Abstract

An integer additive set-indexer is defined as an injective function $f : V(G) \rightarrow 2^{\mathbb{N}_0}$ such that the induced function $g_f : E(G) \rightarrow 2^{\mathbb{N}_0}$ defined by $g_f(uv) = f(u) + f(v)$ is also injective. An integer additive set-indexer is said to be k -uniform if $|g_f(e)| = k$ for all $e \in E(G)$. An integer additive set-indexer f is said to be a weak integer additive set-indexer if $|g_f(uv)| = \max(|f(u)|, |f(v)|)$ for all $u, v \in V(G)$. In this paper, we study the characteristics of certain graphs and graph classes which admit weak integer additive set-indexers.

Keywords: Integer additive set-indexers, weakly uniform integer additive set-indexers, weak integer additive set-indexers, mono-indexed elements of a graph, sparing number of a graph.

1 Introduction

For all terms and definitions, not defined specifically in this paper, we refer to [5]. Unless mentioned otherwise, all graphs considered here are simple, finite and have no isolated vertices.

The research in graph labeling problems commenced with the introduction of β -valuations in [7]. As a set analogue of number valuations of graphs, set-valuations are introduced in [1], as follows. Let G be a (p, q) -graph and let X, Y, Z be non-empty sets. Then the functions $f : V(G) \rightarrow 2^X$, $f : E(G) \rightarrow 2^Y$ and $f : V(G) \cup E(G) \rightarrow 2^Z$ are called the *set-assignments* of vertices, edges and elements of G respectively. By a set-assignment of a graph, we mean any one of them. A set-assignment is called a *set-labeling* or *set-valuation* if it is injective. A graph with a set-labeling f is denoted by (G, f) and is called a *set-labeled graph*.

For a (p, q) -graph $G = (V, E)$ and a non-empty set X of cardinality n , a *set-indexer* of G is defined in [1] as an injective set-valued function $f : V(G) \rightarrow 2^X$ such that the function $f^\oplus : E(G) \rightarrow 2^X - \{\emptyset\}$ defined by $f^\oplus(uv) = f(u) \oplus f(v)$ for every $uv \in E(G)$ is also injective, where 2^X is the set of all subsets of X and $\oplus$ is the symmetric difference of sets.

Theorem 1.1. [1] Every graph has a set-indexer.

Definition 1.1. Let $\mathbb{N}_0$ denote the set of all non-negative integers. For all $A, B \subseteq \mathbb{N}_0$, the sum of these sets is denoted by $A + B$ and is defined by $A + B = \{a + b : a \in A, b \in B\}$.

Definition 1.2. [3] An integer additive set-indexer (IASI, in short) is defined as an injective function $f : V(G) \rightarrow 2^{\mathbb{N}_0}$ such that the induced function $g_f : E(G) \rightarrow 2^{\mathbb{N}_0}$ defined by $g_f(uv) = f(u) + f(v)$ is also injective.

*Corresponding author. Email address: sudevkn@gmail.com, Tel: +919497557876.

Definition 1.3. [4] The cardinality of the labeling set of an element (vertex or edge) of a graph G is called the set-indexing number of that element.

Definition 1.4. [3] An IASI is said to be k -uniform if $|g_f(e)| = k$ for all $e \in E(G)$. That is, a connected graph G is said to have a k -uniform IASI if all of its edges have the same set-indexing number k . In particular, we say that a graph G has an arbitrarily k -uniform IASI if G has a k -uniform IASI for every positive integer k .

The characteristics of a special type of 1-uniform IASI graphs, called *sum square graphs*, have been studied in [3]. A characterisation of 2-uniform IASI graphs has been done in [2] and the following theorem was proved.

Theorem 1.2. [2] A graph G admits a 2-uniform IASI if and only if it is bipartite.

In the context of IASIs, in [4], we established the following lemma and introduced the notions following it.

Lemma 1.1. [4] Let A and B be two non-empty finite subsets of $\mathbb{N}_0$. Then, $\max(|A|, |B|) \leq |A+B| \leq |A| \cdot |B|$. Therefore, for an integer additive set-indexer f of a graph G , we have $\max(|f(u)|, |f(v)|) \leq |g_f(uv)| = |f(u) + f(v)| \leq |f(u)| \cdot |f(v)|$, where $u, v \in V(G)$.

Definition 1.5. [4] An IASI f is said to be a weak IASI if $|g_f(uv)| = \max(|f(u)|, |f(v)|)$ for all $u, v \in V(G)$.

We observe that at least one end vertex of each edge in a weak IASI graph has the set-indexing number 1.

Definition 1.6. [4] A weak IASI is said to be weakly uniform IASI if $|g_f(uv)| = k$, for all $u, v \in V(G)$ and for some positive integer k . A graph which admits a weak IASI may be called a weak IASI graph.

Theorem 1.3. [4] For $k > 1$, graph G admits a weakly k -uniform IASI if and only if it is bipartite. No non-bipartite graph G has a weakly k uniform IASI, for $k > 1$

Theorem 1.4. [4] A weakly k -uniform IASI graph is also an arbitrarily k -uniform IASI graph.

Theorem 1.5. [4] A graph G admits a k -uniform IASI if and only if k is odd or G is bipartite.

2 New Results on Weak IASI Graphs

In this paper, we establish more results on weak IASI graphs and graph operations. We proceed by defining the following notions.

Definition 2.1. An element (a vertex or an edge) of graph G , which has the set-indexing number 1, is called a mono-indexed element of that graph.

Definition 2.2. The sparing number of a graph G is defined to be the minimum number of mono-indexed edges required for G to admit a weak IASI. The sparing number of G is denoted by $\phi(G)$.

Theorem 2.1. If a graph G is a weak IASI graph, then any subgraph H of G is also a weak IASI graph.

Proof. Let G be a graph which admits a weak IASI and H be a subgraph of G . Let f^* be the restriction of f to $V(H)$. Then, g_{f^*} is the corresponding restriction of g_f to $E(H)$. Therefore, f^* is an induced set-indexer on H and is a weak IASI on H . Hence, H is a weak IASI graph. $\square$

Remark 2.1. As the contrapositive statement of Theorem 2.1, we notice that if a graph G does not admit weak IASI, then any supergraph of G does not have a weak IASI.

Now, we proceed to verify the existence of weak IASI for different classes of graphs.

Theorem 2.2. All bipartite graphs admit a weak IASI.

Proof. Let G be a bipartite graph with bipartition (V_1, V_2) of the vertex set $V(G)$. Assign distinct singleton sets to the vertices in V_1 and distinct non-singleton sets to the vertices in V_2 . This IASI is a weak IASI for G . $\square$

Remark 2.2. Due to Theorem 2.2, all paths, trees and even cycles admit a weak IASI. We also, observe that the sparing number of bipartite graphs is 0.

Theorem 2.3. If a connected graph G admits a weak IASI, then G is bipartite or G has at least one mono-indexed edge.

Proof. Assume that the graph G is a weak IASI graph. Then, by the definition of weak IASI, each edge of G has an end vertex which is mono-indexed. Let V_1 be the set of all mono-indexed vertices of G and $V_2 = V(G) - V_1$. If (V_1, V_2) forms a bipartition of $V(G)$, then the proof is complete. Hence, assume that (V_1, V_2) is not a bipartition of $V(G)$. Since every vertex of V_2 has the set-indexing number greater than 1, every edge connecting two vertices in V_2 , if exists, has both the end vertices with set-indexing number greater than 1, which is a contradiction to the hypothesis that G has a weak IASI. Hence, no two vertices of V_2 can be adjacent. Therefore, at least two vertices in V_1 must be adjacent. If e is such an edge in G , with both end vertices in V_1 , then the set-indexing number of e is 1. That is, G has at least one mono-indexed edge. $\square$

Theorem 2.4. Let G be a bipartite graph which admits a weak IASI and let u, v be two non-adjacent vertices in G . Then, $G + uv$ is a weak IASI graph if and only if $G + uv$ is bipartite or uv is a mono-indexed edge.

Proof. Let G be a bipartite graph which admits a weak IASI and let u, v be two non-adjacent vertices in G . Assume that $G_1 = G + uv$ be a weak IASI graph. Then by Theorem 2.3, G_1 is bipartite or the edge uv lies in the same partition of mono-indexed vertices in G . That is, if G_1 is non-bipartite, then uv is mono-indexed. Conversely, if $G_1 = G + uv$ is bipartite, then by Theorem 2.2, it has a weak IASI. If not, then by hypothesis, uv is mono-indexed. Since G is a weak IASI graph and uv is mono-indexed, $G + uv$ is a weak IASI graph. Hence, if $G + uv$ is bipartite or uv is mono-indexed, then $G + uv$ is a weak IASI graph. $\square$

Corollary 2.1. Let a complete bipartite graph $K_{m,n}$ be a weak IASI graph. Then, a graph $G = K_{m,n} + e$ admits a weak IASI if and only if e is a mono-indexed edge in G .

Proof. Since $K_{m,n}$ is complete bipartite, G can not be a bipartite graph. Then, by Corollary 2, e must be a mono-indexed edge of G . $\square$

Figure 1: illustrates a non-bipartite weak IASI graph with mono-indexed edges

Theorem 2.5. The complete graph K_n admits a weak IASI if and only if the minimum number of mono-indexed edges of K_n is $\frac{1}{2}(n-1)^2$. That is, the sparing number of a complete graph K_n is $\frac{1}{2}(n-1)^2$.

Proof. If K_n is 1-uniform, then the result is trivial. Hence, we consider the IASI graphs that are not 1-uniform. Assume that K_n admits a weak IASI. Then, every edge of K_n must have at least one end vertex of set-indexing number 1. Without loss of generality, label the vertex v_1 by a singleton set. Since v_2 is adjacent to v_1 , label v_2 by a non-singleton set. Since all other vertices $v_3, v_4, \dots, v_n$ are adjacent to v_2 in K_n and K_n admits a weak IASI, none of these vertices can be labeled by a non-singleton set. Therefore, only the edges incident on v_2 can have a set-indexing number greater than 1. That is, at most $(n-1)$ edges in K_n can have a set-indexing number greater than 1. Hence, the number of mono-indexed edges of K_n is $\frac{1}{2}n(n-1) - (n-1) = \frac{1}{2}(n-1)^2$.

Conversely assume that the number of mono-indexed edges of G is $\frac{1}{2}(n-1)^2$. Therefore, the number of edges in G having set-indexing number greater than 1 is $\frac{1}{2}n(n-1) - \frac{1}{2}(n-1)^2 = (n-1)$. Since K_n is an $(n-1)$ -regular graph, all these edges must incident on the same vertex, say v_i . That is, the vertex v_i is the only vertex that has the set-indexing number greater than 1. Clearly, this set-indexer is a weak IASI for K_n . $\square$

Figure 2: illustrates a complete graph which admits a weak IASI.

Since bipartite graphs support weak IASI, we now concentrate on non-bipartite graphs. First, we establish a necessary and sufficient condition for an odd cycle to have a weak IASI.

Theorem 2.6. *An odd cycle C_n has a weak IASI if and only if it has at least one mono-indexed edge.*

Proof. Let $C_n : v_0 v_1 v_2 \dots v_n$ be an odd cycle which admits a weak IASI. Then, $n = 2m + 1$ for some non-negative integer m . Without loss of generality, assign a singleton set to the vertex v_1 . Since C_n admits a weak IASI, the vertex v_2 adjacent to v_1 must be assigned by a non-singleton set. Let v_3 be the vertex which is adjacent to v_2 other than v_1 . Then, by definition of weak IASI, v_3 must be assigned by a singleton set other than the one assigned to v_1 . If v_4 is the vertex adjacent to v_3 , the vertex v_4 must be labeled by a non-singleton set, which has not already been used. Proceeding like this, we see that the vertices $v_1, v_3, v_5, \dots, v_{2m-1}$ have the set-indexing number 1 and $v_2, v_4, v_6, \dots, v_{2m}$ have set-indexing numbers greater than 1. Since C_n admits a weak IASI, the vertex v_{2m+1} should necessarily be labeled by a singleton set, which has not already been used. Therefore, the edge $v_{2m+1} v_1$ is mono-indexed.

Conversely, assume that $C_n : v_1 v_2, v_3, \dots, v_{n-1} v_n v_1$ be an odd cycle which can have a mono-indexed edge. Let $f : V(G) \rightarrow 2^{\mathbb{N}_0}$ be a labeling of vertices to distinct subsets of $\mathbb{N}_0$ defined as follows. Without loss of generality, label the vertices v_1 and v_n by distinct singleton sets. Hence, the edge $v_1 v_n$ is mono-indexed. Then, label the vertices v_2 and v_{n-1} by distinct non-singleton sets; label the vertices v_3 and v_{n-2} by distinct singleton sets that have not been already used; and label the vertices v_4 and v_{n-3} by distinct non-singleton sets, not already used before. Since C_n is an odd cycle, in the succeeding steps, the vertices that are adjacent to the preceding labeled vertices by distinct singleton sets and distinct non-singleton sets, (not already used before), we reach a single vertex v_r , where $r = \frac{1}{2}(n-1)$ and the vertices adjacent to whose end vertices are labeled by singleton sets (or non-singleton sets). Then, label the vertex v_r by a non-singleton set (or a singleton set in the latter case), that have not been already used. This set-indexer f is a weak IASI of C_n . $\square$

Invoking Remark 2.2 and Theorem 2.6, we have the following.

Remark 2.3. The sparing number of a cycle C_n is given by

$$f(v) = \begin{cases} 1 & \text{if } C_n \text{ is odd} \\ 0 & \text{if } C_n \text{ is even.} \end{cases}$$

An interesting question here is to know the number of mono-indexed edges in cycles. Following theorem answers this question.

Theorem 2.7. Let C_n be a cycle of length n which admits a weak IASI, for a positive integer n . Then, C_n has an odd number of mono-indexed edges when it is an odd cycle and has even number of mono-indexed edges, when it is an even cycle.

Proof. Let $C_n : v_1 v_2 v_3 \cdots v_n v_1$ be a cycle of length n which has a weak IASI.

Case 1: If n is even, then it can be considered as a bipartite graph with bipartition (X_1, X_2) in such a way that every vertex of X_1 is mono-indexed and every vertex of X_2 has the set-indexing number greater than 1. If we replace the labeling set of a vertex v in X_2 by a singleton set, then the set-indexing number of two edges incident on v becomes 1. Whenever we replace the non-singleton labeling set of a vertex by a singleton set, in X_2 , two edges attains the set-indexing number 1. Hence, C_n can only have even number of mono-indexed edges.

Case 2: If n is odd, then by Theorem 2.6, it has atleast one mono-indexed edge. If we replace a non-singleton labeling set of a vertex v in C_n by a singleton set, then two edges incident on v attains a set-indexing number 1. Whenever we replace a non-singleton labeling set of any vertex of C_n by a singleton set, the number of edges having set-indexing number is increased by 2. Therefore, C_n has odd number of mono-indexed edges. $\square$

Definition 2.3. [6] Let G be a connected graph and let v be a vertex of G with $d(v) = 2$. Then, v is adjacent to two vertices u and w in G . If u and w are non-adjacent vertices in G , then delete v from G and add the edge uw to $G - \{v\}$. This operation is known as an *elementary topological reduction* on G .

Theorem 2.8. Let C_n be a cycle which admits a weak IASI. Then, any graph H , obtained by applying finite number of elementary topological reduction on C_n , admits a weak IASI.

Proof. We prove the theorem in three steps.

Step-1: If C_n has no mono-indexed edge, then proceed to Step 2. If C_n consists of mono-indexed edges, then delete one end vertex v of a mono-indexed edge. Then, two edges will be deleted and $C_n - v$ has two pendant vertices, of which, one vertex has the set-indexing number 1 and the other vertex has a set-indexing number 1 or greater than 1. Join these vertices by an edge. The resultant graph is a cycle, which also has a weak IASI. Repeat this process until all edges having set-indexing number 1 have been deleted.

Step-2: At this stage, we have a cycle $C_j, j < i$ which contains no mono-indexed edges. The cycle C_j also admits a weak IASI. Now, delete a vertex v that is not mono-indexed and the two edges incident on it. Hence, $C_j - v$ has two pendant vertices each of which has the set-indexing number 1. Repeat this steps until all possible such vertices are deleted.

Step-3: Repeat Step-1 and Step-2 successively until we get a cycle C_3 of length 3, all of whose vertices are mono-indexed (or two vertices are mono-indexed and one vertex has set-indexing number greater than 1). Hence C_3 also admits a weak IASI. $\square$

Figure 3: illustrates the existence of weak IASI for the graphs H_1 and H_2 obtained by applying a finite number of elementary topological reduction on the cycle C_5 .

By *edge contraction operation* in G , we mean an edge, say e , is removed and its two incident vertices, u and v , are merged into a new vertex w , where the edges incident to w each correspond to an edge incident to either u or v . We establish the following theorem for the graphs obtained by contracting the edges of a given graph G .

Theorem 2.9. *Let G be a weak IASI graph and let G' be the graph obtained by contracting an edge e of G . G' admits a weak IASI if and only if G' is bipartite or e is a mono-indexed edge.*

Proof. Let G be a weak IASI graph and let G' be a graph obtained from G by deleting an edge e of G and identifying the end vertices of e . Label the new vertex by the set-label of the deleted edge. If e is a mono-indexed edge, then deleting e and identifying its end vertices will result in a new vertex w , labeled with set-labeling of e , which is mono-indexed. Then G' is a weak IASI graph.

Conversely, assume that G' is a weak IASI graph. If G' is bipartite, then proof is complete. Hence, assume that G' is not bipartite. Let $e = uv$ an edge in G such that $G' = G \circ e$. Now, remove e from G and identify the vertices u and v to a new vertex w . Label the vertex w by the labeling set of uv . We have to show that both u and v are mono-indexed. Assume the contrary. Since G admits a weak IASI, u and v simultaneously can not have a set-indexing number greater than 1. Hence, without loss of generality, let u be mono-indexed and v be not mono-indexed. Since $G \circ e$ is non-bipartite, u must be adjacent to at least one vertex, say x , which is not mono-indexed. Therefore, in $G \circ e$, the edge xw has both end vertices which are not mono-indexed, which is a contradiction. Therefore, both u and v must be mono-indexed. Hence, e is mono-indexed. $\square$

Figure 4: illustrates the admissibility of weak IASI by a graph obtained from contracting a mono-indexed edge in a weak IASI graph G .

3 Conclusion

In this paper, we have given some characteristics of the graphs which admit weak IASIs. We have identified some problems related to weak IASI graphs which demands further investigation. They are

Problem 3.1. *Examine the admissibility of weak IASI by certain graph operations and determine their sparing number.*

Problem 3.2. *Examine the admissibility weak IASI by the Cartesian product of two weak IASI graphs and the corresponding sparing number.*

Problem 3.3. *Determine the necessary and sufficient conditions for the given general (non-bipartite) graphs to admit weak IASIs and determine corresponding sparing numbers.*

One may establish more properties and characteristics of weak IASI graphs, both uniform and non-uniform. More studies may be done in the field of IASI when the ground set X is finite instead of $\mathbb{N}_0$. We have formulated some conditions for certain graph classes to admit weak IASI. The problems of establishing the necessary and sufficient conditions for various graphs and graph classes to have certain IASIs still remain unsettled. All these facts highlight a great scope for further studies in this area.

In the recently published article titled *A Characterisation of Weak Integer Additive Set-Indexers of Graphs* (article id:jfsva-00189) an inadvertent error in the final simplification has been occurred. Theorem 2.5 is stated in the article as

“The complete graph K_n admits a weak IASI if and only if the minimum number of mono-indexed edges of K_n is $\frac{1}{2}(n-1)^2$. That is, the sparing number of a complete graph K_n is $\frac{1}{2}(n-1)^2$ ”.

The same expression is written in the proof of Theorem 2.5 in Page 4 (lines 7, 8, 9). The correct expression in all the above lines is $\frac{1}{2}(n-1)(n-2)$ instead of $\frac{1}{2}(n-1)^2$.

Hence, the corrected statement and proof of Theorem 2.5 is

Theorem 2.5 *“The complete graph K_n admits a weak IASI if and only if the minimum number of mono-indexed edges of K_n is $\frac{1}{2}(n-1)(n-2)$. That is, the sparing number of a complete graph K_n is $\frac{1}{2}(n-1)(n-2)$ ”.*

Proof. If K_n is 1-uniform, then the result is trivial. Hence, we consider the IASI graphs that are not 1-uniform.

Assume that K_n admits a weak IASI. Then, every edge of K_n must have at least one end vertex of set-indexing number 1. Without loss of generality, label the vertex v_1 by a singleton set. Since v_2 is adjacent to v_1 , label v_2 by a non-singleton set. Since all other vertices $v_3, v_4, \dots, v_n$ are adjacent to v_2 in K_n and K_n admits a weak IASI, none of these vertices can be labeled by a non-singleton set. Therefore, only the edges incident on v_2 can have a set-indexing number greater than 1. That is, only $(n-1)$ edges in K_n have a set indexing number greater than 1. Hence, the number of mono-indexed edges of K_n is $\frac{1}{2}n(n-1) - (n-1) = \frac{1}{2}(n-1)(n-2)$.

Conversely, assume that the number mono-indexed edges of G is $\frac{1}{2}(n-1)(n-2)$. Therefore, the number edges of G having set-indexing numbers greater than 1 is $\frac{1}{2}n(n-1) - \frac{1}{2}(n-1)(n-2) = (n-1)$. Since K_n is an $(n-1)$ -regular graph, all these edges must incident on the same vertex, say v_i . That is, the vertex v_i is the only vertex that has a set-indexing number greater than 1. This set-indexer is a weak IASI for K_n .
