Abstract—The reproducibility of self-catalyzed molecular beam epitaxy growth of GaAs nanowires (NWs) on oxide-covered Si(111) substrates depends on the consistent quality of the oxide layer. We have developed an effective chemical treatment method to create oxide surfaces that are conducive to the nucleation of vertical GaAs NWs on Si(111). Here we demonstrate a high yield exceeding 90% of vertical GaAs NWs with density in the order of 10^9 cm^{-2} . Using a combination of chemical oxide treatment and in situ growth conditions, we investigate how to achieve a good control of the morphology and density of GaAs and GaAs/III-As core-shell NWs grown on Si.

Keywords—GaAs nanowires; molecular beam epitaxy; Ga-assisted growth; chemical treatment

III-V compound semiconductor nanowires (NWs) are a promising building block for nanoscale optoelectronic devices. Their less critical lattice-matching requirements enable flexible integration of a wide range of III-V materials in the form of NWs on cost-effective Si substrates. The growth of III-V NWs can be performed using a variety of deposition techniques via growth mechanisms similar to the vapor-liquid-solid (VLS) process, which requires a metal nanodroplet catalyst [1]. This work focuses on the self-catalyzed (also known as the Ga-assisted) growth of GaAs NWs using molecular beam epitaxy (MBE) technique, in which Ga catalytic droplets are deposited in situ to avoid defects and contamination caused by the use of extrinsic catalyst material. Recent studies have shown that a non-wetting oxide-covered surface is necessary for the formation of Ga droplets with the right contact angle to enable successful nucleation of vertical GaAs NWs on Si(111) [1,2]. There have been reports on Ga-assisted growth of NWs on Si(111) substrates covered by different types of native or fabricated oxide (SiO_2 or SiO_x) layers [2-4]. However, it remains challenging to achieve a high yield of vertical NWs and the reproducibility of the NW morphology and density tends to vary from batch to batch of Si wafers.

In this work, we investigate the effects of chemical treatment and oxidation of Si(111) substrate on the yield and reproducibility of vertical GaAs NWs. The growth of NWs is carried out on 2-inch As-doped Si(111) wafers manufactured by Siltronic, using a solid-source Riber 32P MBE system. Prior to loading the wafer into the MBE chamber, the native oxide on the Si(111) substrate is treated with a chemical solution to increase the density of nanosized pinholes for NW nucleation. To highlight the issue of reproducibility, we compare the morphology of GaAs NWs grown on two different batches of Si(111) wafers by the same manufacturer, under similar growth conditions. Fig. 1 compares the surface morphology by atomic force microscopy (AFM) of the untreated native oxide-covered Si(111) substrates from the two wafer batches, namely A and B. The rms roughness of batch A substrates is about 45% higher than that of batch B substrates. As shown in Figs. 2(a)/(d) and (b)/(e), the resultant GaAs NWs are similar in height ($\sim 1.7 \mu\text{m}$) but differ significantly in density. In order to eliminate dependency on the polishing conditions of the wafers (which affect the quality of the native oxide layer), we have developed an effective wet chemical method to create a pinhole-containing chemical oxide layer on the Si surface following native oxide removal. Using this method, we have achieved a high yield of vertical GaAs NWs exceeding 90% for NW density in the order of 10^9 cm^{-2} , as shown in Figs. (c)/(f). Finally, we investigate how the morphology and density of not only GaAs but also GaAs/III-As core-shell NWs can be controlled via the combination of chemical oxide treatment and in situ growth conditions.
