ABSTRACT Benders, such as bilayers, are well-known shape-changing structures which bend upon activation by a stimulus, such as temperature. The objective of this contribution is to propose new shape-changing rod-like structures, referred to as *twisters*, which twist upon activation. A simple biomimetic design principle based on symmetry considerations is proposed and used to derive a mechanical model. The kinematics of the response of the twister to the stimulus is inspired from FEM simulations, and slightly simplified to allow for an analytical resolution of the governing equations. Proposed twisters are shown to first stretch as the stimulus increases until a bifurcation is reached, then, they undergo a mixed stretching–twisting regime. An accurate approximation of the bifurcation point is derived and serves as a guideline for the design of twisters in accordance with chosen specifications. Results are illustrated using twisters with three different behaviours. The methodology can be straightforwardly extended to more complex kinematics and other constitutive laws.

Introduction Nature has a long experience in designing mechanical systems, offering a great source of inspiration for human-made constructions. Of particular interest in this work is the phenomena of shape change in response to an externally changing stimulus, typically humidity, present in a variety of natural systems [6]. The underlying design principle consists in the structure-function relationship of a system possessing heterogeneous expansion properties distributed throughout its shape, leading to differential expansion upon a variety of external stimuli (*activation*). This differential expansion is responsible for an overall shape change, which is referred to as *morphing*.

Among the numerous morphers present in Nature, bilayers are probably the simplest. For example, pinecones open and close depending on air moisture to release their seeds at a time favorable for their germination [5]. Metallic bilayers [11] are a well-known engineering system based on this design principle: they display bending upon activation by change of temperature (*benders*). Intrigued by twisting motions of some natural morphers such as the twist-like opening of seed pods [2] and the coiling actuation of the stork's bill awn [1], here we investigate an analogous design principle to benders leading to twisting motions activated by an external stimulus. Systems exhibiting such behaviours are referred to as *twisters*; they are to twisting what benders are to bending.

In a previous paper [12], the design of biphasic extrudable morphers following Curie's principle regarding symmetry conservation was explored using the finite-element method and revealed twisting structures. Here, a particular rotationally symmetric material architecture is more thoroughly investigated. The proposed twisters derive from qualitative observations of twisting structures simulated using the finite element method (section 1). These observations lead to a simple kinematical description which is used to propose an analytical model of twisters based on differential theory and elastic rod theory (section 2). Using the analytical methods derived in section 3, the mechanical model is shown to capture the stretching–twisting behavior of these twisters (section 4). Several illustrations are provided together with a sensitivity analysis based on approximate equations.

1. Description of twisters and qualitative analysis with FEM

We focus on translationally invariant rod-like structures (cylinders) made of two different linear elastic materials subjected to differential eigenstrains. Eigenstrains do not generate any stresses per se, but they may

lead to elastic strains because of geometric compatibility, indirectly causing elastic stresses [7]. The eigenstrains are assumed to have a linear dependency w.r.t. an externally applied stimulus, which is chosen to be constant throughout the structure.

The cross-sections are made out of a regular n -sided polygon (the core) with wings of the same shape but smaller size, placed on each side as depicted in fig. 1. The core has a low expansion coefficient (α_c) while the wings have a high expansion coefficient (α_w), thus leading to differential expansion. The circumradii of the n -sided polygons are denoted by R_c for the core and R_w for each wing. Such structures are referred to as n -twisters.

Figure 1: Rotationally symmetric concave cross-sections of twisters made out of regular n -sided polygons ($n = 3, 4, 6$). (light gray) core with a low expansion coefficient, (dark gray) wings with a high expansion coefficient.

The rationale behind such shapes is Curie’s symmetry conservation principle: “effects have at least the symmetry of their causes” [4]. In 2D, all orthogonal symmetries can be generated from mirror and rotational symmetries. Bending conserves mirror symmetry (bending plane) and benders typically possess a mirror plane. Similarly, twisting conserves rotational symmetry (rotational axis), hence the idea to look at potentially twisting structures already possessing rotational symmetry. Additionally, being translationally invariant, such structures possess the benefit of being extrudable and so are easy to process on an industrial scale.

The finite elements method was used in Abaqus® to observe the behaviour of twisters under the action of a thermal stimulus (see fig. 2 left), under free–free boundary conditions [12]. Considering large transformations (option NLgeom), the linearly elastic structure was statically loaded by a thermal scalar field, generating differential expansion. The adaptive mesh was composed of about ten thousand linear 8-node brick elements (C3D8). As the stimulus S increased, the differential expansion between the wings and the core grew. Interestingly, the morphing featured a twisting instability. For small values of S , the twister only stretched; but when S became larger than a critical value S_{crit} , its morphing became a combination of stretching and twisting ($S > S_{crit}$).

The following section is dedicated to the derivation of an analytical model for the above-described twisters, whose kinematics is inspired by the qualitative observation of the FEM simulations.

The chosen kinematic to describe the twisters deformation are derived in the framework of large strains and large displacements. Even though the methodology can be straightforwardly applied to other constitutive laws, it is however assumed that the materials of both core and wings are linear

Figure 2: Kinematical scenario based on FEM observations of the stretching-twisting instability of twisters as a function of S . (Left) Morphing stages of a 4-twister using FEM. (Right) Center lines of the core (light) and one wing (dark) in the two stages of the kinematical scenario. In the second stage ($S > S_{crit}$), the wings helically wind around the core.

elastic and undergo small strains, hence their constitutive law is given by a simple Hooke's law. The chosen kinematical scenario (see fig. 2 right) is such that:

- the core is allowed to undergo stretching and torsion, but no bending;
- the wings are constrained to wind around the core in a helical manner¹ and can thus undergo stretching as well as a combination of bending and torsion.

The center line of the wings thus follows a helix of constant radius r and constant pitch $2\pi p$ which winds around the twisted (but straight) center line of the core. The assumption that the distance between the centroids of the core and wings r is constant derives from the fact that we only impose longitudinal expansions and neglect dimensional changes in the plane of the cross-section (e.g. due to Poisson effect), as well as warping effects. More questionable is the assumption of constant pitch: in the bottom simulation of fig. 2, the twister exhibits not only i) a varying twist, but also ii) a change of sign of the twist. Noting that ii) is due to the mirror symmetry of the simulation with free-free boundary conditions, we here consider only a half-twister or, equivalently, a free-fixed twister. Regarding i), simplicity is favoured over accuracy: all the following methodology can be adapted to include a varying twist, but it would add unnecessary complications to the equations.

The elastic energy of one rod of length L with imposed longitudinal eigenstrain (ϵ^*) undergoing a combination of stretching (ϵ), single bending (κ) and torsion (τ) is given by:

$$\mathcal{E}_S(\epsilon, \kappa, \tau) = \frac{L}{2} \left(\underbrace{EA(\epsilon - \epsilon^*)^2}_{\text{stretching}} + \underbrace{EI\kappa^2}_{\text{bending}} + \underbrace{\mu J\tau^2}_{\text{torsion}} \right) \quad (2.1)$$

where E and μ are the tensile and shear moduli of its material and A , I , J the area, second moment

¹ Chirality of twisters is absent from our analytical description, hence negative and positive $\bar{\tau}$ are equivalent (handedness of helices). In practice, the twister twists in the direction determined by its initial chirality and thus “selects” one branch in the $(\bar{\epsilon}, \bar{\tau})$ space.

Nomenclature

Dimensionless parameters

A_0 Area coefficient

I_0 Inertia coefficient

J_0 Torsion coefficient

$\bar{E}$ Stiffness ratio

$\bar{\epsilon}, \bar{\tau}$ Dimensionless strain and torsion of core

$\bar{\mathcal{E}}_S$ Dimensionless energy

$\bar{\kappa}_w, \bar{\tau}_w$ Dimensionless curvature, torsion of wing

$\bar{R}$ Size ratio

$\bar{R}_c$ Dimensionless core circumradius

$\bar{R}_w$ Dimensionless core circumradius

Geometric parameters

$2\pi p$ Pitch of the helix

A_c, A_w Cross-sectional area of core, wing

ϵ_c, ϵ_w Longitudinal strain of core, wing

$\epsilon_c^*, \epsilon_w^*$ Imposed eigenstrain on core, wing

I_c, I_w Second moment of area of core, wing

J_c, J_w Torsion constant of core, wing

κ_c, κ_w Curvature of core, wing

L_c, L_w Length of core, wing

n Number of wings

R_c, R_w Circumradius of core, wing

τ_c, τ_w Torsion of core, wing

L_0 Length of twister at rest

r Distance between centroids of core and wings

Material parameters

α_c, α_w Expansion coefficient of core, wing

$\Delta\alpha$ The differential expansion coefficient

E_c, E_w Young modulus of core, wing

ν_c, ν_w Poisson coefficient of core, wing

Other parameters

$\mathcal{E}_S$ Total elastic energy

$\mathcal{E}_{\text{core}}$ Elastic energy of the core

$\bar{\epsilon}_{\text{crit}}$ Strain of core at instability

$\mathcal{E}_{\text{wing}}$ Elastic energy of one wing

S_{crit} External stimulus at instability

S External stimulus

of area and torsion constant² of its cross-section. The action of the stimulus is described as an “eigenstretching” of the core and the wings via the imposed eigenstrain ϵ^* , controlled by the external stimulus S via $\epsilon_\bullet^* = \alpha_\bullet S$ where $\alpha_\bullet$ is the susceptibility to the external stimulus S ($\bullet \in \{c, w\}$). For example, the external stimulus can be a variation of temperature $S = \Delta T$ and α would then be the coefficient of thermal expansion. According to our kinematical scenario, the energy of the core $\mathcal{E}_{\text{core}}$ is a function of its stretching ϵ_c and its torsion τ_c , and the energy of each wing $\mathcal{E}_{\text{wing}}$ is a function of its stretching ϵ_w , its curvature bending κ_w and its torsion τ_w . Because of the kinematical assumptions, the quantities $\epsilon_c, \tau_c, \epsilon_w, \kappa_w$ and τ_w are constant along the twister’s main axis. Considering isotropic materials ($\mu_\bullet = E_\bullet/2(1 + \nu_\bullet)$), we have:

$$\mathcal{E}_{\text{core}}(\epsilon_c, \tau_c) = \frac{L_c E_c}{2} \left(A_c (\epsilon_c - \epsilon_c^*)^2 + \frac{J_c}{2(1 + \nu_c)} \tau_c^2 \right), \quad (2.2)$$

and

$$\mathcal{E}_{\text{wing}}(\epsilon_w, \kappa_w, \tau_w) = \frac{L_w E E_w}{2} \left(A_w (\epsilon_w - \epsilon_w^*)^2 + I_w \kappa_w^2 + \frac{J_w}{2(1 + \nu_w)} \tau_w^2 \right), \quad (2.3)$$

where L_c and L_w denote the length of the center line of the core and wing respectively. The total energy $\mathcal{E}_S = \mathcal{E}_{\text{core}} + n\mathcal{E}_{\text{wing}}$ together with the proposed kinematics embed enough “information” to achieve the targeted twisting upon activation above a stimulus threshold S_{crit} . To support this claim, $\mathcal{E}_S$ is now going to be derived in the case of the previously introduced polygonal geometries.

The chosen kinematics can first be used to reduce the number of parameters. Introducing the dimensionless torsion of the core $\bar{\tau} = r\tau_c = r d\theta/dz = r/p$ and given that the arclength variation of an helix of radius r and pitch p is related to the variation of its azimuthal angle along the transversal

² The torsion constant should not be confused with the polar moment of inertia, which are only equal for circular shapes. More details are given in appendix A.4.

direction θ by $ds = \sqrt{r^2 + p^2} d\theta$, the length of the core (L_c) and the length of a wing (L_w) are related by:

$$L_c = \int_0^{L_c} dz = p \int_0^{\frac{L_c}{p}} d\theta = \frac{p}{\sqrt{r^2 + p^2}} \int_0^{L_w} ds = \frac{L_w}{\sqrt{1 + \bar{\tau}^2}}. \quad (2.4)$$

The relation between L_c and L_w therefore only involves $\bar{\tau}$. In line with the notation $\bar{\tau}$ for the dimensionless torsion of the core, we introduce the notation $\bar{\epsilon} = \epsilon_c$ for the dimensionless stretching of the core. In the framework of large transformations [3, sec. 2.2], the stretching of the wings (ϵ_w) and the stretching of the core (ϵ_c) are defined as:

$$\epsilon_w = \frac{\left(\frac{L_w}{L_0}\right)^2 - 1}{2} \quad \text{and} \quad \bar{\epsilon} = \epsilon_c = \frac{\left(\frac{L_c}{L_0}\right)^2 - 1}{2}, \quad (2.5)$$

where L_0 denotes the initial length of the twister. If $|L_\bullet - L_0| \ll L_0$, this reduces to $\epsilon_\bullet = (L_\bullet - L_0)/L_0$. Using eq. (2.4) yields the following relation between ϵ_c and ϵ_w :

$$\epsilon_w = \frac{\left(\frac{L_w}{L_0}\right)^2 - 1}{2} = \frac{(1 + \bar{\tau}^2) \left(\frac{L_c}{L_0}\right)^2 - 1}{2} = \bar{\epsilon}(1 + \bar{\tau}^2) + \frac{1}{2}\bar{\tau}^2. \quad (2.6)$$

Assuming perfect attachment between the wings and the core (as required by the compatibility of strain before delamination), the material curvature and torsion of the wings can be assimilated to the geometric curvature and torsion of their center line helix defined by $\kappa_w = r/(r^2 + p^2)$ and $\tau_w = p/(r^2 + p^2)$ respectively. In their chosen dimensionless form, the material curvature and torsion of the wings are:

$$\bar{\kappa}_w = r\kappa_w = \frac{\bar{\tau}^2}{1 + \bar{\tau}^2}, \quad \bar{\tau}_w = r\tau_w = \frac{\bar{\tau}}{1 + \bar{\tau}^2}. \quad (2.7)$$

Finally, the material curvature of the core is zero ($\kappa_c = 0$, straight line). The proposed helical morphing scenario is hence such that all geometric variables (lengths, stretchings, curvatures and torsions) can be expressed as functions of L_c , $\bar{\epsilon}$ and $\bar{\tau}$ using eq. (2.4), eq. (2.6), eq. (2.7). The configuration of a n -twister for a given stimulus, which is *a priori* parametrized by the eight geometric quantities L_c , L_w , ϵ_c , ϵ_w , κ_c , κ_w , τ_c and τ_w , is thus entirely determined by the stretching and torsion of its core ($\bar{\epsilon}$ and $\bar{\tau}$) – and of course by the initial geometry governed by n , L_0 , R_c and R_w as well as the material properties E_c , E_w , ν_c , ν_w , α_c and α_w . This implies that the elastic energy of the whole twister is a function of $\bar{\epsilon}$ and $\bar{\tau}$ only. Using the terminology of catastrophe theory [10], n , L_0 , R_c and R_w as well as E_c , E_w , ν_c , ν_w , α_c and α_w are *control parameters*, while $\bar{\epsilon}$ and $\bar{\tau}$ are *state variables*.

The energy of one wing becomes:

$$\begin{aligned} \mathcal{E}_{\text{wing}}(\bar{\epsilon}, \bar{\tau}) = \sqrt{1 + \bar{\tau}^2} \frac{L_c E_w}{2} & \left(A_w \left(\bar{\epsilon}(1 + \bar{\tau}^2) + \frac{1}{2}\bar{\tau}^2 - \epsilon_w^* \right)^2 \right. \\ & \left. + I_w \left(\frac{\bar{\tau}^2}{r(1 + \bar{\tau}^2)} \right)^2 + \frac{J_w}{2(1 + \nu_w)} \left(\frac{\bar{\tau}}{r(1 + \bar{\tau}^2)} \right)^2 \right). \end{aligned} \quad (2.8)$$

Using, for sake of simplicity, the additional assumption that the two materials have the same Poisson

ratio ($\nu_c = \nu_w = \nu$), the energy of a n -twister consisting of one core and n wings is such that:

$$\mathcal{E}_S(\bar{\epsilon}, \bar{\tau}) = \overbrace{\frac{E_c L_c}{2} A_c (\bar{\epsilon} - \epsilon_c^*)^2}^{\text{stretching of the core}} + \overbrace{\frac{E_c L_c}{4} \frac{J_c}{r^2(1+\nu)} \bar{\tau}^2}^{\text{torsion of the core}} +$$

$$n \frac{E_w L_c \sqrt{1+\bar{\tau}^2}}{2} \left[\underbrace{A_w \left(\bar{\epsilon}(1+\bar{\tau}^2) + \frac{1}{2}\bar{\tau}^2 - \epsilon_w^* \right)^2}_{\text{stretching of one wing}} + \underbrace{I_w \left(\frac{\bar{\tau}^2}{r(1+\bar{\tau}^2)} \right)^2}_{\text{bending of one wing}} + \underbrace{\frac{J_w}{2(1+\nu)} \left(\frac{\bar{\tau}}{r(1+\bar{\tau}^2)} \right)^2}_{\text{torsion of one wing}} \right]. \quad (2.9)$$

The area, second moment of area and torsion constant are given by $A_\bullet = A_0 R_\bullet^2$, $I_\bullet = I_0 R_\bullet^4$ and $J_\bullet = J_0 R_\bullet^4$, where A_0 , I_0 and J_0 are geometric parameters depending only on the shape (governed by n). The analytical expressions of $A_0(n)$ and $I_0(n)$ are derived in appendix A, where the approximated values of J_0 for $n \in \{3, 4, 6\}$ are also given. It is worth noting that with the chosen kinematics, each wing deforms w.r.t. its neutral axis, not the twister's, so that each second moment of area needs to be calculated for an axis passing through the centroid of its polygon, and not the centroid of the twister. Additionally, second moment of inertia of sections with at least three axes of symmetry do not depend on the direction of the axis they are calculated with [8]. This holds in particular for all regular polygons and simplifies the calculation in the present case.

Observing that $L_c = L_0 \sqrt{1+2\bar{\epsilon}}$ (from eq. (2.5)), adding S as an explicit parameter and introducing the stiffness ratio $\bar{E} = E_c/E_w$ as well as the dimensionless core and wing circumradii $\bar{R}_c = R_c/r$ and $\bar{R}_w = R_w/r$, the dimensionless scaled elastic energy ($\bar{\mathcal{E}}_S = 2\mathcal{E}_S/(L_0 E_w R_w^2)$) is finally given by:

$$\bar{\mathcal{E}}_S(\bar{\epsilon}, \bar{\tau}) = \sqrt{1+2\bar{\epsilon}} \left[\bar{E} \frac{\bar{R}_c^2}{\bar{R}_w^2} \left(A_0 (\bar{\epsilon} - \alpha_c S)^2 + \frac{\bar{R}_c^2}{2} \frac{J_0}{(1+\nu)} \bar{\tau}^2 \right) + \right.$$

$$\left. n \sqrt{1+\bar{\tau}^2} \left(A_0 \left(\bar{\epsilon}(1+\bar{\tau}^2) + \frac{1}{2}\bar{\tau}^2 - \alpha_w S \right)^2 + \bar{R}_w^2 \left(I_0 \frac{\bar{\tau}^4}{(1+\bar{\tau}^2)^2} + \frac{J_0}{2(1+\nu)} \frac{\bar{\tau}^2}{(1+\bar{\tau}^2)^2} \right) \right) \right]. \quad (2.10)$$

3. Characterisation of the twister's response

The expression of the energy (eq. (2.10)) can be used to compute the response of a twister to a stimulus S by minimising $\bar{\mathcal{E}}_S$ with respect to $\bar{\epsilon}$ and $\bar{\tau}$. This could be done numerically, but the optimisation problem can be simplified with the use of optimality conditions. Necessarily, an equilibrium point $(\bar{\epsilon}, \bar{\tau})$ is a stationary point of $\bar{\mathcal{E}}_S$, that is $\nabla \bar{\mathcal{E}}_S = 0$ or equivalently:

$$\begin{cases} \partial_{\bar{\epsilon}} \bar{\mathcal{E}}_S(\bar{\epsilon}, \bar{\tau}) = 0, \\ \partial_{\bar{\tau}} \bar{\mathcal{E}}_S(\bar{\epsilon}, \bar{\tau}) = 0. \end{cases} \quad (3.1)$$

$$\quad (3.2)$$

The evolution of a twister starting from its resting position $(\bar{\epsilon}, \bar{\tau}) = (0, 0)$ for $S = 0$ is now considered. Since eq. (3.2) is always satisfied for $\bar{\tau} = 0$ (because the energy is an even function of $\bar{\tau}$), the response of a twister to the stimulus S is governed³ only by eq. (3.1), as long as no critical point of $\partial_{\bar{\tau}} \bar{\mathcal{E}}_S$ is reached. Equation (3.1) with $\bar{\tau} = 0$ constitutes the governing law of the stretching phase, by providing the strain $\bar{\epsilon}$ induced by the stimulus. In order to perform a qualitative analysis, $\partial_{\bar{\epsilon}} \bar{\mathcal{E}}_S(\bar{\epsilon}, 0) = 0$ can be approximated by using a first-order Taylor expansion in $\bar{\epsilon}$ in the

³ This necessary condition is also a sufficient condition because the energy is locally convex at $(\bar{\epsilon}, \bar{\tau}) = (0, 0)$ for $S = 0$ (the determinant of the Hessian matrix of $\bar{\mathcal{E}}_0(0, 0)$ is positive), and because it remains convex until $(\bar{\epsilon}, \bar{\tau})$ becomes a critical point of $\partial_{\bar{\tau}} \bar{\mathcal{E}}_S$.

neighbourhood of 0 (legitimized by the small strains assumption $\bar{\epsilon} \ll 1$). Expressing $\bar{\epsilon}$ in terms of S yields:

$$\bar{\epsilon} \approx \frac{\alpha_w n + \alpha_c \bar{E} \bar{R}^2}{n + \bar{E} \bar{R}^2} S = \left(\alpha_w - \frac{\Delta \alpha}{1 + n/(\bar{E} \bar{R}^2)} \right) S, \quad (3.3)$$

where $\bar{R} = R_c/R_w = \bar{R}_c/\bar{R}_w$ is the size ratio and $\Delta \alpha = \alpha_w - \alpha_c$ is the differential expansion coefficient. The strains of core and wings are the same in the stretching phase ($\epsilon_w = \epsilon_c = \bar{\epsilon}$ from eq. (2.6) with $\bar{\tau} = 0$) and can be approximated by eq. (3.3). The core is not twisting ($\tau_c = 0$) and the wings are thus neither bending nor twisting ($\tau_w = \kappa_w = 0$ from eq. (2.7) with $\bar{\tau} = 0$). Equation (3.3) shows that when $E_c \rightarrow \infty$ or $R_c \rightarrow \infty$, the behaviour is dominated by the core ($\bar{\epsilon} \sim \alpha_c S$), which is relevant. On the contrary, when $n \rightarrow \infty$, the behavior follows the stretching of the wings ($\bar{\epsilon} \sim \alpha_w S$). We can also check that the stretching increases with α_w , as expected.

Now that the stretching phase has been characterized, the question is whether the proposed candidate is *actually* a twister. In other words, is there a value S_{crit} such that the system starts twisting when the stimulus reaches S_{crit} ? This boils down to whether $\partial_{\bar{\tau}} \bar{\mathcal{E}}_S(\bar{\epsilon}, 0)$ reaches a critical point, i.e.:

$$\begin{cases} \partial_{\bar{\tau}}^2 \bar{\mathcal{E}}_S(\bar{\epsilon}, 0) = 0, \\ \partial_{\bar{\tau} \bar{\tau}}^2 \bar{\mathcal{E}}_S(\bar{\epsilon}, 0) = 0, \end{cases} \quad (3.4)$$

$$(3.5)$$

for some $\bar{\epsilon}$. Equation (3.4) is satisfied for all $\bar{\epsilon}$ and S , because it equals $\partial_{\bar{\tau}}^2 \bar{\mathcal{E}}_S$ which is the derivative w.r.t. $\bar{\tau}$ of an even function of $\bar{\tau}$. The existence of a critical point is thus governed by eq. (3.1) (stretching phase) and eq. (3.5) (critical point). Though very simple to solve numerically, this reduces to a system of two independent quadratic equations in $\bar{\epsilon}$ and S , which does not have closed-form solutions that can be reasonably apprehended. For the sensitivity analysis to come in section 4, we linearize eq. (3.1) as previously, leading to eq. (3.3). This expression of $\bar{\epsilon}$ is then injected into eq. (3.5) which provides the following expression of the critical stimulus:

$$S_{\text{crit}} \approx (n + \bar{E} \bar{R}^2) \frac{\sqrt{1 + AB(n + \bar{E} \bar{R}^4) \bar{R}_c^2} - 1}{A}, \quad (3.6)$$

with $A = 4\alpha_w n + (5\alpha_c - \alpha_w) \bar{E} \bar{R}^2 = 4\alpha_w(n + \bar{E} \bar{R}^2) - 5\Delta \alpha \bar{E} \bar{R}^2$ and $B = J_0(A_0 \Delta \alpha n(1 + \nu) \bar{E} \bar{R}^4)^{-1}$. The corresponding $\bar{\epsilon}_{\text{crit}}$ can be easily retrieved using eq. (3.3):

$$\bar{\epsilon}_{\text{crit}} \approx (\alpha_w n + \alpha_c \bar{E} \bar{R}^2) \frac{\sqrt{1 + AB(n + \bar{E} \bar{R}^4) \bar{R}_c^2} - 1}{A}. \quad (3.7)$$

When $\alpha_w \rightarrow \alpha_c$ ($\Delta \alpha \rightarrow 0$), $B \rightarrow \infty$ and we have $S_{\text{crit}} \rightarrow \infty$ as well as $\bar{\epsilon}_{\text{crit}} \rightarrow \infty$, meaning that the critical point is not reachable. This is relevant: there is no differential expansion, hence no twist. Cases $\bar{E} \rightarrow \infty$ or $\bar{E} \rightarrow 0$ (core or wings become infinitely rigid) and $n \rightarrow \infty$ (axisymmetric structure) also lead to $S_{\text{crit}} \rightarrow \infty$ and $\bar{\epsilon}_{\text{crit}} \rightarrow \infty$, as expected. We insist that the approximation provided by eq. (3.6) does not formally prove the existence of a bifurcation: it is not excluded that the approximation of S_{crit} exists for a given set of geometric and material parameters, while the exact system of equations has no solutions for the same set of parameters, meaning there is no critical point. The tedious case by case discussion would not bring much: what matters is that for a very large majority of parameters, i) there is a critical point and ii) it is well approximated by eq. (3.6) and eq. (3.7). Both i) and ii) will be illustrated in the next section, demonstrating that the proposed mechanical system is an actual twister.

The post-instability evolution ($S > S_{\text{crit}}$) remains to be characterised. As for the stretching phase, the governing equations are eqs. (3.1) and (3.2). However, now $\bar{\tau} \neq 0$ so the second equation

is not always satisfied: both equations are necessary⁴. Equations (3.1) and (3.2) can easily be solved numerically; they can also be approximated locally using Taylor expansions, but it is not useful for the discussion. More interesting is the limit value of $\bar{\tau}$ as the stimulus increases. Solving eq. (3.2) for S and injecting the result into eq. (3.1) for $\bar{\epsilon} \rightarrow \infty$ leads to the asymptotic values of $\bar{\tau}$:

$$\lim_{\bar{\epsilon} \rightarrow \infty} \bar{\tau} = \pm \sqrt{\frac{\Delta\alpha}{\alpha_c}}. \quad (3.8)$$

This limit shows that as the stimulus increases in the stretching & twisting regime, the torsion asymptotically reaches a value which *only* depends on the expansion coefficients α_c and α_w . This provides a very simple way of estimating the maximum twist.

In this section, the governing equations of the stretching and stretching–twisting phases, summarized in table 1, have been given. They are used and illustrated in the following section.

Regime	Kinematical scenario	Governing equation(s)	Approximated solution
Stretching	$\begin{cases} \epsilon_c = \epsilon_w = \bar{\epsilon} \\ \tau_c = \tau_w = 0 \end{cases}$	$\partial_{\bar{\epsilon}} \bar{\mathcal{E}}_S(\bar{\epsilon}, 0) = 0$	$\bar{\epsilon}$ given in eq. (3.3)
Bifurcation	$\begin{cases} \epsilon_c = \epsilon_w = \bar{\epsilon} \\ \tau_c = \tau_w = 0 \end{cases}$	$\begin{cases} \partial_{\bar{\epsilon}} \bar{\mathcal{E}}_S(\bar{\epsilon}, 0) = 0 \\ \partial_{\bar{\tau}}^2 \bar{\mathcal{E}}_S(\bar{\epsilon}, 0) = 0 \end{cases}$	$\bar{\epsilon} = \bar{\epsilon}_{\text{crit}}$ given in eq. (3.7)
Stretching & twisting	$\begin{cases} \epsilon_c = \bar{\epsilon} \neq \epsilon_w \text{ (eq. (2.6))} \\ \tau_c = \frac{\bar{\tau}}{r} \neq \tau_w \text{ (eq. (2.7))} \end{cases}$	$\begin{cases} \partial_{\bar{\epsilon}} \bar{\mathcal{E}}_S(\bar{\epsilon}, \bar{\tau}) = 0 \\ \partial_{\bar{\tau}} \bar{\mathcal{E}}_S(\bar{\epsilon}, \bar{\tau}) = 0 \end{cases}$	$\begin{cases} \bar{\epsilon} \rightarrow \infty \\ \bar{\tau} \rightarrow \pm \frac{\Delta\alpha}{\alpha_c} \end{cases}$

Table 1: Summary of the equations governing the response of the twister to the stimulus S .

4. Results and discussion

The governing equations of the twister in both stretching and stretching–twisting regimes have been provided and approximated in the previous section. These expressions are now used to design twisters in accordance with some technical specifications. The design possibilities are illustrated for four different twisters:

- Twister 0 (T0) is a reference twister with arbitrary parameters;
- Twister 1 (T1) should stretch more than T0 and twist with a smaller amplitude;
- Twister 2 (T2) should stretch less than T0 and twist with a larger amplitude;
- Twister 3 (T3) should stretch more than T0 and twist with a larger amplitude.

The sensitivity of S_{crit} and $\bar{\epsilon}_{\text{crit}}$ to the parameters values is analysed using eqs. (3.6) and (3.7). The sign of the variation of S_{crit} for a small change of the parameters around their reference values (see table 3, line T0) is reported in table 2. For the chosen reference values the sign of the variation of $\bar{\epsilon}_{\text{crit}}$ is the same as the sign of variation of S_{crit} . The relevance of the result of the sensitivity analysis is detailed for each parameter in the third column.

⁴For the stretching phase, there were one equation for two unknowns ($\bar{\tau} = 0$): solutions are, generically, curves. For the twisting phase, there are two equations for the three unknowns $\bar{\epsilon}$, $\bar{\tau}$ and S , so the solutions are also curves: the additional variable $\bar{\tau}$ is “compensated” by the additional equation $\partial_{\bar{\tau}} \bar{\mathcal{E}}_S$.

Increasing Parameter	Variation of S_{crit} and $\bar{\epsilon}_{\text{crit}}$	Comments on relevance
n	$\nearrow$	As n increases, the twister gets closer to an axisymmetric structure, which does not twist.
$\bar{E}$	$\nearrow$	Increasing the stiffness of the core results in a higher resistance to twist.
ν	$\searrow$	When the Poisson's ratio increases, the twisting stiffness decreases relatively to the stretching stiffness, thus lowering the resistance to twist.
$\bar{R}$	$\nearrow$	Increasing the relative volume of the core results in a higher resistance to twist.
$\Delta\alpha = \alpha_w - \alpha_c$	$\searrow$	Increasing the differential expansion pushes twisting to activate sooner.

Table 2: Variations of S_{crit} and $\bar{\epsilon}_{\text{crit}}$ for small increases of the parameters around their reference values. An arrow $\nearrow$ for a parameter indicates that S_{crit} and $\bar{\epsilon}_{\text{crit}}$ increases when the parameter increases, meaning that the twister becomes less favorable to twisting.

Table 2 serves as a guideline for the design of T1, T2 and T3 by adjusting the parameters of T0. T1 should i) twist for large value of $\bar{\epsilon}_{\text{crit}}$ and ii) the post-instability twisting amplitude should be small. Equation (3.8) shows ii) can only be achieved with a small difference of expansion coefficients $\Delta\alpha$, compared to α_c . Specification i) can be enhanced by increasing $\bar{E}$, for example. For T2, a similar reasoning leads to a reduction of $\bar{R}$ and an increase of $\Delta\alpha$ while T3 is set by increasing $\bar{E}$ as well as the differential expansion $\Delta\alpha$. The selected values are reported in table 3.

Twister	n	$\bar{E}$	ν	R_c	R_w	α_c	α_w
T0	3	3	0	3	2	0.4	0.5
T1	3	4	0	3	2	0.4	0.41
T2	3	3	0	1	1	0.5	1
T3	3	300	0	3	2	0.4	0.8

Table 3: Parameter values of the four twisters.

The critical values of the instability have been computed by solving equations (3.1) and (3.5) (see table 1) and are compared to the approximate equations provided in section 2. For all cases, such critical values exist: this means that the proposed model actually describes a twisting instability. Moreover, the approximations of S_{crit} and $\bar{\epsilon}_{\text{crit}}$ are very close to the computed values, which validates eq. (3.6) and eq. (3.7), as well as the approximate description of the stretching phase.

The state evolution of a twister in response to an increasing stimulus results from the simple numerical resolution of the governing equations (cf. table 1). All numerical results were computed in Mathematica. Figure 3 depicts the results for each chosen twister. The asymptotes directly follow from eq. (3.8). For each case, the observed behaviour is consistent with the FEM simulations: stretching regime, then instability giving birth to a stretching–twisting regime. Branches are symmetric with respect to $\bar{\tau}$ but negative branches have not been represented. It is worth mentioning that, contrary to the small strain assumption, the strains around the twisting instability can be

Twister	“Exact” value		Approximation		Relative error	
	S_{crit}	$\bar{\epsilon}_{\text{crit}}$	S_{crit}	$\bar{\epsilon}_{\text{crit}}$	S_{crit}	$\bar{\epsilon}_{\text{crit}}$
T0	1.61	0.694	1.60	0.689	0.6 %	0.7 %
T1	6.83	2.75	6.84	2.75	0.1 %	0.0 %
T2	0.383	0.285	0.391	0.293	1.9 %	2.9 %
T3	8.72	3.50	8.72	3.50	0.0 %	0.0 %

Table 4: Comparison of the critical values of $\bar{\epsilon}$ and S causing bifurcations for the four twisters.

relatively high, thus contradicting Hook’s law. However, the same qualitative behavior is expected with an adapted large deformation behavior law. In the end, the proposed mechanical model, though simple, proves to exhibit the targeted twisting behaviour.

Figure 3: State evolutions of the twisters of table 3. [.....] T0, [—] T1, [—] T2, [—] T3. Dashed lines: asymptotes of $\bar{\tau}$ for $\bar{\epsilon} \rightarrow \infty$. Negative $\bar{\tau}$ have been omitted.

The critical value S_{crit} plays the same role as the critical force in buckling theory: exactly as a beam subjected to an increasing normal force buckles in one direction when the force is sufficiently high, twisters subjected to an increasing stimulus twists in one direction ($\pm\bar{\tau}$) when the stimulus is sufficiently high. Animations of the four twisters are provided as supplementary material. Illustrations of the centroids of the core and one wing are provided in fig. 4 for the three twisters T1, T2 and T3.

Conclusion Inspired by Nature and based on symmetry considerations, a particular class of structures called *twisters* was proposed featuring open rotational symmetric cross-sections made out of regular polygons, where active wings are arranged around a passive core. A twister reacts to an external stimulus, such as a uniform temperature field, by differential expansion leading to a combination of stretching and twisting. A kinematical scenario based on FEM simulations was derived and used to construct a mechanical model with two state variables (the stretching strain and the twist). Governing equations were provided and it was shown that the evolution of the response to the stimulus featured a twisting instability: above a critical value of the stimulus S_{crit} , the twister’s morphing behavior changes from a pure stretching regime to a stretching & twisting regime. An approximation of S_{crit} was derived and set the base for a simple sensitivity analysis. The latter was

(a) T1: long stretching phase, small twisting amplitude. (b) T2: small stretching phase, large twisting amplitude. (c) T3: long stretching phase, large twisting amplitude.

Figure 4: Centroids of the core (light gray) and of one wing (red) for different levels of stimulus S . Each row corresponds to the same stimulus and all images share the same scale. Corresponding animations are available online.

used to choose the value of twisters parameters in accordance with some arbitrary specifications. Numerical simulations validated the design principle of the twister and the approximated value of S_{crit} was shown to be very accurate. In the end, we now have a new simple structure, capable of responding to a uniform stimulus by stretching and twisting. The assumptions of constant twist and linear elastic materials were useful to derive understandable formulas and check their relevance. However, the presented methodology can be easily extended to more general kinematic scenarii or other constitutive laws.

By combining benders and twisters, it is theoretically possible to build rod-like morphers morphing into any curve in space as a stimulus increases. This new marterial architecture thus enriches the existing design space of passive actuators. The main remaining challenge now lies in the choice of appropriate material.

Author contributions statement S.T. conceived the study, formulated the mechanical model and contributed to about half of the manuscript. A.T. solved the mechanical model and contributed to about half of the manuscript. J.D, Y.B. and P.F. helped to concieve the study.

A. Geometric relationships

Figure 5: Cross-section of a n -twister and related notations.

A.1. Relation between r , R_c and R_w Geometric relationships can be easily derived by considering triangular slices of n -sided regular polygons, see fig. 5. Using elementary geometry:

$$r^2 = \|\vec{OC}\|^2 = \|\vec{OA} + \vec{AC}\|^2 = \|R_c(1, 0) + R_w(\cos(\alpha), \sin(\alpha))\|^2 = (R_c + R_w \cos(\alpha))^2 + (R_w \sin(\alpha))^2,$$

so, with $\bar{R} = R_c/R_w$ and since $\alpha = 2\pi/n$, we have:

$$r = \sqrt{R_c^2 + 2R_cR_w \cos\left(\frac{2\pi}{n}\right) + R_w^2} = R_w \sqrt{1 + 2\bar{R} \cos\left(\frac{2\pi}{n}\right) + \bar{R}^2}. \quad (\text{A.1})$$

A.2. Expression of $A_0(n)$ The areas of the core and of one wing are given by $A_c = A_0(n)R_c^2$ and $A_w = A_0(n)R_w^2$ where $A_0(n)$ is the area of a n -sided regular polygon of unit circumradius. Considering the triangle above, it comes directly:

$$A_c(n) = \frac{1}{2}n \times OA \times OB \sin(\alpha) = \frac{n}{2}R_c^2 \sin(\alpha). \quad (\text{A.2})$$

so finally $A_0(n) = \frac{1}{2}n \sin(2\pi/n)$ (note that $A_0 \rightarrow \pi$ when $n \rightarrow \infty$: it's the area of a unit disk).

A.3. Expression of $I_0(n)$ Without loss of generality, the n -sided regular polygon is assumed to be such that the vertices A_k have coordinates $(\cos(2\pi k/n), \sin(2\pi k/n))$, for $k \in \{1, \dots, n\}$ and $A_{n+1} = A_1$. Then, the expression of the second moment of area with respect⁵ to the y -axis is given by [8]:

$$I_y = \frac{1}{12} \sum_{k=1}^n (x_k^2 + x_k x_{k+1} + x_{k+1}^2) (x_k y_{k+1} - x_{k+1} y_k).$$

Using trigonometric identities, this expression simplifies nicely. The right parenthesis becomes:

$$x_k y_{k+1} - x_{k+1} y_k = \cos\left(\frac{2k\pi}{n}\right) \sin\left(\frac{2(k+1)\pi}{n}\right) - \cos\left(\frac{2(k+1)\pi}{n}\right) \sin\left(\frac{2k\pi}{n}\right) = \sin\left(\frac{2\pi}{n}\right),$$

⁵ The second moment of area does not depend on the direction of the axis for regular polygonal sections.

so it does not depend on k and can factorize the sum. Then,

$$\sum_{k=1}^n x_k^2 = \sum_k x_{k+1}^2 = \frac{1}{2} \sum_{k=1}^n \left(1 + \cos \left(\frac{4k\pi}{n} \right) \right) = \frac{n}{2},$$

and using the identity $\cos(a) \cos(a+b) = (\cos(b) + \cos(2a+b))/2$ it comes:

$$\sum_{k=1}^n x_k x_{k+1} = \sum_{k=1}^n \frac{1}{2} \left(\cos \left(\frac{2\pi}{n} \right) + \cos \left(\frac{4k\pi}{n} + \frac{2\pi}{n} \right) \right) = \frac{1}{2} n \cos \left(\frac{2\pi}{n} \right).$$

Finally,

$$I_0(n) = \frac{n}{12} \sin \left(\frac{2\pi}{n} \right) \left(1 + \frac{1}{2} \cos \left(\frac{2\pi}{n} \right) \right). \quad (\text{A.3})$$

$I_0(n) \rightarrow \frac{1}{4}\pi$ when $n \rightarrow \infty$, which corresponds to the second moment of area of a unit disk.

A.4. Expression of $J_0(n)$ In general, there is no closed-form expressions of the torsion constant $J_0(n)$. Following Saint-Venant's solution for uniform twist [3, sec. 3.4], one has to solve a Poisson equation on the potential $\chi(x, y)$ from which the shear strain vector field $-\epsilon_{yz}\mathbf{e}_x + \epsilon_{xz}\mathbf{e}_y$ with zero curl derives. By defining a rescaled potential $\bar{\chi} = \frac{\chi}{\tau}$ and having solved $\bar{\chi}$ for a particular cross-section, the torsion constant is given by:

$$J = 4 \iint_D (\bar{\chi}_{,x}^2 + \bar{\chi}_{,y}^2) dx dy. \quad (\text{A.4})$$

A.5. Values for $n \in \{3, 4, 6\}$ Numerical approximations of $J_0(n)$ are given in table 5 for the considered geometries [9].

side number n_w	shape	area $A_\bullet = A_0 R_\bullet^2$	second moment of area $I_\bullet = I_0 R_\bullet^4$	torsion constant $J_\bullet = J_0 R_\bullet^4$
3		$A_0 = \frac{3\sqrt{3}}{4} \approx 1.30$	$I_0 = \frac{3\sqrt{3}}{32} \approx 0.162$	$J_0 = \frac{9\sqrt{3}}{80} \approx 0.195$
4		$A_0 = 2.00$	$I_0 = \frac{1}{3} \approx 0.333$	$J_0 \approx 0.563$
6		$A_0 = \frac{3\sqrt{3}}{2} \approx 2.60$	$I_0 = \frac{5\sqrt{3}}{16} \approx 0.541$	$J_0 \approx 1.04$

Table 5: Values of the geometric parameters of regular n -sided polygons ($n = 3, 4, 6$ and $\bullet \in \{c, w\}$).
