Abstract

We consider electromagnetic wave propagation in domains constituted by thin coaxial cables (made of a dielectric material which surrounds a metallic inner-wire) and a small junction. The goal is to trim down 3D Maxwell’s equations in this complicated geometry to a quantum graph (see [3]) in which, along each edge, one is reduced to compute the electrical potential and current a by solving wave equations (the telegrapher’s model) coupled by vertex conditions. In this work, using the method of matched asymptotics, we propose improved Kirchhoff conditions and we give a rigorous justification of such a model reduction.

Keywords: Maxwell’s equations, telegrapher’s equation, matched asymptotics, quantum graph.

1 The geometry

We consider a domain Ωδ, with δ > 0, which is homothetic to a (unbounded) reference domain namely

\[ Ω^δ = δ Ω^1 \]  

as described in Figure 1 where Ω^1 is the connected union of (L + 1) semi-infinite cables Ω^1_ℓ (ℓ = 0...L) and a bounded junction J^1 as illustrated by Figure 1. More precisely, each Ω_ℓ is isomorphic to S^ℓ × R_+, where S_ℓ is a non simply connected bounded domain of R^2 with one single hole. The ”small” parameter δ refers to the thinness of the propagation domain. When δ → 0, Ω^δ converges to a graph G, union of L half-lines D_ℓ. In the following, we denote x^δ_3 ≥ 0 the abscissa along D_ℓ and x^δ_T = (x^δ_3, x^δ_T) associ-

![Figure 1: The reference domain Ω^1 (center) the limit graph G (right) and a cross-section S_ℓ (left)](image)

ated transverse coordinates.

\[ Ω^δ_ℓ = \{(δ x^δ_T, x^δ_3) | (x^δ_T, x^δ_3) ∈ Ω^1_ℓ}\} \]

We are interested in the solution (E^δ, H^δ) of lossy 3D-Maxwell’s equations in this domain, with constant coefficients for simplicity, and perfectly conducting boundary conditions along ∂Ω^δ. More precisely we wish to describe the behavior of this solution for small δ from the solution of a 1D “effective model” on the limit graph.

2 The reduced model

We describe below only the behavior of the electromagnetic fields in the (L + 1) cables:

\[ E^δ(x^δ_T, x^δ_3, t) \sim V^δ_ℓ(x^δ_3, t) \nabla ϕ^δ_ℓ \left( \frac{x^δ_T}{δ} \right) \]

\[ H^δ(x^δ_T, x^δ_3, t) \sim I^δ_ℓ(x^δ_3, t) \nabla ψ^δ_ℓ \left( \frac{x^δ_T}{δ} \right) \]  

(2)
where the harmonic potentials $\varphi^\ell$ and $\psi^\ell$ are defined by elliptic problems in $S^\ell$ (see [1]). The electrical potential $V^\ell$ and current $I^\ell$ are solutions of the telegrapher’s equation (equation (4)\(\partial_t \equiv \partial/\partial x^3\)):

\[
\begin{cases}
(C^\ell \partial_t + G^\ell) \mathbf{V}^\ell + \partial_t \mathbf{I}^\ell = 0, \\
(L^\ell \partial_t + R^\ell) \mathbf{I}^\ell = 0,
\end{cases}
\text{ on } D^\ell
\] (3)

where $C^\ell > 0, G^\ell \geq 0$ are explicitly given in terms of $\varphi^\ell$, the permittivity $\varepsilon$ and the electric conductivity $\sigma_e$ while $L^\ell > 0, R^\ell \geq 0$ are explicitly given in terms of $\psi^\ell$, the permeability $\mu$ and the magnetic conductivity $\sigma_m$. The system has to be completed by vertex conditions.

At first order, these are the Kirchoff’s laws

\[ V^\ell_0(0, t) - V^\ell_0(0, t) = 0, \quad \sum_{\ell=0}^L I^\ell_0(0, t) = 0. \] (4)

A better accuracy is obtained with second order conditions, namely improved Kirchoff laws

\[ V^\ell_0(0, t) - V^\ell_0(0, t) = \delta \sum_{\ell=1}^L Z^\ell \mathbf{I}^\ell_0(0, t), \]

\[ \sum_{\ell=1}^L I^\ell_0(0, t) + \delta Y \mathbf{V}^\ell_0(0, t) = 0, \]

(5)

where the coefficient $Y$ and the $L \times L$ matrix $Z = (Z_{\ell, \ell'})$ are defined from the material properties of the medium and from 3D potentials $\Phi$ and $\{ \Psi_\ell, 1 \leq \ell \leq L \}$ defined in the reference domain $\Omega^1$. These potentials are the solutions of elliptic equations in $\Omega^1$ that are constrained to satisfy a specific non homogeneous behavior at infinity inside each cable $\Omega^1$ (and, concerning the $\Psi_\ell$’s, non homogeneous jump conditions across $L$ artificial cuts).

Note that the condition (4) only sees the structure of the limit graph while (5) also takes into account (partly) the geometry of the junction.

3 The method of analysis

The derivation of (3) and (4) or (5) relies on a preliminary asymptotic expansion of the solution. Since the problem is of multi-scale nature, a uniform asymptotic expansion in the whole domain is not possible. We use the method of matched asymptotics, as in [2] for a simpler scalar case, which consists in looking for the electric field as follows:

- Far from the origin, for $x^3 > 0$, we use the ansatz

\[ E^\delta(x^1, x^3) = \sum_{p=0}^\infty \delta^p E_p^\delta \left( \frac{xt}{\delta}, x^3 \right) \]

where the fields $E_p^\delta$ are defined in $S^\ell \times \mathbb{R}^+$. 

- Close to the origin, we use the ansatz

\[ E^\delta(x) = \sum_{p=0}^\infty \delta^p E_p^\delta \left( \frac{x}{\delta} \right) \]

where the fields $E_p^\delta$ are defined in $\Omega^1$.

Our models are obtained only by looking at $p = 0, 1$. Using (6) leads to the construction of equation (3) (see [1]). To obtain (4) and (5), we need to express the fact that the two expansions (6) and (7) must match.

In addition, it is possible to obtain error estimates. More precisely, denoting $(E_{\text{app}}^\delta, H_{\text{app}}^\delta)$ the right hand side of (2) with $(V^\delta, I^\delta)$ defined as the solution of (3, 4) or (3, 5), one can show that, in appropriate energy norms

\[ \| E_{\text{app}}^\delta - E^\delta \| \leq C \delta^k \| E^\delta \| \]

where $k = 1$ for (3, 4) and $k = 2$ for (3, 5), modulo, in this second case, a post-treatment which consists in adding a $O(\delta)$ longitudinal component to the transverse electromagnetic field defines by the right hand side of (2).
