag{4.3}
\]

**Remark 4.5.** We note that for each \(S \in \mathcal{T}\), \(\tau \in \mathcal{T}_S\) and each \(\nu \in \mathcal{V}\), the random variable \(\mathcal{E}^{\nu}_{S,\tau}(\xi_{\tau})\) depends on the control \(\nu\) only through the values of \(\nu\) on the interval \([S, \tau]\). For each \(S \in \mathcal{T}\), let \(\mathcal{V}_S\) be the set of bounded predictable processes \(\nu\) defined on \([S, T]\), such that \(\nu_t > -1, S \leq t \leq T, dP \otimes dt\)-a.s. We thus have

\[
Y(S) = \text{ess sup}_{(\tau,\nu) \in \mathcal{T}_S \times \mathcal{V}_S} \mathcal{E}^{\nu}_{S,\tau}(\xi_{\tau}) \quad \text{a.s.}
\]

**Definition 4.6.** We say that a family \(X = (X(S), S \in \mathcal{T})\) is admissible if it satisfies the following conditions

In order to facilitate the study of the non-linear problem of control and stopping \((4.3)\), we introduce the following auxiliary non-linear optimal stopping problem: for \(\nu \in \mathcal{V}\), for \(S \in \mathcal{T}\),

\[
Y^\nu(S) = \text{ess sup}_{\tau \in \mathcal{T}_S} \mathcal{E}^{\nu}_{S,\tau}(\xi_{\tau}) \tag{4.4}
\]

We know from [21] that the value family \((Y^\nu(S))_{S \in \mathcal{T}}\) of the auxiliary optimal stopping problem can be aggregated by an optional process \((Y^\nu_t)_{t \in [0,T]} \in \mathbb{S}^2\) which is a strong \(\mathcal{E}^{\nu}\)-supermartingale.

From the definitions and Remark 4.5, we have, for all \(S \in \mathcal{T}\),

\[
Y(S) = \text{ess sup}_{\nu \in \mathcal{V}} Y^\nu_S = \text{ess sup}_{\nu \in \mathcal{V}_S} Y^\nu_S \quad \text{a.s.} \tag{4.5}
\]

Let us note also that \(Y(S) \geq Y^0_S\) a.s., as \(0 \in \mathcal{V}\). Moreover, since \(|\xi_t| \leq V^x,\psi_t, 0 \leq t \leq T\) a.s. it follows that for all \(S \in \mathcal{T}\), \(\tau \in \mathcal{T}_S\) and \(\nu \in \mathcal{V}\), \(\mathcal{E}^{\nu}_{S,\tau}(|\xi_{\tau}|) \leq \mathcal{E}^{\nu}_{S,\tau}(V^x,\psi_{\tau}) = V^x,\psi_S \quad \text{a.s.}
\]

Hence, taking the essential supremum over \(\tau \in \mathcal{T}_S\) and \(\nu \in \mathcal{V}\) in this inequality, we derive that \(Y(S) \leq V^x,\psi_S\) a.s. Since \(Y^0 \in \mathbb{S}^2\) and \(V^x,\psi \in \mathbb{S}^2\), it follows that \(E[\text{ess sup}_{S \in \mathcal{T}} Y(S)^2] < +\infty\).

**Lemma 4.7.** (admissibility) The value family \((Y(S))_{S \in \mathcal{T}}\) of the non-linear problem of control and stopping is an admissible family, that is,

1. For all \(S \in \mathcal{T}\), \(Y(S)\) is a real-valued \(\mathcal{G}_S\)-measurable random variable.
2. For all \(S, S' \in \mathcal{T}\), \(Y(S) = Y(S')\) a.s. on \(\{S = S'\}\).
Proof. By definition (4.5), for each $S \in \mathcal{T}$, $Y(S)$ is $\mathcal{G}_S$-measurable as the essential supremum of $\mathcal{G}_S$-measurable random variables. Let $S, S' \in \mathcal{T}$ be such that $S = S'$ a.s. We have $Y^\nu_S = Y^\nu_{S'}$ a.s. for all $\nu \in \mathcal{V}$. Hence, $\text{ess sup}_{\nu \in \mathcal{V}} Y^\nu_S = \text{ess sup}_{\nu \in \mathcal{V}} Y^\nu_{S'}$ a.s. From this, together with (4.5), we get $Y(S) = Y(S')$ a.s. The admissibility of the value family is thus proven.

Proposition 4.8. (Maximizing sequence) Let $S \in \mathcal{T}$. There exists a sequence of controls $(\nu^n)_{n \in \mathbb{N}}$ with $\nu^n \in \mathcal{V}_S$, for all $n$, such that the sequence $(Y^\nu_S)^n_{n \in \mathbb{N}}$ is non-decreasing and satisfies:

$$Y(S) = \lim_{n \to \infty} Y^\nu_S$$

a.s. (4.6)

Proof. We show that the set $\{Y^\nu_S : \nu \in \mathcal{V}_S\}$ is stable under pairwise maximization. Indeed, let $\nu, \nu' \in \mathcal{V}_S$. Set $A := \{Y^\nu_S \leq Y^\nu'_{S}\}$. We have $A \in \mathcal{F}_S$. Set $\tilde{\nu} := \nu 1_A + \nu' 1_{A^c}$. Then $\tilde{\nu} \in \mathcal{V}_S$. We have $Y^\nu_S 1_A = \text{ess sup}_{\tau \in T_S} \mathcal{E}^\nu_{S,\tau} (\xi_\tau)^1_A = \text{ess sup}_{\tau \in T_S} \mathcal{E}^{\nu'}_{S,\tau} (\xi_\tau)^1_{A} = \text{ess sup}_{\tau \in T_S} \mathcal{E}^{\nu'}_{S,\tau} (\xi_\tau)^1_{A} = \text{ess sup}_{\tau \in T_S} \mathcal{E}^{\nu'}_{S,\tau} (\xi_\tau)^1_{A} \in Y^\nu_S 1_A$ a.s. and similarly on $A^c$. It follows that $Y^\nu_S = Y^\nu_S 1_A + Y^\nu'_{S} 1_{A^c} = Y^\nu'_{S} \in \mathcal{V}_S$ a.s. The result of the proposition follows by a classical result on essential suprema (cf. Neveu (1975)).

Definition 4.9. ($\mathcal{E}^\nu$-(super)martingale family) Let $g$ be a $\lambda$-admissible driver satisfying Assumption 2.2. Let $(X(S), S \in \mathcal{T})$ be an admissible family such that $\mathbb{E}[\text{ess sup}_{S \in \mathcal{T}} (X(S))^2] < \infty$. We say that $(X(S), S \in \mathcal{T})$ is an $\mathcal{E}^\nu$-supermartingale family (resp. $\mathcal{E}^\nu$-submartingale, $\mathcal{E}^\nu$-martingale) family if for all $S, S' \in \mathcal{T}$ such that $S \geq S'$ a.s., $\mathcal{E}^\nu_{S',S}(X(S)) \leq \mathcal{E}^\nu_{S,S}(X(S))$ (resp. $\geq$, $=\mathcal{E}^\nu_{S,S}(X(S))$).

Proposition 4.10. The family $(Y(S))$ satisfies the following properties: $(Y(S))$ is an $\mathcal{E}^\nu$-supermartingale family for all $\nu \in \mathcal{V}$ and $Y(S) \geq \xi_S$ a.s. for all $S \in \mathcal{T}$. Moreover, $(Y(S))$ is the smallest family satisfying these properties.

Proof. For all $S \in \mathcal{T}$, for all $\nu \in \mathcal{V}_S$, $Y^\nu_S \geq \xi_S$ a.s. Hence, for all $S \in \mathcal{T}$, $Y(S) \geq \xi_S$ a.s. Let $S, S' \in \mathcal{T}$ be such that $S \geq S'$ a.s. By Proposition 4.8, there exists a sequence of controls $(\nu^n)_{n \in \mathbb{N}}$, with $\nu^n \in \mathcal{V}_S$ for all $n$, such that $Y(S) = \lim_{n \to \infty} Y^\nu_S$ a.s. Let $\nu \in \mathcal{V}$. By the continuity property of $\mathcal{E}^\nu$ with respect to terminal condition, we have $\mathcal{E}^\nu_{S',S}(Y(S)) = \lim_{n \to \infty} \mathcal{E}^\nu_{S',S}(Y^{\nu^n}_S)$ a.s. For each $n$, we set $\tilde{\nu}^n := \nu^n 1_{[S',S]}(t) + \nu^n 1_{[S,S]}(t)$. We note that $\tilde{\nu}^n \in \mathcal{V}_S$; hence, $f^{\tilde{\nu}^n}$ is $\lambda$-admissible. We have $f^{\tilde{\nu}^n} = f^n 1_{[S',S]} + f^{\nu^n} 1_{[S,S]}$. Moreover, $Y^\nu_{S'} = Y^\nu_{S'}$ (as $f^{\tilde{\nu}^n} = f^{\nu^n}$ on $[S,T]$).

From these observations, we deduce

$$\mathcal{E}^\nu_{S',S}(Y^{\nu^n}_S) = \mathcal{E}^\nu_{S',S}(Y^\nu_{S'}) \leq Y^\nu_{S'},$$

where the (last) inequality is due to the fact that $Y^\nu_{S'}$ is a strong $\mathcal{E}^\nu$-supermartingale. We thus get $\mathcal{E}^\nu_{S',S}(Y(S)) = \lim_{n \to \infty} \mathcal{E}^\nu_{S',S}(Y^{\nu^n}_S) \leq \inf_{n \to \infty} Y^\nu_{S'} \leq Y(S')$ a.s., where the last inequality follows from (4.5). As $\nu \in \mathcal{V}$ is arbitrary, we conclude that the family $(Y(S))$ is an $\mathcal{E}^\nu$-supermartingale family for all $\nu \in \mathcal{V}$.

Let us prove the second statement. Let $(Y'(S), S \in \mathcal{T})$ be an admissible family satisfying the properties: $(Y'(S))$ is an $\mathcal{E}^\nu$-supermartingale family for all $\nu \in \mathcal{V}$ and $Y'(S) \geq \xi_S$ a.s. for all $S \in \mathcal{T}$. Let $\nu \in \mathcal{V}$. By the properties of $Y'$, for all $S \in \mathcal{T}$, for all $\tau \in T_S$, $Y'(S) \geq \mathcal{E}^\nu_{S,S}(Y'(\tau)) \geq \mathcal{E}^\nu_{S,S}(\xi_S)$ a.s. By taking the essential supremum over $\tau \in T_S$ and $\nu \in \mathcal{V}$, we get $Y'(S) \geq Y(S)$ a.s.
**Corollary 4.11.** There exists an r.u.s.c. process \((Y_t) \in S^2\) which aggregates the value family \((Y(S))\) of the problem of control and stopping (4.3). The process \((Y_t)\) is a strong \(\mathcal{E}\nu\)-supermartingale for all \(\nu \in \mathcal{V}\) and \(Y_t \geq \xi_t\), for all \(t \in [0, T]\), a.s. Moreover, the process \((Y_t)\) is the smallest process in \(S^2\) satisfying these properties.

**Proof.** The above Proposition 4.10 implies in particular that the value family \((Y(S))\) is a strong \(\mathcal{E}_0\)-supermartingale family. By Lemma A.1 in [23], there exists an r.u.s.c. process \((Y_t)\) in \(S^2\) aggregating the family \((Y(S))\). The other properties of the aggregating process \((Y_t)\) follow directly from Proposition 4.10. \(\square\)

**Corollary 4.12 (The right-continuous case).** Assume moreover that the process \((\xi_t)\) in problem (4.3) is RCLL. Then, the process \((Y_t)\) is RCLL. Moreover, \((Y_t)\) is the smallest RCLL process in \(S^2\) satisfying the properties: for each \(\nu \in \mathcal{V}\), \((Y_t)\) is a (strong) RCLL \(\mathcal{E}\nu\)-supermartingale greater than or equal to \((\xi_t)\).

**Proof.** This result follows directly from Corollary 4.11, together with Remark A.7 in [23]. \(\square\)

### 4.2 The strict value family \((Y^+(S))\)

Let \(S\) be a stopping time in \(\mathcal{T}_0\). We denote by \(\mathcal{T}_{S^+}\) the set of stopping times \(\theta \in \mathcal{T}_0\) with \(\theta > S\) a.s. on \(\{S < T\}\) and \(\theta = T\) a.s. on \(\{S = T\}\). The strict value \(Y^+(S)\) (at time \(S\)) is defined by

\[
Y^+(S) := \text{ess sup}_{(\tau, \nu) \in \mathcal{T}_{S^+} \times \mathcal{V}} \mathcal{E}_S^\nu(\xi_{\tau}). \tag{4.7}
\]

We note that (as for \((Y(S))\)) the set \(\mathcal{V}\) in the above problem can be replaced with the set \(\mathcal{V}_S\) without changing the value of the problem. We note also that \(Y^+(S) = \xi_T\) a.s. on \(\{S = T\}\).

Let \(S\) be a stopping time in \(\mathcal{T}_0\) and let \(\nu \in \mathcal{V}\). We introduce the following auxiliary (strict) optimal stopping problem (to be compared with (4.4)):

\[
Y^{\nu,+}(S) := \text{ess sup}_{\tau \in \mathcal{T}_{S^+}} \mathcal{E}_S^\nu(\xi_{\tau}). \tag{4.8}
\]

We know from [21] (cf. Proposition 9.1) that there exists a strong \(\mathcal{E}\nu\)-supermartingale, denoted by \((Y^{\nu,+}_t)\), which aggregates the value family \((Y^{\nu,+}(S))\) of the above (strict) optimal stopping problem. Note that we have

\[
Y^+(S) = \text{ess sup}_{\nu \in \mathcal{V}} Y^{\nu,+}_S = \text{ess sup}_{\nu \in \mathcal{V}_S} Y^{\nu,+}_S \text{ a.s.} \tag{4.9}
\]

Using the above representation and the same type of arguments as those used above for the value family \((Y(S))_{S \in \mathcal{T}_0}\), we show that the strict value family \((Y^+(S))_{S \in \mathcal{T}_0}\) is an admissible family, satisfying the integrability condition \(\mathbb{E}\left[\text{ess sup}_{S \in \mathcal{T}_0} (Y^+(S))^2\right] < \infty\) and the following properties:
Proposition 4.13. For each $S \in \mathcal{T}_0$, there exists a maximizing sequence $(\nu^n) = (\nu^n(S)) \in \mathcal{V}_S^n$ for the optimal control problem from equation (4.9), that is, $Y_{S}^{+} = \lim_{n \to \infty} \uparrow Y_{S}^{\nu_n, +}$ a.s.

Proposition 4.14. The family $(Y^{+}(S))_{S \in \mathcal{T}_0}$ is an $\mathcal{E}^{\nu}$-supermartingale family for each $\nu \in \mathcal{V}$.

As above, we deduce the following

Corollary 4.15. There exists a process $(Y_t^+) \in \mathbb{S}^2$ which aggregates the strict value family $(Y^{+}(S))_{S \in \mathcal{T}_0}$. The process $(Y_t^+)$ is a strong $\mathcal{E}^{\nu}$-supermartingale for all $\nu \in \mathcal{V}$.

Moreover, the following result holds true. The result is based on the representation (4.9) and on properties of the strict value process $(Y_t^{\nu, +})$ of the auxiliary optimal stopping problem (4.8).

We recall that $(Y_{t+})$ denotes the process of right limits of the process $(Y_t)$. We recall also that $(Y_{t+})$ is well-defined as $(Y_t)$ is a strong $\mathcal{E}^{\nu}$-supermartingale, and hence, has right (and left) limits.

We recall that $(Y_t^{\nu, +})$ denotes the process of right limits of the process $(Y_t^{\nu})$.

Theorem 4.16. (i) The strict value process $(Y_t^+)$ is right-continuous.

(ii) For all $S \in \mathcal{T}_0$, $Y_{S}^{+} = Y_{S+}$ a.s. (in other words, the strict value process $(Y_t^+)$ coincides with the process of right limits $(Y_{t+})$).

(iii) For all $S \in \mathcal{T}_0$, $Y_S = Y_{S+} \vee \xi_S$ a.s.

We have the following intermediary result:

Proposition 4.17. For all $S \in \mathcal{T}_0$,

$$\mathbb{E}[Y_S^{+}] = \sup_{\nu \in \mathcal{V}} \mathbb{E}[Y_{S}^{\nu, +}]$$

Proof. From the representation (4.9), we deduce $\mathbb{E}[Y_S^{+}] = \mathbb{E}[\text{ess sup}_{\nu \in \mathcal{V}} Y_{S}^{\nu, +}] \geq \sup_{\nu \in \mathcal{V}} \mathbb{E}[Y_{S}^{\nu, +}]$. We now show the converse inequality. By Proposition 4.13, there exists a sequence $(\nu_n) = (\nu_n(S))$ in $\mathcal{V}_S^n$ such that $Y_{S}^{+} = \lim_{n \to \infty} \uparrow Y_{S}^{\nu_n, +}$. We thus have $\mathbb{E}[Y_S^{+}] = \mathbb{E}[\lim_{n \to \infty} \uparrow Y_{S}^{\nu_n, +}] = \lim_{n \to \infty} \uparrow \mathbb{E}[Y_{S}^{\nu_n, +}]$, where we have used dominated convergence to exchange limit and expectation. For all $n$, we have $\mathbb{E}[Y_{S}^{\nu_n, +}] \leq \sup_{\nu \in \mathcal{V}} \mathbb{E}[Y_{S}^{\nu, +}]$. We conclude that $\mathbb{E}[Y_S^{+}] \leq \sup_{\nu \in \mathcal{V}} \mathbb{E}[Y_{S}^{\nu, +}]$. The proposition is thus proved.

We are now ready to prove Theorem 4.16.

Proof of Theorem 4.16. To prove statement (i), we first show that the process $(Y_t^+)$ is right-lowersemicontinuous along stopping times in expectation. Let $S \in \mathcal{T}_0$, let $(S_n)$ be a non-increasing sequence of stopping times in $\mathcal{T}_S$ with $\lim S_n = S$ a.s. By Proposition 4.17, we have $\mathbb{E}[Y_{S_n}^{+}] = \sup_{\nu \in \mathcal{V}} \mathbb{E}[Y_{S_n}^{\nu, +}]$, for all $n \in \mathbb{N}$. Hence, $\liminf_{n \to \infty} \mathbb{E}[Y_{S_n}^{+}] = \mathbb{E}[\lim_{n \to \infty} \uparrow Y_{S_n}^{\nu, +}] = \mathbb{E}[Y_{S+}^{\nu, +}]$. Thus, $Y_{S+}^{\nu, +}$ is right-lowersemicontinuous along stopping times in expectation.

\[\text{Indeed, each process } \nu \in \mathcal{V}_S \text{ can be seen as a process } \tilde{\nu} \text{ in } \mathcal{V} \text{ by setting } \tilde{\nu} = \nu \text{ on } [S,T] \text{ and } \tilde{\nu} = 0 \text{ on } [0,S).\]
To prove this, we fix \( \nu \in \mathcal{V} \), the process \((Y_{\nu t}^+)\) is right-continuous (cf. Theorem 9.2 in [21]), hence right-continuous along stopping times (cf. [9]); by dominated convergence, we thus have \( \lim \inf_{n \to \infty} \mathbb{E}[Y_{S_n}^{\nu t}^+] = \lim_{n \to \infty} \mathbb{E}[Y_{S_n}^{\nu t}^+] = \mathbb{E}[Y_{S}^{\nu t}^+] \). Hence, \((Y_{\nu t}^+)\) is right-lowersemicontinuous along stopping times, and hence right-uppersemicontinuous along stopping times in expectation (due to its integrability). Hence, \((Y_{\nu t}^+)\) is right-continuous along stopping times in expectation. We deduce that \((Y_{\nu t}^+)\) is right-lowersemicontinuous along stopping times, and hence right-uppersemicontinuous along stopping times in expectation (due to its integrability). Hence, \((Y_{\nu t}^+)\) is right-continuous along stopping times in expectation. We deduce that \((Y_{\nu t}^+)\) is right-continuous (cf. e.g. [10]). We now show (ii). Let \( S \in \mathcal{T}_0 \). One inequality, namely the inequality \( Y_{S}^+ \geq Y_S^+ \) a.s., follows from the right-continuity of \((y_{\nu t}^+)\), established in (i). Indeed, let \((S_n)\) be a non-increasing sequence of stopping times in \( \mathcal{T}_{S} \) with \( \lim \downarrow S_n = S \) a.s. We know that \( Y_T \geq Y_T^+ \) a.s., for all \( T \in \mathcal{T}_0 \). Hence, \( Y_{S_n} \geq Y_{S_n}^+ \) a.s., for all \( n \). By taking the limit when \( n \to \infty \) and by using the right-continuity of \((y_{\nu t}^+)\), we get \( Y_{S}^+ \geq Y_S^+ \) a.s. For the converse inequality, we first show

\[
\mathcal{E}_{S,S_n}^0(Y_{S_n}) \leq Y_S^+ \quad \text{a.s. for all } n. \tag{4.10}
\]

To prove this, we fix \( n \) and we take \((\tau^p, \nu^p) \in \mathcal{T}_{S} \times \mathcal{V} \) an optimizing sequence for the problem with value \( Y_{S_n} \), i.e. \( Y_{S_n} = \lim_{p \to \infty} \mathcal{E}^{\nu^p}_{S_n, \tau^p}(\xi_{\tau^p}) \). We have

\[
\mathcal{E}_{S,S_n}^0(Y_{S_n}) = \mathcal{E}_{S,S_n}^0(\lim_{p \to \infty} \mathcal{E}^{\nu^p}_{S_n, \tau^p}(\xi_{\tau^p})) = \lim_{p \to \infty} \mathcal{E}_{S,S_n}^0(\mathcal{E}^{\nu^p}_{S_n, \tau^p}(\xi_{\tau^p})) \quad \text{a.s.,} \tag{4.11}
\]

where we have used the continuity property of \( \mathcal{E}_{S,S_n}^0(\cdot) \) with respect to the terminal condition (recall that here \( n \) is fixed). We set \( \tilde{\nu}^p := \nu^p \mathbb{1}_{\{t > S_n\}} \) (hence, \( \tilde{\nu}^p = 0 \) on \( \{t \leq S_n\} \)). We note that \( \tilde{\nu} \in \mathcal{V} \). Using the definition of \( \tilde{\nu} \) and the consistency property of \( \mathcal{E} \)-expectations, we get \( \mathcal{E}_{S,S_n}^0(\mathcal{E}^{\nu^p}_{S_n, \tau^p}(\xi_{\tau^p})) = \mathcal{E}^{\tilde{\nu}^p}_{S, \tau^p}(\xi_{\tau^p}) \leq Y_S^+ \quad \text{a.s.} \) (where for the inequality we have used that \( \tau^p \in \mathcal{T}_{S} \)). From this, together with equation (4.11), we derive the desired inequality (4.10). From (4.10) and using the continuity of \( \mathcal{E} \)-expectations with respect to the terminal time and the terminal condition, we derive \( Y_S^+ \geq \lim_{n \to \infty} \mathcal{E}_{S,S_n}^0(Y_{S_n}) = \mathcal{E}_{S,S}^0(Y_{S}^+) = Y_S^+ \) a.s. Hence, \( Y_S^+ \geq Y_S^+ \) a.s., which, together with the previously shown converse inequality, proves the equality.

We now show (iii). Using successively statement (ii), relation (4.9), Theorem 9.2 (iii) in [21], and relation (4.5), we get

\[
Y_{S_n} \lor \xi = Y_S^+ \lor \xi = \text{ess sup}_{\nu \in \mathcal{V}} \left( Y_S^+ \lor \xi \right) = \text{ess sup}_{\nu \in \mathcal{V}} Y_S^\nu = Y_S \quad \text{a.s.} \quad \square
\]

### 4.3 Proof of the dual representation

We will now provide a dual representation for the seller’s superhedging price \( u_0 \) in terms of the value (at time 0) of the non-linear problem of control and stopping studied above. We also give a superhedging strategy for the seller. From this result, we will deduce the dual representation (in terms of the \( f \)-martingale probability measures) stated in Theorem 4.1.

To this aim, we first give the following lemma.
Lemma 4.18. ($\mathcal{E}^f$-optional decomposition of the value process $Y$) There exists a unique $Z \in \mathbb{H}^2$, a unique $C \in \mathbb{C}^2$ and a unique nondecreasing optional RCLL process $h$, with $h_0 = 0$ and $E[h_T^2] < \infty$ such that

$$Y_t = Y_0 - \int_0^t f(s, Y_s, Z_s)ds + \int_0^t \sigma_s^{-1}(\sigma_s dW_s + \beta_s dM_s) - h_t - C_t, \quad 0 \leq t \leq T \quad \text{a.s.} \quad (4.12)$$

Proof. By Corollary 4.11, the value process $Y$ is the smallest process in $\mathbb{S}^2$, which is a strong $\mathcal{E}^\nu$-supermartingale for all $\nu \in V$ such that $Y_t \geq \xi_t$, for all $t \in [0, T]$, a.s. The desired result then follows from the non-linear optional decomposition of strong $\mathcal{E}^\nu$-supermartingales for all $\nu \in V$ (cf. Theorem B.4 in [23]). \qed

Theorem 4.19. The superhedging price $u_0$ of the American option is equal to the value $Y_0$ (at time 0) of the non-linear problem of control and stopping (4.3), that is

$$u_0 = \sup_{(\tau, \nu) \in T \times V} \mathcal{E}^\nu_{0, \tau}(\xi_\tau). \quad (4.13)$$

Moreover, the portfolio strategy $\varphi^* := \sigma^{-1}Z$, where the process $Z$ is the one from the $\mathcal{E}^f$-optional decomposition of the value process $Y$ from Lemma 4.18, is a superhedging strategy for the seller, that is, $\varphi^* \in \mathcal{A}(u_0)$.

Proof. Let $\mathcal{H}$ be the set of initial capitals which allow the seller to be “superhedged”, that is $\mathcal{H} = \{x \in \mathbb{R} : \exists \varphi \in \mathcal{A}(x)\}$. From the definition of $u_0$ (see (3.6)), we have $u_0 = \inf \mathcal{H}$. We first show that

$$u_0 \geq \sup_{(\tau, \nu) \in T \times V} \mathcal{E}^\nu_{0, \tau}(\xi_\tau). \quad (4.14)$$

Let $x \in \mathcal{H}$. There thus exists $\varphi \in \mathcal{A}(x)$, which implies that for each $\tau \in T$, we have $V^x_{\tau, \varphi} \geq \xi_\tau$ a.s. Let $\nu \in V$. By taking the $\mathcal{E}^\nu$-evaluation in the above inequality, using the monotonicity of $\mathcal{E}^\nu$ and the $\mathcal{E}^\nu$-martingale property of the wealth process $V^x_{\tau, \varphi}$, we obtain $x = \mathcal{E}^\nu_{0, \tau}(V^x_{\tau, \varphi}) \geq \mathcal{E}^\nu_{0, \tau}(\xi_\tau)$. By arbitrariness of $\tau \in T$ and $\nu \in V$, we get $x \geq \sup_{(\tau, \nu) \in T \times V} \mathcal{E}^\nu_{0, \tau}(\xi_\tau)$, which holds for all $x \in \mathcal{H}$. By taking the infimum over $x \in \mathcal{H}$, we obtain the desired inequality (4.14). Since, by definition of $Y_0$, we have $Y_0 = \sup_{(\tau, \nu) \in T \times V} \mathcal{E}^\nu_{0, \tau}(\xi_\tau)$, the inequality (4.14) can be written $u_0 \geq Y_0$.

We now show the converse inequality, that is, $Y_0 \geq u_0$. Since $u_0 = \inf \mathcal{H}$, it is sufficient to show that the portfolio strategy $\varphi^* := \sigma^{-1}Z$ is a superhedging strategy for the seller associated with the initial capital $Y_0$, that is, satisfies

$$\varphi^* \in \mathcal{A}(Y_0). \quad (4.15)$$

We consider the portfolio associated with the initial capital $Y_0$ and the strategy $\varphi^*$. By (3.2)-(3.3), the value of this portfolio $(V_t^{Y_0, \varphi^*})$ satisfies the following forward equation:

$$V_t^{Y_0, \varphi^*} = Y_0 - \int_0^t f(s, V_s^{Y_0, \varphi^*}, Z_s)ds + \int_0^t \sigma_s^{-1}Z_s(\sigma_s dW_s + \beta_s dM_s), \quad 0 \leq t \leq T \quad \text{a.s.} \quad (4.16)$$
Moreover, by the optional $\mathcal{E}^f$-decomposition of the value process $(Y_t)$ (cf. Lemma 4.18), the process $(Y_t)$ satisfies the forward SDE (4.12). Since $(h_t)$ and $(C_t)$ are nondecreasing, by the comparison result for forward differential equations, we thus get $V_t^{Y_0,\varphi^*} \geq Y_t$, $0 \leq t \leq T$ a.s. Hence, since $Y_t \geq \xi_t$, we get $V_t^{Y_0,\varphi^*} \geq \xi_t$, $0 \leq t \leq T$ a.s., which implies the desired property (4.15). We thus derive that $Y_0 \in \mathcal{H}$, and hence that $Y_0 \geq u_0$. Since $Y_0 \leq u_0$, we deduce the equality $Y_0 = u_0$. Moreover, by (4.15), we derive that $\varphi^* \in A(u_0)$, which completes the proof.

Remark 4.20. From a financial point of view, the process $(h_t)$ from equation (4.12) can be interpreted as the cumulative amount the seller withdraws from the hedging portfolio up to time $t$. More precisely, for each time $t$, the seller can withdraw the amount $dh_t$ from his/her portfolio between $t$ and $t + dt$. In particular, at time $\tau$, the seller can withdraw the amount $\Delta h_\tau$ from his/her portfolio, which, by equation (4.12), is equal to

$$\Delta h_\tau = \beta_\tau \sigma^{-1}_t Z_\tau - \Delta Y_\tau \quad \text{a.s.}$$

The term $\beta_\tau \sigma^{-1}_t Z_\tau = \beta_\tau \varphi^*_\tau$ represents the jump at the default time $\tau$ of the amount invested in the risky asset $S$ (which is equal to the jump of the value of the portfolio). Note that in this case, the value of the hedging portfolio, denoted by $(V_t^{Y_0,\varphi^*,h})$, taking into account these withdrawals, satisfies

$$dV_t^{Y_0,\varphi^*,h} = -f(t, V_t^{Y_0,\varphi^*,h}, \sigma_t \varphi^*_t)dt + \varphi^*_t (\sigma_t dW_t + \beta_t dM_t) - dh_t; \quad V_0^{Y_0,\varphi^*,h} = Y_0.$$

We thus have $V_t^{Y_0,\varphi^*} = V_t^{Y_0,\varphi^*,0}$.

Proof of Theorem 4.1: The proof follows from the previous theorem 4.19 and from Remark 4.4. Indeed, under the additional integrability condition $\psi \in \cap_{\nu \in \mathcal{V}} \mathbb{H}^2_{\mathcal{Q}^\nu}$ on the process $\psi$ from Assumption (4.1), by Remark 4.4, the above dual representation of the superhedging price can be written in terms of the $f$-martingale probability measures (characterized in Proposition 3.5), that is

$$u_0 = \sup_{(\tau, \nu) \in \mathcal{T} \times \mathcal{V}} \mathcal{E}^f_{\mathcal{Q}^\nu,0,\tau}(\xi_\tau),$$

which ends the proof of Theorem 4.1. □

5 Infinitesimal characterizations of the seller’s superhedging price process

We now introduce the seller’s (superhedging) price of the American option at each time/stopping time $S \in \mathcal{T}$. We first define, for each initial wealth $X \in L^2(\mathcal{G}_S)$, a superhedging strategy as a portfolio strategy $\varphi \in \mathbb{H}^2$ such that $V_t^{S,X,\varphi} \geq \xi_t$ for all $t \in [0, T]$ a.s., where $V_t^{S,X,\varphi}$ denotes the wealth process associated with initial time $S$ and initial condition $X$. Let $\mathcal{A}_S(X)$ be the
set of all superhedging strategies associated with initial time $S$ and initial wealth $X$. The seller’s (superhedging) price at time $S$ is defined by the random variable

$$u(S) := \text{ess inf}\{X \in L^2(G_S), \exists \varphi \in \mathcal{A}_S(X)\}.$$ 

Using Lemma 4.18 and similar arguments to those used in the proof of Theorem 4.19, one can show that for each $S \in \mathcal{T}$, we have $u(S) = Y_S$ a.s. We call $(Y_t)$ the seller’s (superhedging) price process of the American option.

**Definition 5.1.** Let $\xi \in \mathbb{S}^2$. A process $Y' \in \mathbb{S}^2$ is said to be a supersolution of the constrained reflected BSDE with driver $f$ and obstacle $\xi$ if there exists a process $(Z', K', A', C') \in \mathbb{H}^2 \times \mathbb{H}^1_\lambda \times \mathcal{A}^2 \times \mathbb{C}^2$ such that

$$-dY'_t = f(t, Y'_t, Z'_t)dt + dA'_t + dC'_{t-} - Z'_tdW_t - K'_tdM_t;$$

$$Y'_T = \xi_T \text{ a.s. and } Y'_t \geq \xi_t \text{ for all } t \in [0, T] \text{ a.s.;}$$

$$(Y'_t - \xi_t)(C'_t - C'_{t-}) = 0 \text{ a.s. for all } \tau \in \mathcal{T}_0;$$

$$A' + \int_0^t (K'_s - \beta_s\sigma_s^{-1}Z'_s)\lambda_s ds \in \mathcal{A}^2 \text{ and } (K'_t - \beta_t\sigma_t^{-1}Z'_t)\lambda_t \leq 0, \text{ } t \in [0, T], \text{ } dP \otimes dt - \text{a.e.};$$

(5.4)

**Remark 5.2.** This definition can be extended to the case of a general driver $g$ (which may depend also on $k$).

Equation (5.3) is referred to as Skorokhod condition for the process $C'$.

**Remark 5.3.** The process $A'$ can be uniquely decomposed as the sum of two nondecreasing processes $B'$ and $\hat{B}$ belonging to $\mathcal{A}^2$ with $dB'_t \perp d\hat{B}_t,$ such that $B'$ satisfies the Skorokhod condition, that is

$$\int_0^t (Y'_{s-} - \xi_{s-})dB'_s = 0 \text{ a.s.}$$

(5.5)

Note that the processes $B'$ and $\hat{B}$ are given by $B'_t = \int_0^t 1_{\{Y'_{s-} = \xi_{s-}\}}dA'_s$ and $\hat{B}_t = \int_0^t 1_{\{Y'_{s-} > \xi_{s-}\}}dA'_s$ for all $t \in [0, T]$. It follows that $Y' \in \mathbb{S}^2$ is a supersolution of the constrained reflected BSDE with driver $f$ and obstacle $\xi$ if and only if there exists a process $(Z', K', B', \hat{B}, C') \in \mathbb{H}^2 \times \mathbb{H}^1_\lambda \times \mathcal{A}^2 \times \mathcal{A}^2 \times \mathbb{C}^2$ such that

$$-dY'_t = f(t, Y'_t, Z'_t)dt + dB'_t + d\hat{B}_t + dC'_{t-} - Z'_tdW_t - K'_tdM_t;$$

$$Y'_T = \xi_T \text{ a.s. and } Y'_t \geq \xi_t \text{ for all } t \in [0, T] \text{ a.s.;}$$

$$(Y'_t - \xi_t)(C'_t - C'_{t-}) = 0 \text{ a.s. for all } \tau \in \mathcal{T}_0;$$

$$\int_0^t (Y'_{s-} - \xi_{s-})dB'_s = 0 \text{ a.s. and } d\hat{B}_t \perp dB'_t,$$

(5.9)

$7$in the sense of Definition 2.3 from [12]
and such that the constraints (5.4) hold, with $A'$ replaced by $B' + \hat{B}$.

In the particular case when $\hat{B} = 0$, since $B'$ satisfies the Skorokhod condition, the process $(Y', Z', K', B', C')$ is thus a solution of the reflected BSDE (with irregular obstacle $(\xi_t)$), here with the additional constraints (5.4). Thus, when passing from the notion of a solution of the reflected BSDE to the notion of a supersolution of the reflected BSDE, there appears an additional nondecreasing predictable process $\hat{B}$, which increases only when $Y'_{t-} > \xi_{t-}$.

**Theorem 5.4.** (Infinitesimal characterization I) The seller’s price process $(Y_t)$ is a supersolution of the constrained reflected BSDE associated with driver $f$ and obstacle $\xi$ from Definition 5.1, that is, there exists a unique process $(Z, K, A, C) \in \mathbb{H}^2 \times \mathbb{H}_1^2 \times \mathcal{A}^2 \times \mathbb{C}^2$ such that $(Y, Z, K, A, C)$ satisfies Definition 5.1. Moreover, it is the minimal one, that is, if $(Y'_t)$ is another supersolution, then $Y'_t \geq Y_t$ for all $t \in [0, T]$ a.s.

Moreover, the portfolio strategy $\varphi^\ast := \sigma^{-1}Z$ is a superhedging strategy for the seller, that is, $\varphi^\ast \in \mathcal{A}(u_0)$.

**Remark 5.5.** Suppose here that there is no default in the market. In this case, the filtration $\mathcal{G}$ is the one associated with the Brownian motion $W$, and in the dynamics of the price process $(S_t)$ and of the wealth process $(V_t)$, $M = 0$ and $\beta = 0$. Hence, the market is complete, and we have $\mathcal{V} = \{0\}$. From this observation, we derive that for each $S \in \mathcal{T}$, $\Delta_{t\tau}Y_S = Y_S^0 = \text{ess sup}_{\tau \in T_\tau} \mathcal{E}_{\tau}^0(\xi_\tau)$ a.s. By Theorem 6.7 in [22], $(Y_t)$ is thus the solution of the reflected BSDE associated with driver $f$ and irregular obstacle $(\xi_t)$. In other words, there exists $(Z, K, B, C) \in \mathbb{H}^2 \times \mathbb{H}_1^2 \times \mathcal{A}^2 \times \mathbb{C}^2$ such that equations (5.6) to (5.9) hold with $\hat{B} = 0$.

Proof. Since $Y$ is the value process, we have $Y_T = \xi_T$ a.s. and $Y_t \geq \xi_t$ for all $t \in [0, T]$ a.s. Moreover, by Corollary 4.11, the value process $Y$ is a strong $\mathcal{F}^\nu$-supermartingale for all $\nu \in \mathcal{V}$. Hence, by the non-linear predictable decomposition (cf. Proposition B.1 in [23]), there exists a unique process $(Z, K, A, C) \in \mathbb{H}^2 \times \mathbb{H}_1^2 \times \mathcal{A}^2 \times \mathbb{C}^2$ such that equation (5.1) and the conditions (5.4) hold. We now show that the process $C$ satisfies the Skorokhod condition (5.3). Let $\tau \in \mathcal{T}_0$. By Theorem 4.16 (iii), we have $Y_{t\tau} = Y_{t\tau} + \xi_{t\tau}$ a.s.. Hence, $\Delta_+ \Delta_+ Y_{t\tau} = 1_{\{Y_{t\tau} = \xi_{t\tau}\}} \Delta_+ Y_{t\tau}$ a.s. On the other hand, since $(Y, Z, K, A, C)$ satisfies equation (5.1), we have $\Delta C_{t\tau} = -\Delta_+ Y_{t\tau}$ a.s. We conclude that $\Delta C_{t\tau} = 1_{\{Y_{t\tau} = \xi_{t\tau}\}} \Delta C_{t\tau}$ a.s. Hence, the Skorokhod condition (5.3) is satisfied.

It remains to show that $(Y_t)$ is the minimal supersolution of the constrained reflected BSDE from Definition 5.1. Let $Y'$ be another supersolution of this constrained reflected BSDE and let $(Z', K', A', C')$ be the associated process (from the definition of a supersolution). We have $Y'_{t} \geq \xi_t$ for all $t \in [0, T]$ a.s. Let now $\nu \in \mathcal{V}$. Let $A'^\nu$ be the process defined by

$$A'^\nu := A'_t - \int_0^t (K'_s - \beta_s \sigma_s^{-1}Z'_s)\nu_s \lambda_s ds, \quad 0 \leq t \leq T.$$ 

Since $\nu \in \mathcal{V}$, we have $\nu_t + 1 > 0$ d$P$ $\otimes$ dt-a.s. This together with the second condition from (5.4) imply that $(K'_t - \beta_0 \sigma_t^{-1}Z'_t)\lambda_t (1 + \nu_t) \leq 0$ d$P$ $\otimes$ dt-a.s. Then, using the first condition

---

8In the sense from Definition 2.3 in [22], which, in the case of a right-continuous obstacle, corresponds to the well-known notion of a solution of a reflected BSDE)
from (5.4) (and the definition of $A''$), we obtain that the process $A''$ is nondecreasing. On the other hand, since $(Y', Z', K', A', C')$ satisfies the dynamics from Definition 5.1, we have

$$-dY'_t = (f(t, Y'_t, Z'_t) + (K'_t - \beta_t\sigma_t^{-1}Z'_t)\lambda_t)dt + dA''_t + dC'_{t-} - Z'_tdW_t - K'_tdM_t.$$ 

Hence, by the $\mathcal{E}^g$-Mertens decomposition of strong $\mathcal{E}^g$-supermartingales, applied with the driver $g := f''$ (cf. Theorem 5.1 in [20], or Theorem 7.1 in [21]), we derive that the process $Y''$ is a strong $\mathcal{E}^g$-supermartingale. Since this holds for all $\nu \in \mathcal{V}$, we derive from Corollary 4.11 that $Y'_t \geq Y_t$, for all $t \in [0, T]$ a.s. \hfill \Box

**Remark 5.6.** This result can be extended to any $\lambda$-admissible driver (depending also on $k$).

**Definition 5.7.** Let $\xi \in \mathcal{S}^2$. A process $Y'' \in \mathcal{S}^2$ is called a supersolution of the optional reflected BSDE associated with driver $f$ and obstacle $\xi$ if there exist $Z' \in \mathcal{L}^2$, $C' \in \mathcal{C}^2$ and a nondecreasing optional RCLL process $h'$, with $h'_0 = 0$ and $E[(h'_T)^2] < \infty$ such that

$$-dY'_t = f(t, Y'_t, Z'_t)dt - Z'_t\sigma'_t^{-1}(\sigma_t dW_t + \beta_t dM_t) + dC'_{t-} + dh'_t;$$

$$Y'_T = \xi_T$$

and $Y'_t \geq \xi_t$ for all $t \in [0, T]$ a.s. ;

$$(Y'_t - \xi_t)(C'_t - C'_{t-}) = 0$ a.s. for all $\tau \in \mathcal{T}_0.$$

**Remark 5.8.** We call the above equation an optional reflected BSDE because the associated non decreasing right-continuous process is optional but not necessarily predictable contrary the reflected BSDEs considered in the literature.

Note also that when the obstacle $\xi$ is right-continuous, the purely discontinuous non decreasing process $C''$ (corresponding to the right-jumps of $Y'$) is equal to 0.

From the non-linear optional decomposition (cf. Theorem B.4 in [23]), together with the equivalence of the non-linear predictable and the non optional decompositions (cf. Proposition B.5. in [23]), we derive the following result:

**Theorem 5.9.** (Infinitesimal characterization II) The seller’s superhedging price $(Y_t)$ of the American option is a supersolution of the optional reflected BSDE from Definition 5.7. Moreover, it is the minimal one, that is, if $(Y'_t)$ is another supersolution, then $Y'_t \geq Y_t$ for all $t \in [0, T]$ a.s.

### 6 Duality for the buyer’s superhedging price

**Theorem 6.1** (Duality for the buyer’s superhedging price). Let $(\xi_t) \in \mathcal{S}^2$ be such that Assumption 4.1 is satisfied with $\psi \in \cap_{\nu \in \mathcal{V}} \mathbb{H}^{2}_{Q'}$. Suppose moreover that $(\xi_t)$ is right-continuous and left-uppersemicontinuous along stopping times. The superhedging price for the buyer $\tilde{u}_0$ of the American option satisfies

$$\tilde{u}_0 = \inf_{\nu \in \mathcal{V}} \inf_{\tau \in \mathcal{T}} \sup_{\nu \in \mathcal{V}} \{-\mathcal{E}^{f}_{Q', 0, \tau}(-\xi_{\tau})\} = \sup_{\tau \in \mathcal{T}} \inf_{\nu \in \mathcal{V}} \{-\mathcal{E}^{f}_{Q', 0, \tau}(-\xi_{\tau})\}.$$
Again, to prove Theorem 6.1, we will work under the primitive probability measure $P$.

We define $\tilde{f}(t, \omega, y, z) := -f(t, \omega, -y, -z)$.

Let $\nu \in \mathcal{V}$. We denote by $\mathcal{E}^{\nu}$ or $\tilde{\mathcal{E}}^{\nu}$ the non-linear conditional expectation associated with the $\lambda$-admissible driver

$$\tilde{f}^{\nu}(t, y, z, k) := \tilde{f}(t, y, z) + \nu(t, k - \beta_t \sigma_t^{-1} z).$$

Hence, for each $T' \leq T$ and each $\eta \in L^2(\mathcal{G}_{T'})$, we have $\tilde{\mathcal{E}}^{\nu}_{\lambda}(\eta) = X^{\nu}$ a.s., where $(\tilde{X}^{\nu}, \tilde{Z}^{\nu}, \tilde{K}^{\nu})$ be the unique solution in $S^2 \times \mathbb{H}^2 \times \mathbb{H}^2$ of the BSDE associated with driver $\tilde{f}^{\nu}$, terminal time $T'$ and terminal condition $\eta$.

**Remark 6.2.** Let $\nu \in \mathcal{V}$ and $T' \leq T$. Note that for all $\eta \in L^2(\mathcal{G}_{T'})$, we have $\tilde{\mathcal{E}}^{\nu}_{\lambda}(\eta) = -\mathcal{E}^{\nu}_{\lambda}(-\eta)$, since $f^{\nu}(t, y, z, k) = -f^{\nu}(t, -y, -z, -k)$.

Let $\eta \in L^2(\mathcal{G}_{T'}) \cap L^2(\mathcal{G}_{T'})$. By Remark 4.4, $\tilde{\mathcal{E}}^{\nu}_{\lambda}(\eta) = \mathcal{E}^{f^{\nu}}_{\lambda}(\eta)$. We thus have $\tilde{\mathcal{E}}^{\nu}_{\lambda}(\eta) = -\mathcal{E}^{f^{\nu}}_{\lambda}(\eta)$.

For each $S \in \mathcal{T}$, we define the $\mathcal{F}_S$-measurable random variable $\tilde{Y}(S)$ as follows:

$$\tilde{Y}(S) := \text{ess inf} \sup_{\nu \in \mathcal{V}_S} \text{ess sup} \tilde{\mathcal{E}}^{\nu}_{S, \tau}(\xi_t) \text{ a.s.} \quad (6.1)$$

### 6.1 First properties of the value family $\tilde{Y}$

Let us first show that $E[\text{ess sup}_{\tau \in \mathcal{T}} \tilde{Y}^2(\tau)] < \infty$.

As $0 \in \mathcal{V}$, we have $\tilde{Y}(S) \geq \text{ess sup}_{\tau \in \mathcal{T}_S} \mathcal{E}^{0}_{S, \tau}(\xi_t) = \tilde{Y}^0_\tau$ a.s., where $(\tilde{Y}^0_\tau)$ is the first coordinate of the solution of the reflected BSDE associated with driver $\tilde{f}$ and lower obstacle $(\xi_t)$. Now, since $|\xi_t| \leq V^{x,\psi}_t$, $0 \leq t \leq T$ a.s., we get that for all $S \in \mathcal{T}$, $\tau \in \mathcal{T}_S$ and $\nu \in \mathcal{V}$, $\mathcal{E}^{0}_{S, \tau}(\xi_t) = -\mathcal{E}^{\nu}_{S, \tau}(-\xi_t) \geq -\mathcal{E}^{\nu}_{S, \tau}(\xi_t) \leq -\mathcal{E}^{\nu}_{S, \tau}(\xi_t) = -V^{x,\psi}_t$ a.s. Hence, taking the essential supremum over $\tau \in \mathcal{T}_S$ and then the essential infimum over $\nu \in \mathcal{V}$ in this inequality, we obtain $\tilde{Y}(S) \geq -V^{x,\psi}_S$ a.s.

Since $\tilde{Y}^0 \in S^2$ and $V^{x,\psi} \in S^2$, it follows that $E[\text{ess sup}_{S \in \mathcal{T}} \tilde{Y}(S)^2] < +\infty$.

Using the characterization of the solution of a reflected BSDE with lower obstacle in terms of an optimal stopping problem with $g$-expectations (see Theorem 4.2 in [20] when $(\xi_t)$ is right-u.s.c. payoff), we can rewrite the value function of our problem as follows

$$\tilde{Y}(S) = \text{ess inf}_{\nu \in \mathcal{V}_S} \tilde{Y}^\nu_S = \text{ess inf}_{\nu \in \mathcal{V}} \tilde{Y}^\nu_S,$$

where $\tilde{Y}^\nu$ is the solution of the reflected BSDE associated with driver $\tilde{f}^{\nu}$, obstacle $(\xi_t)_{0 \leq t < T}$ and terminal condition $\xi_T$.

**Proposition 6.3.** (Minimizing sequence) Let $S \in \mathcal{T}$. There exists a sequence of controls $(\nu^n)_{n \in \mathbb{N}}$ with $\nu^n \in \mathcal{V}_S$, for all $n$, such that the sequence $(\tilde{Y}^\nu_S)^n_{n \in \mathbb{N}}$ is non-increasing and satisfies:

$$\tilde{Y}(S) = \lim_{n \to \infty} \downarrow \tilde{Y}^\nu_S \text{ a.s.} \quad (6.3)$$
Lemma 6.5. For all \( \nu \in \mathcal{V}_S \) the set \( \{ \tilde{Y}^\nu_S, \nu \in \mathcal{V}_S \} \) is stable under pairwise maximization. The result of the proposition follows by a classical result on essential suprema/infima (cf. Neveu (1975)). \( \square \)

**Proposition 6.4.** (Aggregation) Let \( (\xi_i) \in S^2 \) (without any regularity assumption). There exists an r.u.s.c. process \( (\tilde{Y}_t) \in S^2 \) which aggregates the value family \( (\tilde{Y}(S)) \) of the problem of control and stopping \mbox{(6.1)}.

The proof of the proposition uses the following lemma.

**Lemma 6.5.** For all \( S \in \mathcal{T}_0 \),

\[
E[\tilde{Y}(S)] = \inf_{\nu \in \mathcal{V}} E[\tilde{Y}^\nu_S].
\]

Proof. From the representation (6.2), we deduce \( E[\tilde{Y}(S)] = E[\text{ess inf}_{\nu \in \mathcal{V}} \tilde{Y}^\nu_S] \leq \inf_{\nu \in \mathcal{V}} E[Y^\nu_S]. \)

We now show the converse inequality. By Proposition 6.3, there exists a sequence of controls \( (\nu_n) = (\nu_n(S)) \in \mathcal{V}_S \) such that \( \tilde{Y}(S) = \lim_{n \to \infty} \downarrow \tilde{Y}^{\nu_n}_S \). We thus have \( E[\tilde{Y}(S)] = E[\lim_{n \to \infty} \downarrow \tilde{Y}^{\nu_n}_S] = \lim_{n \to \infty} \downarrow E[\tilde{Y}^{\nu_n}_S], \) where we have used dominated convergence to exchange limit and expectation. For all \( n \), we have \( E[\tilde{Y}^{\nu_n}_S] \geq \inf_{\nu \in \mathcal{V}} E[\tilde{Y}^\nu_S]. \) We conclude that \( E[\tilde{Y}(S)] \geq \inf_{\nu \in \mathcal{V}} E[\tilde{Y}^\nu_S]. \) The proposition is thus proved. \( \square \)

We now prove Proposition 6.4.

Proof. To prove the result, we first show that the family \( (\tilde{Y}(S)) \) is right-uppersemicontinuous along stopping times in expectation. Let \( S \in \mathcal{T}_0 \), let \( (S_n) \) be a non-increasing sequence of stopping times in \( \mathcal{T}_S \) with \( \lim \downarrow S_n = S \) a.s. By the previous Lemma 6.5, we have \( E[\tilde{Y}(S_n)] = \inf_{\nu \in \mathcal{V}} E[\tilde{Y}^\nu_{S_n}], \) for all \( n \in \mathbb{N} \). Hence, \( \limsup_{n \to \infty} E[\tilde{Y}(S_n)] = \limsup_{n \to \infty} \inf_{\nu \in \mathcal{V}} E[\tilde{Y}^\nu_{S_n}] \leq \inf_{\nu \in \mathcal{V}} \limsup_{n \to \infty} E[\tilde{Y}^\nu_{S_n}], \) where we have used Fatou’s lemma to obtain the last inequality. Now, for all \( \nu \in \mathcal{V} \), the process \( (\tilde{Y}^\nu_t) \) is right-uppersemicontinuous along stopping times, so \( \limsup_{n \to \infty} \tilde{Y}^\nu_{S_n} \leq \tilde{Y}^\nu_S. \) Using this and the above computations, we get \( E[\limsup_{n \to \infty} E[\tilde{Y}(S_n)] \leq \inf_{\nu \in \mathcal{V}} E[\limsup_{n \to \infty} \tilde{Y}^\nu_{S_n}] \leq \inf_{\nu \in \mathcal{V}} E[\tilde{Y}^\nu_S] = E[\tilde{Y}(S)], \) where the (last) equality is due to Lemma 6.5. We conclude that the family \( (\tilde{Y}(S)) \) is right-uppersemicontinuous along stopping times in expectation. Hence, the family \( (\tilde{Y}(S)) \) is right-uppersemicontinuous along stopping times (cf. Theorem 12 in [9]). By Corollary 11 in [9], there exists a unique r.u.s.c. optional process \( \tilde{Y}_t \) which aggregates the family. The process \( \tilde{Y}_t \) is in \( S^2 \), due to the fact that \( E[\text{ess sup}_{S \in T} \tilde{Y}(S)^2] < +\infty. \) \( \square \)

**Remark 6.6.** Due to the above aggregation result (Proposition 6.4), we can replace \( \tilde{Y}(S) \) by \( \tilde{Y}_S \) in the representation (6.2) and in Proposition 6.3.

### 6.2 Proof of the dual representation for the buyer’s superhedging price

We now define the backward semigroup of operators \( Y^g_\xi = (Y^g_\xi_{t,T})_{0 \leq t \leq T \leq T} \) associated with a reflected BSDE with driver \( g \) and obstacle \( \xi \) (see e.g. [5] and [13]). Recall that this notion
of stochastic backward semigroup was first introduced by Peng [32] and applied to study the dynamic programming principle for stochastic control problems.

Let \( g \) be a \( \lambda \)-admissible driver. Let \( (\xi_t) \in \mathbb{S}^2 \). For each \( T' \in [0, T] \) and each \( \eta \in L^2(\mathcal{F}_{T'}) \), we define

\[
Y_{t,T'}^{g,\xi}(\eta) := Y_t, \quad 0 \leq t \leq T',
\]

(6.4)

where \( (Y_t)_{0 \leq t \leq T'} \) corresponds to the first component of the solution of the reflected BSDE associated with terminal time \( T' \), driver \( g \) and (lower) obstacle \((\xi_t)_{1 \leq t < T'} + \eta 1_{t=T'}\). Note that \( (Y_t) \) can be extended to the whole interval \([0, T]\) by setting \( Y_t = \eta \) for all \( t \in [T', T] \). \(^9\)

More generally, for each stopping time \( \theta \in \mathcal{T} \) and each \( \eta \in L^2(\mathcal{F}_\theta) \), we define \( Y_{\theta,\theta}^{g,\xi}(\eta) := Y_\theta \), where \( Y_\theta \) is the first component of the solution of the reflected BSDE associated with terminal time \( \theta \), terminal condition \( \eta \), driver \( g 1_{t \leq \theta} \), and obstacle \((\xi_t)_{1 \leq t \leq \theta} \).

For each \( \nu \in \mathcal{V} \), we consider the backward semigroup of operators \( Y_{\nu,\xi}^{f} = (Y_{t,T'}^{\nu,\xi}) \). To abbreviate the notation, we denote it by \( Y^{\nu,\xi} = (Y_{t,T'}^{\nu,\xi}) \).

Note that \( \bar{Y}_t^{\nu} = Y_{t,t,T'}^{\nu,\xi}(\xi_t) \), for all \( t \in [0, T] \), a.s.

**Proposition 6.7.** (Dynamic Programming Principle) The value process \((\bar{Y}_t)\) satisfies the following Dynamic Programming Principle: for all \( S, S' \) in \( \mathcal{T}_0 \) such that \( S \leq S' \) a.s., we have

\[
\bar{Y}_S = \text{ess inf}_{\nu \in \mathcal{V}_S} Y_{S,S'}^{\nu,\xi}(\bar{Y}_{S'}) \quad \text{a.s.} \quad (6.5)
\]

**Proof.** Let \( S, S' \in \mathcal{T} \) be such that \( S \leq S' \) a.s. By Proposition 6.3, there exists a sequence of controls \((\nu^n)_{n \in \mathbb{N}}\) with \( \nu_n \in \mathcal{V}_{S'} \) for all \( n \), such that \( \bar{Y}_{S'} = \lim_{n \rightarrow \infty} \downarrow \bar{Y}_{S'}^{\nu_n} \) a.s. Let \( \nu \in \mathcal{V}_S \).

By the continuity property of Reflected BSDEs with respect to the terminal condition (cf. last assertion of Lemma 7.1), we have \( Y_{S,S'}^{\nu,\xi}(\bar{Y}_{S'}) = Y_{S,S'}^{\nu,\xi}(\lim_{n \rightarrow \infty} \downarrow \bar{Y}_{S'}^{\nu_n}) = \lim_{n \rightarrow \infty} Y_{S,S'}^{\nu,\xi}(\bar{Y}_{S'}^{\nu_n}) \) a.s. For each \( n \), we set \( \bar{v}_n^\nu := \nu_t 1_{[S,S']}(t) + \nu_n 1_{[S',T]}(t) \). We have \( \bar{f}^{\nu_n} = \bar{f}^{\nu} 1_{[S,S']} + \bar{f}^{\nu_n} 1_{[S',T]} \) and \( \bar{Y}_{S'}^{\nu_n} = \bar{Y}_{S'}^{\nu} \). We deduce

\[
Y_{S,S'}^{\nu,\xi}(\bar{Y}_{S'}) = Y_{S,S'}^{\nu,\xi}(\bar{Y}_{S'}) = \bar{Y}_{S}^{\nu_n} \quad \text{a.s.,}
\]

where the last equality follows the flow (or semi-group) property of reflected BSDEs. We thus get

\[
Y_{S,S'}^{\nu,\xi}(\bar{Y}_{S'}) = \lim_{n \rightarrow \infty} Y_{S,S'}^{\nu,\xi}(\bar{Y}_{S'}) = \lim_{n \rightarrow \infty} \bar{Y}_{S}^{\nu_n} \geq \bar{Y}_S \quad \text{a.s.,}
\]

where the (last) inequality follows from (6.2). As \( \nu \in \mathcal{V}_S \) is arbitrary, we derive \( \text{ess inf}_{\nu \in \mathcal{V}_S} Y_{S,S'}^{\nu,\xi}(\bar{Y}_{S'}) \geq \bar{Y}_S \) a.s.

We now prove the converse inequality. Let \( \nu \in \mathcal{V}_S \). By the flow property of reflected BSDEs, we have \( \bar{Y}_S^{\nu} = Y_{S,S'}^{\nu,\xi}(\bar{Y}_{S'}) \) a.s. On the other hand, \( \bar{Y}_S^{\nu} \geq \bar{Y}_S^{\nu} \) a.s. (cf. property (6.2)). From this, by the comparison theorem for reflected BSDEs (cf. ), we deduce \( Y_{S,S'}^{\nu,\xi}(\bar{Y}_{S'}) \geq Y_{S,S'}^{\nu,\xi}(\bar{Y}_{S'}) \) a.s. Hence, \( \bar{Y}_S^{\nu} = Y_{S,S'}^{\nu,\xi}(\bar{Y}_{S'}) \geq Y_{S,S'}^{\nu,\xi}(\bar{Y}_{S'}) \) a.s. By taking the essential infimum

\(^9\)Recall that, by the flow property for reflected BSDEs, the family of operators \( Y_{g,\xi}^{g,\xi} = \left( Y_{t,T'}^{g,\xi}\right)_{0 \leq t \leq T' \leq T} \) satisfies a semi-group property.
over $\nu \in \mathcal{V}_S$, we get $\text{ess inf}_{\nu \in \mathcal{V}_S} Y^\nu_t \geq \text{ess inf}_{\nu \in \mathcal{V}_S} Y^\nu_{S,S'}(\tilde{Y}_{S'})$ a.s. But, $\tilde{Y}_{S} = \text{ess inf}_{\nu \in \mathcal{V}_S} Y^\nu_t$ a.s. (cf. (6.2)). Hence, $\tilde{Y}_{S} \geq \text{ess inf}_{\nu \in \mathcal{V}_S} Y^\nu_{S,S'}(\tilde{Y}_{S'})$ a.s., which is the desired inequality. As both inequalities hold, we have the equality (6.5). The proof is complete. ∎

We recall that, by Proposition 6.4, the value process $(\tilde{Y}_t)$ is right upper-semicontinuous (without any regularity assumption on the process $(\xi_t)$).

Let $(\tilde{\xi}_t)$ be the right-u.s.c. process defined by

$$\tilde{\xi}_t := \limsup_{s \downarrow t, s \geq t} \xi_s, \quad \text{for all } t \in [0, T].$$

(6.6)

We now show that if the process $(\tilde{\xi}_t)$ is right-lowersemicontinuous (right-l.s.c.), then $(\tilde{Y}_t)$ is also right-l.s.c., hence right-continuous.

**Proposition 6.8** (The case when $(\tilde{\xi}_t)$ is right-lowersemicontinuous). Let $(\tilde{\xi}_t) \in \mathbb{S}^2$. Suppose that $(\tilde{\xi}_t)$ is right-l.s.c. (which is satisfied if, for example, the process $\xi$ is right-limited and right-l.s.c.). Then, the value process $(\tilde{Y}_t)$ of the problem of control and stopping (6.1) is right-l.s.c.

**Proof.** Let $S \in \mathcal{T}_0$, let $(S_n)$ be a non-increasing sequence of stopping times in $\mathcal{T}_S$ with $\lim_{n \to +\infty} S_n = S$ a.s. and for all $n \in \mathbb{N}$, $S_n > S$ a.s. on $\{S < T\}$, and such that $\lim_{n \to +\infty} \tilde{Y}_{S_n}$ exists a.s. Since $0 \in \mathcal{V}_S$, by the dynamic programming principle, we have $\tilde{Y}_S \leq Y^{0,\xi}_{S,S_n}(\tilde{Y}_{S_n})$ a.s. Hence, by the continuity property of Reflected BSDEs with respect to the pair terminal time-terminal condition 12 (cf. Lemma 7.1), we thus get

$$\tilde{Y}_S \leq \lim_{n \to \infty} Y^{0,\xi}_{S,S_n}(\tilde{Y}_{S_n}) = Y^{0,\xi}_{S,S}(\lim_{n \to \infty} \tilde{Y}_{S_n}) = \lim_{n \to +\infty} \tilde{Y}_{S_n} \quad \text{a.s.}$$

By Proposition 2 of Dellacherie and Lenglart [9], the process $\tilde{Y}$ is thus right-lowersemicontinuous. The proof is thus complete. ∎

**Remark 6.9.** The above proof also shows the following property: Let $S \in \mathcal{T}$. If $(\tilde{\xi}_t)$ is right-l.s.c. at $S$ (which is satisfied if, for example, the process $\xi$ is right-limited and right-l.s.c. at $S$), then, the value process $(\tilde{Y}_t)$ is right-l.s.c. at $S$.

---

10Note that $\hat{\xi}_t = \max(\xi_t, \xi_t)$, where $\xi_t$ denotes the right upper-semicontinuous envelope of the process $(\tilde{\xi}_t)$, defined by $\xi_t := \limsup_{s \downarrow t, s \geq t} \xi_s$, for all $t \in [0, T]$ in [15, page 133]. Note also that $(\hat{\xi}_t)$ is a right-u.s.c. progressive process.

11Indeed, in this case, we have $\xi_t = \max(\xi_t, \xi_t)$. Moreover, the right-l.s.c. property of $\xi$ is equivalent to the condition $\xi_{t+} \geq \xi_t$, which is equivalent to $\xi_t = \xi_{t+}$.

12We note that the conditions from Lemma 7.1 are satisfied here, that is, the condition (7.1), which is written here as the condition $\lim_{n \to +\infty} \tilde{Y}_{S_n} \geq \xi_S$, holds: indeed, since $\tilde{Y}$ is right-u.s.c., we have $\tilde{Y}_{S_n} \geq \xi_{S_n}$ a.s. for all $n$; hence, $\lim_{n \to +\infty} \tilde{Y}_{S_n} \geq \text{ess inf}_{n \to +\infty} \xi_{S_n} \geq \xi_S$ a.s., where we have used the assumption of right-lowersemicontinuity of $\xi$ for the last inequality.
Lemma 6.10. Let \((\xi_t)\) be a process in \(\mathbb{S}^2\). We define the following stopping times:

\[
\bar{\tau} := \inf\{t \in [0,T] : \bar{Y}_t = \xi_t\}
\]

For \(\varepsilon > 0\), \(\bar{\tau}_\varepsilon := \inf\{t \in [0,T] : \bar{Y}_t \leq \xi_t + \varepsilon\}\)

We note that \(\bar{\tau}^\varepsilon \leq \bar{\tau}\) a.s.

(i) If \((\xi_t)\) is left-uppersemicontinuous along stopping times at \(\bar{\tau}\), then, for all \(\nu \in \mathcal{V}\), the value process \((\bar{Y}_t)\) is a strong \(\bar{\mathcal{E}}^\nu\)-submartingale on \([0,\bar{\tau}]\).

(ii) For all \(\varepsilon > 0\), for all \(\nu \in \mathcal{V}\), the value process \((\bar{Y}_t)\) is a strong \(\bar{\mathcal{E}}^\nu\)-submartingale on \([0,\bar{\tau}_\varepsilon]\).

Proof. We show (i). Let \(\nu \in \mathcal{V}\). Let \(S, \tau\) in \(\mathcal{T}\) be such that \(0 \leq S \leq \tau \leq \bar{\tau}\) a.s. We show that \(\bar{\mathcal{E}}^\nu_{S,\tau}(\bar{Y}_\tau) \geq \bar{Y}_S\). By the representation (6.2) and Proposition 6.3, there exists a minimizing sequence for \(\bar{Y}_\tau\), that is, there exists \(\nu^p := \nu^p(\tau) \in \mathcal{V}_\tau\) such that \(\bar{Y}_\tau = \lim_{p \to \infty} \downarrow \bar{Y}_{\tau}^{\nu^p}\).

Hence, \(\bar{\mathcal{E}}^\nu_{S,\tau}(\bar{Y}_\tau) = \bar{\mathcal{E}}^\nu_{S,\tau}(\lim_{p \to \infty} \bar{Y}_{\tau}^{\nu^p}) = \lim_{p \to \infty} \bar{\mathcal{E}}^\nu_{S,\tau}(\bar{Y}_{\tau}^{\nu^p})\), where we have used the continuity property of the non-linear expectation \(\mathcal{E}^\nu(\cdot)\) with respect to terminal condition. For all \(p \in \mathbb{N}\), we set \(\bar{\nu}^p := \nu^p[I\{t > \tau\}] + \nu[I\{t \leq \tau\}]\). We have \(\bar{\nu}^p \in \mathcal{V}\). We thus get \(\lim_{p \to \infty} \bar{\mathcal{E}}^\nu_{S,\tau}(\bar{Y}_{\tau}^{\nu^p}) = \lim_{p \to \infty} \bar{\mathcal{E}}^\nu_{S,\tau}(\bar{Y}_{\tau}^{\nu^p}) \geq \text{ess inf}_{\mu \in \mathcal{V}} \bar{\mathcal{E}}^\mu_{S,\tau}(\bar{Y}_\tau^{\nu^p})\). Putting together the above computations gives

\[
\bar{\mathcal{E}}^\nu_{S,\tau}(\bar{Y}_\tau) \geq \text{ess inf}_{\mu \in \mathcal{V}} \bar{\mathcal{E}}^\mu_{S,\tau}(\bar{Y}_\tau^{\nu^p}).
\]

For all \(\mu \in \mathcal{V}\), we set \(\tau^\mu := \inf\{t \in [0,T] : \bar{Y}_t^{\mu} = \xi_t\}\). We notice that, for all \(\mu \in \mathcal{V}\), \(\bar{\tau} \leq \tau^\mu\) a.s.; this follows from the definitions of \(\bar{\tau}\) and \(\tau^\mu\) and from the fact that \(\xi_t \leq \bar{Y}_t \leq \bar{Y}_t^{\mu}\) for all \(t\) a.s. By Lemma 4.1 in [21], for all \(\mu \in \mathcal{V}\), the process \((\bar{Y}_t^{\mu})\) is a strong \(\bar{\mathcal{E}}^\mu\)-martingale on \([0,\tau^\mu]\); hence, also a strong \(\bar{\mathcal{E}}^\mu\)-martingale on \([0,\bar{\tau}]\) (as \(\bar{\tau} \leq \tau^\mu\) a.s.). Hence, for all \(\mu \in \mathcal{V}\), \(\bar{\mathcal{E}}^\mu_{S,\tau}(\bar{Y}_\tau^{\mu}) = \bar{Y}_S^{\mu}\) (recall that \(0 \leq S \leq \tau \leq \bar{\tau}\) a.s.) Using this and (6.9), we get \(\bar{\mathcal{E}}^\nu_{S,\tau}(\bar{Y}_\tau) \geq \text{ess inf}_{\mu \in \mathcal{V}} \bar{Y}_S^{\mu} = \bar{Y}_S\), where the (last) equality is due to the representation (6.2). Property (i) is thus proved.

Let us show (ii). Let \(\varepsilon > 0\). Let \(S, \tau\) in \(\mathcal{T}\) be such that \(0 \leq S \leq \tau \leq \bar{\tau}_\varepsilon\) a.s. By exactly the same arguments as in part (i), we get

\[
\bar{\mathcal{E}}^\nu_{S,\tau}(\bar{Y}_\tau) \geq \text{ess inf}_{\mu \in \mathcal{V}} \bar{\mathcal{E}}^\mu_{S,\tau}(\bar{Y}_\tau^{\nu^p}).
\]

For all \(\mu \in \mathcal{V}\), we set \(\bar{\tau}^\mu := \inf\{t \in [0,T] : \bar{Y}_t^{\mu} \leq \xi_t + \varepsilon\}\). We note that, for all \(\mu \in \mathcal{V}\), \(\bar{\tau} \leq \tau^\mu\) a.s. By Lemma 4.1 in [21], for all \(\mu \in \mathcal{V}\), the process \((\bar{Y}_t^{\mu})\) is a strong \(\bar{\mathcal{E}}^\mu\)-martingale on \([0,\tau^\mu]\); hence, also a strong \(\bar{\mathcal{E}}^\mu\)-martingale on \([0,\bar{\tau}_\varepsilon]\) (as \(\bar{\tau} \leq \tau^\mu\) a.s.). From this and (6.10), we conclude as in part (i). \(\square\)

We will now give a dual representation for the buyer’s superhedging price \(\tilde{u}_0\) in terms of the value (at time 0) of the non-linear problem of control and stopping studied above. We also give a superhedger for the buyer. From this result, we will deduce the dual representation (in terms of the \(f\)-martingale probability measures) stated in Theorem 6.1.
Theorem 6.11 (Buyer’s superhedging price). Let \((\xi_t) \in \mathbb{S}^2\).
Suppose that \((\xi_t)\) is right-continuous and left-u.s.c. along stopping times.
The buyer’s price \(\tilde{u}_0\) of the American option satisfies
\[
\tilde{u}_0 = \inf_{\nu \in \mathcal{V}} \sup_{\tau \in \mathcal{T}} \tilde{E}_0^{\nu}(\xi_\tau).
\]

(6.11)

Let \(\tilde{\tau} := \inf\{t \in [0,T] : \tilde{Y}_t = \xi_t\}\). There exists a portfolio strategy \(\tilde{\varphi} \in H^2\) such that \((\tilde{\tau}, \tilde{\varphi})\) is a superhedging strategy for the buyer, that is, such that \((\tilde{\tau}, \tilde{\varphi}) \in \mathcal{B}(\tilde{u}_0)\).

Remark 6.12. This result still holds under the following (weaker) local assumptions:
(i) the processes \(\tilde{Y}\) and \(\xi\) are respectively right-l.s.c. and right-u.s.c. at \(\tilde{\tau}\) (which, by Proposition 6.9, is satisfied if, for example, \(\xi\) is right-continuous at \(\tilde{\tau}\)).
(ii) \(\xi\) is left-u.s.c. along stopping times at \(\tilde{\tau}\).

Proof. It is sufficient to show that \(\tilde{u}_0 = \tilde{Y}_0\) and that there exists \((\tilde{\tau}, \tilde{\varphi}) \in \mathcal{B}(\tilde{Y}_0)\).
Let \(\mathcal{S}\) be the set of initial prices which allow the buyer to be “superhedged”, that is \(\mathcal{S} = \{x \in \mathbb{R} : \exists \sigma, \varphi \in \mathcal{B}(x)\}\). Note that \(\tilde{u}_0 = \sup \mathcal{S}\).

Let us first show that \(\tilde{u}_0 \leq \tilde{Y}_0\). Let \(x \in \mathcal{S}\). By definition of \(\mathcal{S}\), there exists \((\theta, \varphi) \in \mathcal{B}(x)\), that is, such that \(V_0^{-x,\varphi} \geq -\xi_0\) a.s. Let \(\nu \in \mathcal{V}\). By taking the \(\mathcal{E}^\nu\)-evaluation in the above inequality, using the monotonicity of \(\mathcal{E}^\nu\) and the \(\mathcal{E}^\nu\)-martingale property of the process \(V^{-x,\varphi}\), we derive that \(-x = \mathcal{E}^\nu_0(\xi_0) \geq \mathcal{E}^\nu_0(-\xi_0) = -\mathcal{E}^\nu_0(\xi_0)\), where the last equality follows from the first assertion of Remark 6.2. We deduce \(x \leq \sup_{\tau \in \mathcal{T}} \tilde{\mathcal{E}}^{\nu}_{0,\tau}(\xi_\tau)\). Since \(\nu \in \mathcal{V}\) is arbitrary, we get
\[
\tilde{Y}_0 \leq \inf_{\nu \in \mathcal{V}} \sup_{\tau \in \mathcal{T}} \tilde{\mathcal{E}}^{\nu}_{0,\tau}(\xi_\tau) = \tilde{Y}_0,
\]
which holds for any \(x \in \mathcal{S}\). By taking the supremum over \(x \in \mathcal{S}\), we get \(\tilde{u}_0 \leq \tilde{Y}_0\).

Let us now show that \(\tilde{Y}_0 \leq \tilde{u}_0\). To this aim, we prove that \(\tilde{Y}_0 \in \mathcal{S}\), that is, there exists a portfolio strategy \(\tilde{\varphi} \in H^2\) such that
\[
(\tilde{\tau}, \tilde{\varphi}) \in \mathcal{B}(\tilde{Y}_0).
\]

(6.12)

Since \(\xi\) is left-u.s.c. along stopping times at \(\tilde{\tau}\), by the first assertion from Lemma 6.10, the process \((\tilde{Y}_t, \tilde{\tau})\) is a strong \(\mathcal{E}\)-submartingale for all \(\nu \in \mathcal{V}\). This together with the first assertion from Remark 6.2 implies that \((-\tilde{Y}_{t \wedge \tilde{\tau}})\) is a strong \(\mathcal{E}\)-supermartingale for all \(\nu \in \mathcal{V}\).

By the optional \(\mathcal{E}^{\delta}\)-decomposition of strong \(\mathcal{E}\)-supermartingale for each \(\nu \in \mathcal{V}\) (cf. Theorem B.4 in [23]), there exists a unique pair \((\tilde{Z}, \tilde{C}) \in H^2 \times \mathbb{C}^2\) and a unique nondecreasing optional RCLL process \(\tilde{h}\), with \(\tilde{h}_0 = 0\) and \(E[\tilde{h}_T^2] < \infty\) such that
\[
-\tilde{Y}_t = -\tilde{Y}_0 - \int_0^t f(s, -\tilde{Y}_s, \tilde{Z}_s)ds + \int_0^t \tilde{Z}_s\sigma_s^{-1}(\sigma_s dW_s + \beta_s dM_s) - \tilde{h}_t - \tilde{C}_t, \quad 0 \leq t \leq \tilde{\tau} \text{ a.s.}
\]

(6.13)

\[\text{\textsuperscript{13}}\]Indeed, these assumptions are sufficient to ensure the inequality (6.16).
\[\text{\textsuperscript{14}}\]Indeed, this assumption is sufficient to apply the first assertion from Lemma 6.10, which is used in the proof.
We now consider the portfolio associated with the initial capital $-\tilde{Y}_0$ and the strategy
\[ \tilde{\phi} := \sigma^{-1} \tilde{Z}. \] (6.14)

By (3.2)-(3.3), the value of the portfolio process $(V_{t}^{\tilde{Y}_0, \tilde{\phi}})$ satisfies:
\[ V_{t}^{\tilde{Y}_0, \tilde{\phi}} = -\tilde{Y}_0 - \int_0^t f(s, V_s^{\tilde{Y}_0, \tilde{\phi}}, \tilde{Z}_s) ds + \int_0^t \tilde{Z}_s \sigma_s^{-1}(\sigma_s dW_s + \beta_s dM_s), \quad 0 \leq t \leq T. \] (6.15)

By (6.13) and (6.15) and the comparison result for forward differential equations, we get $-\tilde{Y}_t \leq V_{t}^{\tilde{Y}_0, \tilde{\phi}}, 0 \leq t \leq \tilde{\tau}$ a.s. We thus have $V_{\tilde{\tau}}^{\tilde{Y}_0, \tilde{\phi}} + \tilde{Y}_{\tilde{\tau}} \geq 0$ a.s.

Now, since $\xi$ is right-continuous, by Proposition 6.8, $\tilde{Y}$ is right-l.s.c. (and even right-continuous). Hence, by the definition of $\tilde{\tau}$ (and since $\xi$ is right-u.s.c.), we get
\[ \tilde{Y}_{\tilde{\tau}} \leq \xi_{\tilde{\tau}} \quad \text{a.s.} \] (6.16)

We thus conclude that
\[ V_{\tilde{\tau}}^{\tilde{Y}_0, \tilde{\phi}} + \xi_{\tilde{\tau}} \geq 0 \quad \text{a.s.,} \]
which implies the desired property (6.12). We thus have $\tilde{Y}_0 \leq \tilde{u}_0$. It follows that $\tilde{u}_0 = \tilde{Y}_0$. By (6.12), we get $(\tilde{\tau}, \tilde{\phi}) \in \mathcal{B}(\tilde{u}_0)$, which completes the proof. \hfill \Box

\begin{remark}
We emphasize that the superhedging portfolio strategy $\tilde{\phi}$ is given by (6.14) via the optional decomposition (6.13) of $\tilde{Y}$ on $[0, \tilde{\tau}]$.
\end{remark}

\begin{proof}[Proof of Theorem 6.1]
The proof follows from the previous Theorem 6.11 and from Remark 6.2. We note first that, since $(\xi_t)$ is supposed to be right-continuous and left-uppersemicontinuous along stopping times, it follows that $\xi = \xi$, and the assumptions of Theorem 6.11 hold.

Under the additional integrability condition $\psi \in \bigcap_{\nu \in \mathcal{V}} \mathbb{H}^2_{Q^\nu}$ on the process $\psi$ from Assumption (4.1), by Remark 6.2, the dual representation (6.11) can be written in terms of the $f$-martingale probability measures, that is
\[ \tilde{u}_0 = \inf_{\nu \in \mathcal{V}} \sup_{\tau \in \mathcal{T}} \{-\mathcal{E}_t^f_{Q^\nu,0,\tau}(-\xi_\tau)\}. \]

The fact that the infimum and the supremum can be interchanged follows from Proposition 6.19 (shown under weaker regularity assumptions on $\xi$). The proof of Theorem 6.1 is thus complete. \hfill \Box

\subsection{Buyer’s nearly superhedging price}
We now consider the case when $\xi$ does not satisfy any regularity assumption on the left. We introduce the definition of an $\varepsilon$-superhedge for the buyer:

\section{6.3 Buyer’s nearly superhedging price}

We now consider the case when $\xi$ does not satisfy any regularity assumption on the left. We introduce the definition of an $\varepsilon$-superhedge for the buyer:
Definition 6.14. For each initial price \( z \) and for each \( \varepsilon > 0 \), an \( \varepsilon \)-superhedge for the buyer against the American option is a pair \((\tau, \varphi)\) of a stopping time \( \tau \in \mathcal{T} \) and a portfolio strategy \( \varphi \in \mathbb{H}^2 \) such that

\[
V_{\tau}^{-z, \varphi} \geq -\xi_{\tau} - \varepsilon \quad \text{a.s.}
\]

For each \( z \in \mathbb{R} \) and each \( \varepsilon > 0 \), we denote by \( \mathcal{B}_z(\varepsilon) \) the set of all \( \varepsilon \)-superhedges for the buyer associated with initial price \( z \).

We introduce the nearly superhedging price \( \bar{u}_0 \) of the American option for the buyer as the supremum of the initial prices which allow the buyer to be \( \varepsilon \)-superhedged for all \( \varepsilon > 0 \), that is,

\[
\bar{u}_0 = \sup\{ z \in \mathbb{R} , \ \forall \varepsilon > 0, \exists (\tau, \varphi) \in \mathcal{B}_z(\varepsilon) \}.
\] (6.17)

Theorem 6.15 (Buyer’s nearly superhedging price). Let \( (\xi_t) \in \mathcal{S}^2 \) supposed to be right-continuous. The buyer’s nearly superhedging price \( \bar{u}_0 \) of the American option satisfies

\[
\bar{u}_0 = \inf_{\nu \in \mathcal{V}} \sup_{\tau \in \mathcal{T}} \bar{E}_0,\tau(\xi_\tau).
\] (6.18)

For each \( \varepsilon > 0 \), let \( \bar{\tau}_\varepsilon := \inf\{ t \in [0, T] : \bar{Y}_t \leq \xi_t + \varepsilon \} \). There exists a portfolio strategy \( \bar{\varphi} \in \mathbb{H}^2 \) such that, for each \( \varepsilon > 0 \), the pair \((\bar{\tau}_\varepsilon, \bar{\varphi})\) is an \( \varepsilon \)-superhedge for the buyer (associated with the initial price \( \bar{u}_0 \)).

Remark 6.16. We note that when \( \xi \) is left-u.s.c. along stopping times at \( \bar{\tau} \), the buyer’s nearly superhedging price is equal to the buyer’s superhedging price.

Remark 6.17. The result from Theorem 6.15 still holds under the following (weaker) local assumptions: the processes \( \bar{Y} \) and \( \bar{\xi} \) are respectively right-l.s.c. and right-u.s.c. at \( \bar{\tau}_{\varepsilon_n} \), for a sequence \((\varepsilon_n)\) tending to \( 0 \) (which, by Proposition 6.9, is satisfied if, for example, \( \bar{\xi} \) is right-continuous at \( \bar{\tau}_{\varepsilon_n} \) for all \( n \)).

Proof. Let us first show that \( \bar{u}_0 \leq \bar{Y}_0 \).

Let \( z \in \mathbb{R} \) be such that, for each \( \varepsilon > 0 \), there exists \((\tau_\varepsilon, \varphi_\varepsilon) \in \mathcal{B}_z(\varepsilon) \).

Fix now \( \varepsilon > 0 \). By definition of \( \mathcal{B}_z(\varepsilon) \), there exists \((\tau_\varepsilon, \varphi_\varepsilon) \in \mathcal{T} \times \mathbb{H}^2 \) such that

\[
V_{\tau_\varepsilon}^{-z, \varphi_\varepsilon} \geq -\xi_{\tau_\varepsilon} - \varepsilon \quad \text{a.s.}
\]

Let \( \nu \in \mathcal{V} \). By taking the \( \mathcal{E}_\nu \)-evaluation in the above inequality, using the monotonicity of \( \mathcal{E}_\nu \) and the \( \mathcal{E}_\nu \)-martingale property of the process \( V_{\tau_\varepsilon}^{-z, \varphi_\varepsilon} \), we derive that

\[
-z = \mathcal{E}_{0, \tau_\varepsilon}^\nu (V_{\tau_\varepsilon}^{-z, \varphi_\varepsilon}) \geq \mathcal{E}_{0, \tau_\varepsilon}^\nu (-\xi_{\tau_\varepsilon} - \varepsilon).
\] (6.19)

Now, by Lemma 7.3, we get

\[
\mathcal{E}_{0, \tau_\varepsilon}^\nu (-\xi_{\tau_\varepsilon}) - \mathcal{E}_{0, \tau_\varepsilon}^\nu (-\xi_{\tau_\varepsilon} - \varepsilon) = E[e^{\int_{\tau_\varepsilon}^{\bar{\tau}_\varepsilon} f_y(s) ds} H_{0, \tau_\varepsilon} \varepsilon] \leq e^{C T \varepsilon} E[H_{0, \tau_\varepsilon}] = e^{C T \varepsilon} \quad \text{a.s.},
\]

where the inequality and the last equality follow from the fact that the process \( f_y(\cdot) \) is uniformly bounded by the Lipschitz constant \( C \) of \( f \), and the fact that, since \( \nu \in \mathcal{V} \), the process \( H_{0, \cdot} \) is a nonnegative martingale. We thus have

\[
-\mathcal{E}_{0, \tau_\varepsilon}^\nu (-\xi_{\tau_\varepsilon} - \varepsilon) \leq e^{C T \varepsilon} - \mathcal{E}_{0, \tau_\varepsilon}^\nu (-\xi_{\tau_\varepsilon}) = e^{C T \varepsilon} + \bar{E}_{0, \tau_\varepsilon}^\nu (\xi_{\tau_\varepsilon}),
\] (6.20)

\[15\] Indeed, these assumptions are sufficient to ensure the inequality (6.21) at \( \bar{\tau}_{\varepsilon_n} \) for all \( n \).
where the last equality follows from Remark 6.2.
Using (6.19), we deduce $z \leq e^{CT} \varepsilon + \tilde{E}_{0,\tau}^{\nu}(\xi_{\tau}) \leq e^{CT} \varepsilon + \sup_{\tau \in T} \tilde{E}_{0,\tau}^{\nu}(\xi_{\tau})$. Since this inequality holds for all $\varepsilon > 0$, we get $z \leq \sup_{\tau \in T} \tilde{E}_{0,\tau}^{\nu}(\xi_{\tau})$. As $\nu \in \mathcal{V}$ is arbitrary, we deduce

$$z \leq \inf_{\nu \in \mathcal{V}} \sup_{\tau \in T} \tilde{E}_{0,\tau}^{\nu}(\xi_{\tau}) = \bar{Y}_0.$$  

Using the definition of $\bar{u}_0$ as a supremum (cf. (6.17)), we get $\bar{u}_0 \leq \bar{Y}_0$.

We now show that $\bar{Y}_0 \leq \bar{u}_0$. Let $\varepsilon > 0$. By the second assertion of Lemma 6.10, the process $(\bar{Y}_{t \wedge \tilde{\tau}_\varepsilon})$ is a strong $\tilde{\mathcal{E}}^\nu$-submartingale for all $\nu \in \mathcal{V}$. This together with the first assertion from Remark 6.2 implies that $(-\bar{Y}_{t \wedge \tilde{\tau}_\varepsilon})$ is a strong $\tilde{\mathcal{E}}^\nu$-supermartingale for all $\nu \in \mathcal{V}$. By the optional $\mathcal{F}^t$-decomposition of strong $\tilde{\mathcal{E}}^\nu$-supermartingale for each $\nu \in \mathcal{V}$ (see Theorem B.4 in [23] applied to the right-continuous process $-\bar{Y}$), there exists a unique process $\tilde{Z} \in \mathbb{H}^2$ and a unique nondecreasing optional RCLL process $\tilde{h}$, with $\tilde{h}_0 = 0$ and $E[\tilde{h}_T^2] < \infty$ such that (6.13) holds on $[0, \tilde{\tau}_\varepsilon]$. Moreover, the wealth $V^{-\bar{Y}_{0,\tilde{\varphi}}}$ associated with the initial capital $-\bar{Y}_0$ and the strategy $\tilde{\varphi} := \sigma^{-1}\tilde{Z}$ is the solution of the forward differential equation (6.15). By the comparison result for forward differential equations, it follows that $-\bar{Y}_t \leq V_t^{-\bar{Y}_{0,\tilde{\varphi}}}$, $0 \leq t \leq \tilde{\tau}_\varepsilon$ a.s.

Now, since $\xi$ is right-continuous, by Proposition 6.8, $\bar{Y}$ is right-l.s.c. (and even right-continuous). Hence, by the definition of $\tilde{\tau}_\varepsilon$ (and the right-uppersemicontinuity of $\xi$), we get

$$\bar{Y}_{\tilde{\tau}_\varepsilon} \leq \xi_{\tilde{\tau}_\varepsilon} + \varepsilon \quad \text{a.s.} \quad (6.21)$$

We thus obtain the inequality $V^{-\bar{Y}_{0,\tilde{\varphi}}}_{\tilde{\tau}_\varepsilon} \geq -\bar{Y}_{\tilde{\tau}_\varepsilon} \geq -\xi_{\tilde{\tau}_\varepsilon} - \varepsilon \text{ a.s.}$

Hence, for each $\varepsilon > 0$, the pair $(\tilde{\tau}_\varepsilon, \tilde{\varphi})$ is an $\varepsilon$-superhedge for the buyer associated with the initial price $\bar{Y}_0$, that is

$$(\tilde{\tau}_\varepsilon, \tilde{\varphi}) \in \mathcal{B}_\varepsilon(\bar{Y}_0). \quad (6.22)$$

Using the definition of $\bar{u}_0$, we get $\bar{Y}_0 \leq \bar{u}_0$. It follows that $\bar{u}_0 = \bar{Y}_0$. By (6.22), we derive that for each $\varepsilon > 0$, $(\tilde{\tau}_\varepsilon, \tilde{\varphi}) \in \mathcal{B}_\varepsilon(\bar{u}_0)$, which completes the proof. \[ \square \]

**Remark 6.18.** In the complete case, Theorem 6.15 still holds without the assumption that $(\xi_t)$ is right-l.s.c. Indeed, in this case, $\mathcal{Q} = \{P\}$ and $\bar{Y} = \bar{Y}^0$, where $\bar{Y}^0$ is the solution of the reflected BSDE associated with driver $\tilde{f}$, lower obstacle $\xi$ and terminal time $T$, which, by the Skorokhod condition, implies that $\bar{Y}^0_{\tilde{\tau}_\varepsilon^+} - \bar{Y}^0_{\tilde{\tau}_\varepsilon} = 0$ a.s. on the set $\{\bar{Y}^0_{\tilde{\tau}_\varepsilon} > \xi_{\tilde{\tau}_\varepsilon}\}$. This allows us to obtain the inequality (6.21) even if $\bar{Y}^0$ is not right-l.s.c. at $\tilde{\tau}_\varepsilon$ (see the proof of Lemma 4.1 in [20] for details).

We now show that the operations of infimum and supremum in the dual representation (6.11) (resp. (6.18)) of the buyer’s superhedging (resp. nearly superhedging) price can be interchanged.

28
Proposition 6.19. Let \((\xi_t) \in S^2\), supposed to be right-continuous.\(^{16}\) We have
\[
\inf_{\nu \in \mathcal{V}} \sup_{\tau \in T} \tilde{\mathcal{E}}^\nu_{0,\tau}(\xi_\tau) = \sup_{\tau \in T} \inf_{\nu \in \mathcal{V}} \tilde{\mathcal{E}}^\nu_{0,\tau}(\xi_\tau).
\]

Proof. We clearly have the inequality \(\sup_{\tau \in T} \inf_{\nu \in \mathcal{V}} \tilde{\mathcal{E}}^\nu_{0,\tau}(\xi_\tau) \leq \inf_{\nu \in \mathcal{V}} \sup_{\tau \in T} \tilde{\mathcal{E}}^\nu_{0,\tau}(\xi_\tau)\).

It remains to show the converse inequality, that is
\[
\tilde{Y}_0 \leq \sup_{\tau \in T} \inf_{\nu \in \mathcal{V}} \tilde{\mathcal{E}}^\nu_{0,\tau}(\xi_\tau).
\]
(6.23)

By Lemma 6.10 (ii), for all \(\epsilon > 0\), for all \(\nu \in \mathcal{V}\), the value process \((\tilde{Y}_\nu)\) is a strong \(\tilde{\mathcal{E}}^\nu\)-submartingale on \([0, \tilde{\tau}_\epsilon]\), where \(\tilde{\tau}_\epsilon\) is defined by (6.8). Hence, \(\tilde{Y}_0 \leq \tilde{\mathcal{E}}^\nu_{0,\tilde{\tau}_\epsilon}(\tilde{Y}_{\tilde{\tau}_\epsilon})\). Recall that \(\tilde{Y}_{\tilde{\tau}_\epsilon} \leq \xi_{\tilde{\tau}_\epsilon} + \epsilon\) a.s. (cf. (6.21)). By the same arguments as those used in the proof of Theorem 6.15 to show the estimate (6.20), we derive that for all \(\nu \in \mathcal{V}\),
\[
\tilde{Y}_0 \leq \tilde{\mathcal{E}}^\nu_{0,\tilde{\tau}_\epsilon}(\tilde{Y}_{\tilde{\tau}_\epsilon}) \leq \tilde{\mathcal{E}}^\nu_{0,\tilde{\tau}_\epsilon}(\xi_{\tilde{\tau}_\epsilon} + \epsilon) \leq e^{CT_\epsilon} \epsilon + \tilde{\mathcal{E}}^\nu_{0,\tilde{\tau}_\epsilon}(\xi_{\tilde{\tau}_\epsilon}).
\]
(6.24)

By taking the infimum over \(\nu \in \mathcal{V}\), we obtain
\[
\tilde{Y}_0 \leq e^{CT_\epsilon} \epsilon + \inf_{\nu \in \mathcal{V}} \tilde{\mathcal{E}}^\nu_{0,\tilde{\tau}_\epsilon}(\xi_{\tilde{\tau}_\epsilon}) \leq e^{CT_\epsilon} \epsilon + \sup_{\tau \in T} \inf_{\nu \in \mathcal{V}} \tilde{\mathcal{E}}^\nu_{0,\tau}(\xi_\tau).
\]

Since this inequality holds for all \(\epsilon > 0\), we get the inequality (6.23). The proof is thus complete. \(\square\)

7 Appendix

In this Appendix, we provide some useful results.

We first show that the non-linear operator \(Y^{g,\xi}\) induced by the reflected BSDE with driver \(g\) and obstacle \((\xi_t)_{t \in T}\), defined by (6.4), simply denoted by \(Y^g\), is continuous with respect to the terminal condition. Moreover, for each \(\theta \in T_0\) and each \(\eta \in L^2(\mathcal{G}_\theta)\), \(Y^g\) is continuous with respect to the pair terminal time-terminal condition at the point \((\theta, \eta)\) under an additional assumption on \((\xi_t)\) and \(\eta\) on a right neighborhood of \(\theta\).

Lemma 7.1. Let \(g\) be a \(\lambda\)-admissible driver satisfying Assumption 2.3. Let \((\xi_t) \in S^2\). Let \((\tilde{\xi}_t)\) be the right-u.s.c. process defined by \(\tilde{\xi}_t := \limsup_{s \downarrow t, s \geq t} \xi_s\), for all \(t \in [0, T]\).

Let \((\theta^n)_{n \in \mathbb{N}}\) be a non increasing sequence of stopping times in \(T_0\), converging a.s. to \(\theta\). Let \((\eta^n)_{n \in \mathbb{N}}\) be a sequence of random variables such that \(E[\sup_n (\eta^n)^2] < +\infty\), and for each \(n\), \(\eta^n\) is \(\mathcal{G}_{\theta^n}\)-measurable. Suppose that the sequence \((\eta^n)\) converges a.s. to an \(\mathcal{G}_\theta\)-measurable random variable \(\eta\). We also assume the following condition:
\[
\tilde{\xi}_\theta \leq \eta \quad \text{a.s.} \quad (7.1)
\]

Then, for each \(S \in \mathcal{T}_0\), \(\lim_{n \to +\infty} Y^g_{S,\theta^n}(\eta^n) = Y^g_{S,\theta}(\eta) \) a.s.

When for each \(n\), \(\theta_n = \theta\) a.s., the result still holds without any assumption on \((\xi_t)\).

\(^{16}\)Note that this result still holds under the assumptions from Remark 6.12 or those from Remark 6.17.
Remark 7.2. We note that the condition (7.1) is necessary in general to ensure this continuity property of the reflected operator $Y_{θ,ξ}^{g,ξ}$.

When the obstacle $(ξ_t)$ is right-u.s.c., the condition (7.1) reduces to $ξ_θ ≤ η$ a.s.

When the obstacle $(ξ_t)$ is right-continuous, we recover the continuity result shown in [13] (cf. [13, Lemma A.6]).

Proof. In the particular case when for each $n$, $θ_n = θ$ a.s., the result follows from the a priori estimates for reflected BSDEs with irregular obstacles (cf. Theorem 5.5 in [21]), which do not require any additional assumption on $(ξ_t)$.

Let us now consider the general case. Using the same arguments as those used in the proof of Lemma A.6 in [13], we show that $\liminf_{n→∞} Y_{θ,ξ_n}^{g,ξ_n}(η^n) ≥ η$ a.s.

It thus remains to show that $\limsup_{n→∞} Y_{θ,ξ_n}^{g,ξ_n}(η^n) ≤ η$ a.s. By the monotonicity property of reflected BSDEs with respect to the obstacle, for each $n ∈ \mathbb{N}$, we have $Y_{θ,ξ_n}^{g,ξ_n}(η^n) ≤ Y_{θ,ξ_n}^{g,ξ,ξ_n}(η^n)$ a.s., since $ξ ≤ ξ_n$. Let $ε > 0$. Let $n ∈ \mathbb{N}$. Recall that $Y_{θ,ξ_n}^{g,ξ_n}(η^n)$ is the solution of the reflected BSDE associated with terminal time $θ_n$ and the obstacle $(ξ_1t<θ_n + η^n1{t≥θ_n})$, which is right-u.s.c. (since $(ξ_t)$ is right-u.s.c.). Hence, by Theorem 4.2 in [20], there exists $τ_n ∈ T_θ$ such that

$$Y_{θ,ξ_n}^{g,ξ_n}(η^n) ≤ E_{θ,ξ_n,θ_n}^{g,ξ_n}(ξ_{τ_n}1{τ_n<θ_n} + η^n1{τ_n≥θ_n}) + ε \quad a.s. \quad (7.2)$$

Now, by the right-uppersemicontinuity of $ξ$ and the condition (7.1), we have $\limsup_{n→∞} Y_{τ_n,ξ_n}^{g,ξ_n}(η^n) ≤ ξ_θ ≤ η$ a.s., which implies that $\limsup_{n→∞} (ξ_{τ_n}1{τ_n<θ_n} + η^n1{τ_n≥θ_n}) ≤ η$ a.s. Hence, using the Fatou property for BSDEs with respect to the pair terminal time-terminal condition (cf. e.g. Lemma A.5 in [13]), we derive that

$$\limsup_{n→∞} E_{θ,ξ_n,θ_n}^{g,ξ_n}(ξ_{τ_n}1{τ_n<θ_n} + η^n1{τ_n≥θ_n}) ≤ E_{θ,ξ_n}^{g,ξ_n}(η) = η \quad a.s.$$ 

Hence, by (7.2), we get $\limsup_{n→∞} Y_{θ,ξ_n}^{g,ξ_n}(η^n) ≤ η + ε$ a.s. The desired result follows. \Box

We state the following result which provides, for each $ν ∈ \mathcal{V}$, a useful representation of the difference of the solutions of two BSDEs associated with the driver $f^ν$ in terms of the spread between the difference of the terminal conditions.

Lemma 7.3. Let $η_1$ and $η_2 ∈ L^2(\mathcal{G}_T)$. Let $ν ∈ \mathcal{V}$. For $i = 1, 2$, let $(X^i, Z^i, K^i)$ be the solution in $S^2 × H^2 × H^2$ of the BSDE associated with driver $f^ν$ (defined in Definition 4.3), terminal time $T$ and terminal condition $η_i$. Let $X^1_s := X^1_s − X^2_s$; $Z^1_s := Z^1_s − Z^2_s$; $K^1_s := K^1_s − K^2_s$. Let $f_y(s) := \frac{f(s, X^1_s, Z^1_s) − f(s, X^2_s, Z^1_s)}{X^1_s − X^2_s} ≠ 0$, and 0 otherwise, and let $f_z(s) := \frac{f(s, X^2_s, Z^2_s) − f(s, X^2_s, Z^1_s)}{Z^1_s − Z^2_s} ≠ 0$, and 0 otherwise. We have

$$\bar{X}_t = E[e^{{t}T}f_y(s)ds H_{t,T}(η_1 − η_2) | \mathcal{G}_t], \quad 0 ≤ t ≤ T, \quad a.s.$$ 

where $H_{t,ω}$ is solution of the following SDE

$$dH_{t,s} = H_{t,s}^− [(f_z(s) − ν_λβ_sσ_{s}−1)dW_s + ν_s dM_s]; \quad H_{t,t} = 1. \quad (7.3)$$
Proof. By a classical "linearization procedure" (as the one used at the beginning of the proof of Theorem 3 in [11]), we derive the desired result.

A result on reflected BSDEs with a non positive jump at the default time \( \vartheta \):
Let \( \mathcal{V} \) be the set of bounded predictable processes \( \nu \) such that \( \nu_t \geq 0 \) \( dP \otimes dt \)-a.e.
Let \( g \) be a \( \lambda \)-admissible driver and let \( (\delta_t) \) be a bounded predictable process.

For each \( \nu \in \mathcal{V} \), we define
\[
g^\nu(\omega, t, y, z) := g(\omega, t, y, z) + \nu_t(\omega) \lambda_t(\omega)(k - \delta_t(\omega)z)
\]
Note that \( g^\nu \) is a \( \lambda \)-admissible driver. For each \( S \in \mathcal{T} \), the value \( Y(S) \) at time \( S \) is defined by
\[
Y(S) := \text{ess sup}_{(\tau, \nu) \in T_S \times \mathcal{V}} E^{\mathcal{E}_\nu}_{S, \tau}(\xi_{\tau}),
\]
where \( \mathcal{E}^\nu = \mathcal{E}^{g^\nu} \). By the same arguments as before (cf. the proof of Corollary 4.11), there exists an r.u.s.c. process \((Y_t) \in S^2 \) which aggregates the value family \((Y(S))\), which is a strong \( \mathcal{E}^\nu \)-supermartingale for all \( \nu \in \mathcal{V} \) and \( Y_t \geq \xi_t \), for all \( t \in [0, T] \), a.s. Moreover, the process \((Y_t) \) is the smallest process in \( S^2 \) satisfying these properties.

By similar arguments as those used in the proof of Theorem 5.4, it can be shown that the value process \((Y_t) \) is a supersolution of the \emph{constrained reflected BSDE} from Definition 5.1 with \( f \) replaced by \( g \) and the constraints (5.4) replaced by the constraint (7.6) hereafter.

We thus have the following result.

**Proposition 7.4.** There exists a unique process \((Z, K, A, C) \in H^2 \times H^2_\lambda \times A^2 \times C^2 \) such that

\[
-dY_t = g(t, Y_t, Z_t, K_t)dt + dA_t + dC_t^- - Z_t dW_t - K_t dM_t; \quad Y_T = \xi_T \ a.s. \quad \text{and} \quad Y_t \geq \xi_t \ \text{for all} \ t \in [0, T] \ a.s.;
\]

\[
(Y_{\tau} - \xi_{\tau})(C_{\tau} - C_{\tau^-}) = 0 \ a.s. \ \text{for all} \ \tau \in T_0;
\]

\[
(K_t - \delta_t Z_t) \lambda_t \leq 0, \ t \in [0, T], \ dP \otimes dt - \text{a.e.} \quad (7.6)
\]

In other words, the value process \((Y_t) \) is a supersolution of the above constrained reflected BSDE. Moreover, it is the minimal one, that is, if \((Y'_t) \) is another supersolution, then \( Y'_t \geq Y_t \) for all \( t \in [0, T] \) a.s.

Note that when \( \delta = 0 \), the constraint (7.6) means that the jump of the process \((X_t) \) at the default time \( \vartheta \) is non-positive. In the case when \( \delta = 0 \) and the obstacle is right-continuous, our result gives the existence of a minimal supersolution of the reflected BSDE with driver \( g \), obstacle \( \xi \) and with non positive jumps, which corresponds to a result shown in [6] by using a penalization approach. Moreover, our result provides a dual representation (with non linear expectation) of this minimal supersolution.
