Abstract

We consider in this paper a model parabolic variational inequality. This problem is discretized with conforming Lagrange finite elements of order \( p \geq 1 \) in space and with the backward Euler scheme in time. The nonlinearity coming from the complementarity constraints is treated with any semismooth Newton algorithm and we take into account in our analysis an arbitrary iterative algebraic solver. In the case \( p = 1 \), when the system of nonlinear algebraic equations is solved exactly, we derive an a posteriori error estimate on both the energy error norm and a norm approximating the time derivative error. When \( p \geq 1 \), we provide a fully computable and guaranteed a posteriori estimate in the energy error norm which is valid at each step of the linearization and algebraic solvers. Our estimate, based on equilibrated flux reconstructions, also distinguishes the discretization, linearization, and algebraic error components.

We build an adaptive inexact semismooth Newton algorithm based on stopping the iterations of both solvers when the estimators of the corresponding error components do not affect significantly the overall estimate. Numerical experiments are performed with the semismooth Newton-min algorithm and the semismooth Newton–Fischer–Burmeister algorithm in combination with the GMRES iterative algebraic solver to illustrate the strengths of our approach.

Keywords: parabolic variational inequality, complementarity condition, semismooth Newton method, algebraic solver, a posteriori error estimate, adaptivity, stopping criterion

1 Introduction

Let \( \Omega \subset \mathbb{R}^2 \) be a polygonal domain and let \( T > 0 \) denote the final time. Let \( H^1(\Omega) \) be the space of \( L^2 \) functions on the domain \( \Omega \) which admit a weak gradient in \( [L^2(\Omega)]^2 \) and \( H^1_0(\Omega) \) its zero-trace subspace. Consider the affine space \( H^1_g(\Omega) := \{ v \in H^1(\Omega), v = g \text{ on } \partial \Omega \} \), where \( g \) is a positive constant and denote the dual space of \( H^1_0(\Omega) \) by \( H^{-1}(\Omega) \), with the duality pairing \( \langle \cdot, \cdot \rangle \).

Consider a bilinear continuous form \( a(\cdot, \cdot) : [H^1(\Omega)]^2 \times [H^1(\Omega)]^2 \to \mathbb{R} \), coercive on \( [H^1_0(\Omega)]^2 \). Let \( K_g \) be a nonempty closed convex subset of \( H^1_g(\Omega) \times H^1_0(\Omega) \) and let \( K_t \) be its evolutive-in-time version

\[
K_t := \{ v \in L^2(0, T; H^1_g(\Omega)) \times L^2(0, T; H^1_0(\Omega)), \text{ } v(t) \in K_g \text{ a.e. in } [0, T]\}.
\]

We consider the following parabolic variational inequality: for the data \( f := (f_1, f_2) \in [L^2(0, T; L^2(\Omega))]^2 \) and the initial condition \( u^0 = (u_1^0, u_2^0) \in K_g \), find \( u = (u_1, u_2) \in K_t \) such that \( \partial_t u \in [L^2(0, T; H^{-1}(\Omega))]^2 \)
and such that for all $v \in \mathcal{K}_g^t$

$$
\int_0^T \langle \partial_t u, v - u \rangle(t) \, dt + \int_0^T a(u, v - u)(t) \, dt \geq \int_0^T (f, v - u)_\Omega(t) \, dt,
$$

(1.2)

Problem (1.2) belongs to the wide class of parabolic variational inequalities of the first kind, see Glowinski [1] and Lions [2] for a general introduction. Evolutionary variational inequalities have attracted recent interest in a wide variety of applications. We mention the problems in modeling pricing of American options [3, 4], the applications in stochastic control [5], and obstacle problems in mechanics [2, 6, 7, 8]. Existence and uniqueness of a weak solution for (1.2) is classical, see [2, 9, 10] and the references therein.

For spatial discretization of variational inequalities, the finite element method is commonly employed, see Chen and Nochetto [11], Veeser [12], Braess [13], or Ben Belgacem et al. [14] for a $P_1$ conforming solution, and Bürg and Schröder [15], Dabaghi et al. [16] for a $P_p$ nonconforming solution. Discontinuous Galerkin methods have been studied in Wang et al. [17] and Gudi and Porwal [18, 19, 20], finite volumes in Herbin and Marchand [21], Berton and Eymard [22], and Steinbach [23], and discontinuous skeletal methods in the recent work of Cicuttin, Ern, and Gudi [24]. The discretization in time often uses the backward Euler scheme.

Among the spectrum of methods for the solution of the systems of algebraic inequalities arising from discretizations of (1.2), let us mention the interior point method of Wright [25], the active set strategy by Kanzow [26], the primal-dual active set strategy by Hintermüller [27], the family of the semismooth Newton methods (see [28, 29, 30, 31]). In this work, we use a saddle-point Lagrangian formulation giving rise at each time step $n$ to a nonlinear system of algebraic equations of the form

$$
S^n(X^n_h) = 0,
$$

(1.3)

where $S$ is a nonlinear operator and $X^n_h \in \mathbb{R}^m$, $m \geq 1$, is the unknown vector of degrees of freedom. We employ any semismooth linearization procedure starting from an initial guess $X^{0,0}_h \in \mathbb{R}^m$ and giving at each step $k \geq 1$ the system of linear algebraic equations

$$
\mathbb{A}^{n,k-1}X^{n,k}_h = F^{n,k-1},
$$

(1.4)

where the matrix $\mathbb{A}^{n,k-1} \in \mathbb{R}^{m,m}$ and the vector $F^{n,k-1} \in \mathbb{R}^m$ are constructed from $X^{n,k-1}_h \in \mathbb{R}^m$. Solving (1.4) with a direct method may be very expensive. A popular approach is to employ an inexact algebraic solver giving at each iterative linear algebraic step $i \geq 0$ and each linearization step $k \geq 1$ a residual vector $R^{n,k,i}_h \in \mathbb{R}^m$ defined by

$$
R^{n,k,i}_h := F^{n,k-1} - \mathbb{A}^{n,k-1}X^{n,k-1}_h.
$$

(1.5)

In the present work, we focus on answering the following questions: To which precision should (1.4) be solved? To which precision should (1.3) be resolved? Can we estimate the total error, as well as each error component (discretization, linearization, algebraic) of the overall numerical approximation? Can we reduce the typical number of iterations of both linearization and algebraic solvers?

Our key tool to propose answers to the above questions is the a posteriori error analysis. A huge amount of work has been performed in the recent past on a posteriori error estimates for partial differential equations. We can mention the pioneering work of Prager and Synge [32], Babuška and Rheinboldt [33], Ainsworth and Oden [34], and Verfürth [35] for a general introduction. For elliptic variational inequalities, we can mention the contributions [36, 37, 38, 15, 11, 12, 13, 18, 20, 39]. In contrast to the last references, in Bürg and Schröder [15] and Dabaghi et al. [16], a $P_p$ conforming finite element discretization, yielding a nonconforming approximation of variational inequalities for $p \geq 2$ are employed. In [16], three components of the error are distinguished: the discretization error, the semismooth linearization error, and the iterative algebraic error.

In the context of parabolic problems, a posteriori analysis has received significant attention over the past decade. For parabolic equations, we mention Verfürth [40], Bernardi, Bergham, and Mghazli [41], and Ern, Smears, and Vohralík [42, 43], where in particular in [42], local efficiency in space and in time for the estimators is proven. For parabolic variational inequalities, the edifice seems still under construction.
can mention Moon, Nochetto, Petersdorff, and Zhang [44] for a study of the Black–Scholes model, Achdou, Hecht, and Pommier [7] for a study of the parabolic obstacle problem, and Gimperlein and Stoccek [45] for a large variety of parabolic variational inequalities. In the present work, we follow the methodology of [42] and [16] to derive a posteriori error estimates for a parabolic variational inequality with distinction of each component of the error. In particular, this enables us to define adaptive stopping criteria for nonlinear semismooth and linear algebraic solvers, which is new to the best of our knowledge. Importantly, it enables to save many unnecessary iterations.

To exemplify our approach, we consider the system of unsteady parabolic variational inequalities as an extension of the stationary model problem studied in [16]. Two important difficulties arise for the a posteriori analysis in this setting:

1) Denoting by \( \mathbf{u}_{h_T}^{k,i} := \left( u_{1h_T}^{k,i}, u_{2h_T}^{k,i} \right) \) the space-time numerical approximation, where the indices \( k, i \) indicate the presence of inexact linearization and algebraic solvers and where \( u_{h_T}^{k,i} \) is piecewise affine and continuous in time and piecewise polynomial of degree \( p \) and continuous for each variable in space, \( u_{h_T}^{k,i} \) is nonconforming in the sense that \( u_{h_T}^{k,i} \notin \mathcal{K}_h^1 \). Denoting by \( \lambda_{h_T}^{k,i} \) the discrete counterpart of the Lagrange multiplier \( \lambda \), the same phenomenon occurs in the sense that \( \lambda_{h_T}^{k,i} \) is not also conforming. 2) We cannot easily provide, as for the parabolic heat equation, an a posteriori upper bound for the time derivative \( \| \partial_t \left( u - u_{h_T}^{k,i} \right) \|_{[L^2(0,T;H^{-1}(\Omega))]^2} \). To tackle this difficulty at least for \( p = 1 \) and exact solvers, where we simply denote \( \mathbf{u}_{h_T} = \mathbf{u}_{h_T}^{k,i} \), we construct an element \( \mathbf{z} \in \mathcal{K}_g \) such that \( \| u - \mathbf{z} \|_{[L^2(0,T;H^1_0(\Omega))]^2} \) is closely linked to \( \| \partial_t \left( u - \mathbf{u}_{h_T} \right) \|_{[L^2(0,T;H^{-1}(\Omega))]^2} \) and such that the a posteriori error estimate holds as

\[
\| u - \mathbf{u}_{h_T} \|^2_{[L^2(0,T;H^1_0(\Omega))]^2} + \| u - \mathbf{z} \|^2_{[L^2(0,T;H^1_0(\Omega))]^2} + \| (u - \mathbf{u}_{h_T}) ;(\cdot,T) \|^2_{L^2(\Omega)} \leq (\eta(\mathbf{u}_{h_T}))^2 ,
\]

with \( \eta(\mathbf{u}_{h_T}) \) depending only on the approximate solution \( \mathbf{u}_{h_T} \).

This contribution is structured as follows. We first present the model problem, its weak formulation, and its discretization with the backward Euler scheme in time and the conforming \( P_p \) \((p \geq 1)\) finite element method in space. In particular, we show that our nonlinear system may be seen as a system of parabolic partial differential equations with complementarity constraints. Then, we present the concept of inexact semismooth Newton methods to solve our system of algebraic inequalities at each time step. Next, we provide a posteriori analysis following the approach of the equilibrated flux reconstructions. In particular, we derive an a posteriori error estimate for affine finite elements (p = 1) at each time step \( n \) when the semismooth Newton solver as well as the algebraic iterative solver have converged. Then we can estimate the error as shown in (1.6). We next provide a second a posteriori error estimate, valid for any \( p \geq 1 \) at each semismooth linearization iteration \( k \geq 1 \) and at each iterative algebraic solver iteration \( i \geq 0 \). This estimate only bounds the first component on the left-hand side of (1.6), but distinguishes the different error components, namely the discretization error, the semismooth linearization error, the algebraic error, and the initial error, taking the form

\[
\| u - u_{h_T}^{k,i} \|^2_{[L^2(0,T;H^1_0(\Omega))]^2} \leq \eta(u_{h_T}^{k,i}) \leq \eta_{\text{disc}}^{k,i} + \eta_{\text{lin}}^{k,i} + \eta_{\text{alg}}^{k,i} + \eta_{\text{init}}^{k,i}.
\]

This lead us to a proposition of an adaptive inexact semismooth Newton algorithm for parabolic problems. Finally, we present numerical experiments when \( p = 1 \) with the Newton-min algorithm as well as with the Newton–Fischer–Burmeister algorithm in combination with the GMRES algebraic solver, assessing the strengths of our approach.
Model problem and setting

Let $\Omega \subset \mathbb{R}^2$ be a polygonal domain and $T > 0$ be the final simulation time. The model problem we consider here is to find $u_1$, $u_2$, and $\lambda$ such that

$$
\begin{aligned}
\partial_t u_1 - \mu_1 \Delta u_1 - \lambda &= f_1 & \text{in} & & \Omega \times [0, T] \\
\partial_t u_2 - \mu_2 \Delta u_2 + \lambda &= f_2 & \text{in} & & \Omega \times [0, T] \\
(u_1 - u_2)\lambda &= 0, & u_1 - u_2 &\geq 0, & \lambda \geq 0 & \text{in} & & \Omega \times [0, T] \\
u_1 &= g & \text{on} & & \partial \Omega \times [0, T] \\
u_2 &= 0 & \text{on} & & \partial \Omega \times [0, T] \\
u_1(0) = u_1^0, & u_2(0) = u_2^0, & u_1^0 - u_2^0 &\geq 0 & \text{in} & & \Omega
\end{aligned}
$$

(2.1)

Here, the real coefficients $\mu_1$ and $\mu_2$ are supposed constant and strictly positive, and, for the sake of simplicity, we assume that the Dirichlet boundary condition $g > 0$ is also a constant. The source term $f := (f_1, f_2)$ is supposed to belong to $[L^2(0, T; L^2(\Omega))]^2$. Finally, the initial conditions are supposed to satisfy $u^0 := (u_1^0, u_2^0) \in H^1_0(\Omega) \times H^1_0(\Omega)$ and $u_1^0 - u_2^0 \geq 0$ a.e. in $\Omega$. The two first equations of (2.1) are of parabolic type. The third line of (2.1) states linear complementarity conditions expressing that either $u_1 - u_2 = 0$ and $\lambda > 0$, or $u_1 - u_2 > 0$ and $\lambda = 0$. Observe that when $u_1 - u_2 > 0$ and $\lambda = 0$ everywhere in $\Omega \times [0, T]$, problem (2.1) is equivalent to solving two separated heat equations. On the other hand, when $f_1$ and $f_2$ are independent of time and $\partial_t u_1 = \partial_t u_2 = 0$, (2.1) becomes the stationary contact problem between two membranes studied in [14, 46, 17, 16].

We define the sets

$$
\Lambda := \{\chi \in L^2(\Omega), \ \chi \geq 0 \text{ a.e. in } \Omega\} \quad \text{and} \quad \Psi := L^2(0, T; \Lambda).
$$

We also introduce the nonempty closed convex set

$$
\mathcal{K}_g := \{(v_1, v_2) \in H^1_0(\Omega) \times H^1_0(\Omega), \ v_1 - v_2 \geq 0 \text{ a.e. in } \Omega\},
$$

(2.2)

as well as its evolutive-in-time version $\mathcal{K}_g^\alpha$ defined by (1.1). Note that since $(g, 0) \in L^2(0, T; H^1_0(\Omega)) \times L^2(0, T; H^1_0(\Omega))$, $\mathcal{K}_g^\alpha$ is nonempty. The compact notations

$$
a(u, v) := \sum_{\alpha=1}^2 \mu_\alpha (\nabla u_\alpha, \nabla v_\alpha)_\Omega, \quad b(v, \chi) := (\chi, v_1 - v_2)_\Omega
$$

(2.3)

will be useful henceforth, where $u = (u_1, u_2)$, $v = (v_1, v_2)$, $a$ is continuous and coercive as described in the introduction, and $b$ is a continuous bilinear form on $[H^1(\Omega)]^2 \times L^2(\Omega)$.

The weak formulation of problem (2.1) is given by the parabolic variational inequality (1.2) and it is well-posed. To illustrate the construction of the numerical discretization in Section 3 below, let us also mention that alternatively, one could look for $(u_1, u_2, \lambda) \in L^2(0, T; H^1_0(\Omega)) \times L^2(0, T; H^1_0(\Omega)) \times \Psi$ such that $\partial_t u_\alpha \in L^2(0, T; H^{-1}(\Omega)), \ \alpha = 1, 2$, and satisfying for almost all $t \in [0, T]$ and for all $(v_1, v_2, \chi) \in H^1_0(\Omega) \times H^1_0(\Omega) \times \Lambda$

$$
\begin{aligned}
\sum_{\alpha=1}^2 (\partial_t u_\alpha(t), v_\alpha) + \sum_{\alpha=1}^2 \mu_\alpha (\nabla u_\alpha(t), \nabla v_\alpha)_\Omega &- (\lambda(t), v_1 - v_2)_\Omega = \sum_{\alpha=1}^2 (f_\alpha(t), v_\alpha)_\Omega, \\
(\chi - \lambda(t), u_1(t) - u_2(t))_{\Omega} &\geq 0, \\
u(0) &= u^0.
\end{aligned}
$$

(2.4)

The second line in (2.4) can also be interpreted as a linear complementarity constraint, cf. a derivation in the case of a stationary problem in [47, 16], reading as

$$
(u_1 - u_2)(t) \geq 0, \quad \lambda(t) \geq 0, \quad \lambda(t)(u_1 - u_2)(t) = 0.
$$

(2.5)

Finally, standard notations $\nabla$ and $\nabla \cdot$ are used respectively for the weak gradient and divergence operators. For a nonempty set $O$ of $\mathbb{R}^2$, we denote its Lebesgue measure by $|O|$ and the $L^2(O)$ scalar product for
polynomial and continuous functions

also denote by $a$ vertex

for $w = (w_1, w_2) \in [L^2(\Omega)]^2$, and $\|\nabla v\|_\Omega^2 := (\nabla v, \nabla v)_\Omega$. Then, we define the space energy norm:

$$\forall v = (v_1, v_2) \in [H_0^1(\Omega)]^2, \quad \|v\|_\Omega := \left\{ \sum_{n=1}^{2} \mu_n \|\nabla v_n\|_\Omega^2 \right\}^{\frac{1}{2}}.$$  

(2.6)

For a function $v = (v_1, v_2) \in [L^2(0, T; H_0^1(\Omega))]^2$, we then define the space-time energy norm by

$$\|v\|_{\Omega, T} := \left\{ \int_0^T \|v(t)\|_\Omega^2 \right\}^{\frac{1}{2}}.$$  

(2.7)

3 Discretization and semismooth Newton linearization

The discretization relies on the backward Euler scheme in time and on the conforming finite element method of degree $p \geq 1$ in space.

3.1 Setting

For the time discretization, we introduce a division of the interval $[0, T]$ into subintervals $I_n := [t_{n-1}, t_n]$, $1 \leq n \leq N_\varepsilon$, such that $0 = t_0 < t_1 < \cdots < t_{N_\varepsilon} = T$. The time steps are denoted by $\Delta t_n = t_n - t_{n-1}$, $n = 1, \cdots, N_\varepsilon$. For the space discretization, we consider a conforming simplicial mesh $\mathcal{T}_h$ of the domain $\Omega$, i.e., $\mathcal{T}_h$ is a set of triangles $K$ verifying

$$\bigcup_{K \in \mathcal{T}_h} K = \Omega,$$

where the intersection of the closure of two elements of $\mathcal{T}_h$ is either an empty set, a vertex, or an edge. The set of vertices of $\mathcal{T}_h$ is denoted by $\mathcal{V}_h$ and is partitioned into interior vertices $\mathcal{V}_h^{int}$ and boundary vertices $\mathcal{V}_h^{ext}$. We denote by $\mathcal{N}_h^{int}$ the number of interior vertices. The vertices of an element $K \in \mathcal{T}_h$ are collected in the set $\mathcal{V}_K$. Denote by $h_K$ the diameter of a triangle $K$ and $h := \max_{K \in \mathcal{T}_h} h_K$. Furthermore, for the vertex $a \in \mathcal{V}_h$, let the patch $\omega_h^a \subset \Omega$ be the domain made up of the elements of $\mathcal{T}_h$ that share $a$. The vector $\mathbf{n}_h^a$ stands for its outward unit normal. In the sequel, we use the discrete conforming space of piecewise polynomial and continuous functions

$$X^p_h := \{ v_h \in C^0(\Omega); v_h|_K \in \mathbb{P}_p(K), \forall K \in \mathcal{T}_h \} \subset H^1(\Omega),$$

where $\mathbb{P}_p(K)$ stands for the set of polynomials of total degree less than or equal to $p$ on the element $K$. We also denote by $\mathcal{V}_h^d$ the set of the Lagrange nodes of the space $X^p_h$ and by $\mathcal{N}_h^d$ its cardinality. The internal degrees of freedom are collected in the set $\mathcal{V}_h^{int}$ whose cardinality is $\mathcal{N}_h^{int}$, and the boundary ones are collected in the set $\mathcal{V}_h^{ext}$. The Lagrange basis functions of $X^p_h$ are denoted by $(\psi_{h, x_1})_{1 \leq l \leq \mathcal{N}_h^d}$ for $x_l \in \mathcal{V}_h^d$. We recall that $\psi_{h, x_1}(x_l) = 1$ for all $x_l \in \mathcal{V}_h^d$ and $\psi_{h,x_1}(x_l) = 0$ for all $(x_2)_{1 \leq l \leq \mathcal{N}_h^d} \in \mathcal{V}_h^d$. In the particular case $p = 1$, the set $\mathcal{V}_h^1$ coincides with $\mathcal{V}_h$ and the Lagrange basis functions are the “hat” basis functions that are denoted by $\psi_{h, a}, a \in \mathcal{V}_h$. Still in this case, we denote $M_a := (\psi_{h,a}, 1)\omega_h^a = \frac{\omega_h^a}{4}$. We also introduce the boundary-aware set and space

$$X^p_{gh} := \{ v_h \in X^p_h; \ v_h|_{\partial\Omega} = g \} \subset H^1_0(\Omega), \quad X^p_{0h} := X^p_h \cap H^1_0(\Omega),$$

and the convex set

$$\mathcal{K}^p_{gh} := \left\{ (v_{1h}, v_{2h}) \in X^p_{gh} \times X^p_{0h}, \ v_{1h}(x_l) - v_{2h}(x_l) \geq 0 \ \forall (x_l)_{1 \leq l \leq \mathcal{N}_h^d} \in \mathcal{V}_h^d \right\}.$$  

(3.1)

Recall the definition (2.2) and observe that $\mathcal{K}_{gh}^1 \subset \mathcal{K}_g$ holds in the case $p = 1$ but $\mathcal{K}^p_{gh} \not\subset \mathcal{K}_g$ for $p \geq 2$, see [11, 12, 14, 16]. For $\alpha = 1, 2$, let us introduce the piecewise constant in time functions $f_\alpha \in L^2(0, T; L^2(\Omega))$ such that

$$(f_\alpha)|_{t_n} := \frac{1}{\Delta t_n} \int_{t_n} f_{\alpha}(t) \, dt, \quad \text{and denote } \tilde{f}_\alpha := (f_\alpha)|_{t_n} \in L^2(\Omega), \tilde{f} := (\tilde{f}_1, \tilde{f}_2), \tilde{f}^a := (\tilde{f}_1^a, \tilde{f}_2^a).$$  

(3.2)
3.2 Discrete reduced problem and discrete saddle-point problem

Let
\[ c_n(u_h^n, v_h) := \frac{1}{\Delta t_n} \sum_{a=1}^2 (u_{ah}^n, v_{ah})_\Omega, \quad 1 \leq n \leq N_t. \]

Given \( u_h^n \in K_{gh}^p \), the discrete reduced problem corresponding to (1.2) consists in searching for all \( 1 \leq n \leq N_t \) \( u_h^n \in K_{gh}^p \) such that for all \( v_h \in K_{gh}^p \)
\[ c_n (u_h^n - u_h^{n-1}, v_h - u_h^n) + a(u_h^n, v_h - u_h^n) \geq (\tilde{f}_n, v_h - u_h^n)_\Omega. \] (3.3)

Following the Lions–Stampacchia theorem [48], we have:

Proposition 1. The discrete problem (3.3) admits a unique solution.

Recall that when \( p \geq 2 \), \( u_h^n \) is typically nonconforming in the sense that \( u_h^n \notin K_{gh} \). Moreover, following the methodology of [16, 14, 18, 15], knowing \( u_h^n \), the solution to (3.3), we define for \( 1 \leq n \leq N_t \) and for all \( \alpha = 1, 2 \) the functions \( \lambda_{\alpha h}^n \in X_h^p \) by
\[ (\lambda_{\alpha h}^n, z_{ah})_h := (-1)\alpha \left[ -\frac{1}{\Delta t_n} (u_{ah}^n - u_{ah}^{n-1}, z_{ah})_\Omega + \mu_\alpha (\nabla u_{ah}^n, \nabla z_{ah})_\Omega + \left( \tilde{f}_n^\alpha, z_{ah} \right)_\Omega \right] \forall z_{ah} \in X_{gh}^p, \] (3.4)
where for all \( (w_h, v_h) \in X_h^p \times X_h^p \),
\[ \langle w_h, v_h \rangle_h := \sum_{a \in Y_h} w_h(a) v_h(a) M_a \quad \text{if} \quad p = 1, \quad \text{and} \quad \langle w_h, v_h \rangle_h := (w_h, v_h)_\Omega \quad \text{if} \quad p \geq 2. \]

Lemma 3.1. Let \( 1 \leq n \leq N_t \) be a time step and \( (u_{1h}^n, u_{2h}^n) \in K_{gh}^p \) be the solution of the reduced discrete problem (3.3). Then, the functions \( \lambda_{1h}^n \) and \( \lambda_{2h}^n \) defined by (3.4) coincide.

Proof. From (3.4) and taking \( z_{1h} = z_{2h} = \psi_{h, x_l} \) with \( x_l \) any internal Lagrange node, we get
\[ (\lambda_{1h}^n - \lambda_{2h}^n, \psi_{h, x_l})_h = \frac{1}{\Delta t_n} \sum_{a=1}^2 \left[ (u_{ah}^n - u_{ah}^{n-1}, \psi_{h, x_l})_\Omega + \mu_\alpha (\nabla u_{ah}^n, \nabla \psi_{h, x_l})_\Omega \right] - \left( \tilde{f}_1^n + \tilde{f}_2^n, \psi_{h, x_l} \right)_\Omega. \]

Taking \( v_{1h} := u_{1h}^n + \psi_{h, x_l} \) and \( v_{2h} := u_{2h}^n + \psi_{h, x_l} \) so that \( (v_{1h}, v_{2h}) \in K_{gh}^p \), we see
\[ (\lambda_{1h}^n - \lambda_{2h}^n, \psi_{h, x_l})_h \geq 0 \quad \forall l = 1 \ldots N_d^{p, \text{int}}. \] (3.5)

In the same way, taking \( v_{1h} := u_{1h}^n - \psi_{h, x_l} \) and \( v_{2h} := u_{2h}^n - \psi_{h, x_l} \), we have \( (v_{1h}, v_{2h}) \in K_{gh}^p \) and we get
\[ (\lambda_{1h}^n - \lambda_{2h}^n, \psi_{h, x_l})_h \leq 0 \quad \forall l = 1 \ldots N_d^{p, \text{int}}. \] (3.6)

The conclusion follows the last lines of [16, Lemma 2.1].

Following Lemma 3.1, we can set \( \lambda_h^n := \lambda_h^n = \lambda_h^n \in X_h^p \). Moreover, \( \lambda_h^n \) satisfies the following property:

Lemma 3.2. Let \( 1 \leq n \leq N_t \), let \( (u_{1h}^n, u_{2h}^n) \in K_{gh}^p \) be the solution of the reduced discrete problem (3.3), and let \( \lambda_h^n \) be defined by (3.4). Then, there holds
\[ (\lambda_h^n, \psi_{h, x_l})_h \geq 0 \quad \forall x_l \in Y_d^{p, \text{int}}. \]

Proof. For \( x_l \in Y_d^{p, \text{int}} \), observe that \( (v_{1h}, v_{2h}) := (u_{1h}^n + \psi_{h, x_l}, u_{2h}^n) \in K_{gh}^p \). Using the reduced problem (3.3), the characterization (3.4) with \( z_{1h} = \psi_{h, x_l} \in X_{gh}^p \), and Lemma 3.1, we get for all \( l = 1 \ldots N_d^{p, \text{int}} \)
\[ \frac{1}{\Delta t_n} (u_{1h}^n - u_{1h}^{n-1}, \psi_{h, x_l})_\Omega + \mu_1 (\nabla u_{1h}^n, \nabla \psi_{h, x_l})_\Omega - (\tilde{f}_1^n, \psi_{h, x_l})_\Omega = (\lambda_h, \psi_{h, x_l})_h \geq 0. \]

\[ \square \]
Following Lemma 3.2 we suggest the following definition for the discrete convex set associated to $\lambda^n_h$

**Definition 3.3.** Let, for all $p \geq 1$,

$$
\Lambda^p_h := \left\{ v_h \in X^n_h; (v_h, \psi_h, x_l)_h \geq 0 \quad \forall x_l \in V_{d}^{\text{int}}, (v_h, \psi_h, x_l)_h = 0 \quad \forall x_l \in V_{d}^{\text{ext}} \right\}. 
$$

(7.3)

**Remark 3.4.** Observe that $\Lambda^p_h \subset \Lambda$ for $p \geq 2$. In the case $p = 1$, $\Lambda^p_h$ reduces to

$$
\Lambda_1^p = \left\{ v_h \in X_0; v_h(a) \geq 0 \quad \forall a \in V_h^{\text{int}} \right\} \subset \Lambda.
$$

(7.8)

For $p = 1$, the construction above provides the positivity of the discrete Lagrange multiplier $\lambda^n_h$ in internal vertices of the mesh. In the case $p \geq 2$, the positivity of $\lambda^n_h$ in $\Lambda^p_h$ only holds in a weak sense, which will in particular allow for the equivalence stated in Lemma 3.5 below. We also note that for any $\lambda^n_h \in \Lambda^p_h$ and any $v_h \in K^p_{gh}$,

$$
\langle \lambda^n_h, v^n_{1h} - v^n_{2h} \rangle_h = \sum_{x_l \in V_{d}^{\text{int}}} (v^n_{1h} - v^n_{2h})(x_l) \langle \chi^n_h, \psi_h, x_l \rangle_h \geq 0.
$$

(7.9)

It will be useful to also consider the discrete formulation corresponding to problem (2.4). Given $(u^n_{1h}, u^n_{2h}) \in K^p_{gh}$, it consists, for each $n = 1 \cdots N$, in searching $(u^n_{1h}, u^n_{2h}, \lambda^n_h) \in X^n_h \times X^n_{0h} \times \Lambda^p_h$ such that for all $(z_{1h}, z_{2h}, \chi_h) \in X^n_{0h} \times X^n_{0h} \times \Lambda^p_h$,

$$
\frac{1}{\Delta t} N_{\text{ext}} \sum_{\alpha=1}^{2} (u^n_{\alpha h} - u^{\alpha-1}_{\alpha h}, z_{\alpha h})_{\Omega} + \sum_{\alpha=1}^{2} \mu_\alpha (\nabla u^{\alpha h}, \nabla z_{\alpha h})_{\Omega} - \langle \lambda^n_h, z_{1h} - z_{2h} \rangle_h = \sum_{\alpha=1}^{2} (\tilde{f}^\alpha, z_{\alpha h})_{\Omega}.
$$

(7.10)

Let us also construct the basis $(\Theta_h, \chi_h)_{1 \leq l \leq \mathcal{N}^p_h}$ of $X^n_h$, dual to $(\psi_h, x_l)_{1 \leq l \leq \mathcal{N}^p_h}$, satisfying

$$
\langle \Theta_h, \chi_h \rangle_{h} = 1 \quad \forall x_l \in V_{d}^{\text{int}},
$$

$$
\langle \Theta_h, \psi_h, x_l \rangle_{h} = 0 \quad \forall x_l \in V_{d}^{\text{ext}}, x_l \neq x_i.
$$

(7.11)

as in [16]. Note that each vector $\Theta_h, x_l$ of the dual basis can be determined by inverting a diagonal (lumped mass) matrix for $p = 1$ and the finite element mass matrix for $p \geq 2$; importantly, all $\Theta_h, x_l$, $1 \leq l \leq \mathcal{N}^p_h$, belong to $\Lambda^p_h$. Note also that the support of $\Theta_h, x_l$ is typically not local. We can now link formulations (7.3) and (7.10):

**Lemma 3.5.** Let $1 \leq n \leq N$ be a time step. For any solution $(u^n_{1h}, u^n_{2h}, \lambda^n_h)$ of problem (7.10), the pair $(u^n_{1h}, u^n_{2h})$ is a solution of problem (7.3). Conversely, for any solution $(u^n_{1h}, u^n_{2h})$ of problem (7.3), defining the function $\lambda^n_h = \lambda^n_{\alpha h}$, $\alpha = 1, 2$, by (7.4), the triple $(u^n_{1h}, u^n_{2h}, \lambda^n_h)$ is a solution to problem (7.10).

**Proof.** For the case $p = 1$, the proof is a direct extension of [46, Lemma 13] and for $p \geq 2$ it employs the arguments of [16, Lemma 2.3]. Let $p \geq 1$ and let $(u^n_{1h}, u^n_{2h}, \lambda^n_h)$ be the solution of problem (7.10). The first lines of [16, Lemma 2.3] prove that the discrete vector $u^n_h$ is an element of $K^p_{gh}$. Now, we prove (3.3). Let $(v_{1h}, v_{2h}) \in K^p_{gh}$. Taking $z_{1h} := v_{1h} - v_{1h}^{n-1} \in X^n_{0h}$ and $z_{2h} := v_{2h} - v_{2h}^{n-1} \in X^n_{0h}$ as test functions in (7.10) provides

$$
\langle \lambda^n_h, v_{1h} - v_{2h} \rangle_h - \langle \lambda^n_h, u^n_{1h} - u^n_{2h} \rangle_h = a(u^n_h, v_{1h} - v_{2h})_\Omega + c_n(u^n_h - u^{n-1}_h, v_{1h} - v_{2h})_\Omega.
$$

(7.12)

Using (7.9) with $\lambda^n_h \in \Lambda^p_h$ and $v^n_h \in K^p_{gh}$ and taking $\chi_h = 0 \in \Lambda^p_h$ in (7.10) gives

$$
\langle \lambda^n_h, v_{1h} - v_{2h} \rangle_h \geq 0, \quad \langle -\lambda^n_h, v_{1h} - v_{2h} \rangle_h \geq 0.
$$

(7.13)

Combining (7.12) and (7.13) provides (7.3). Conversely, let $(u^n_{1h}, u^n_{2h}) \in K^p_{gh}$ be the solution of the reduced problem (7.3) and let $(z_{1h}, z_{2h}) \in X^n_{0h} \times X^n_{0h}$ be arbitrary. The Lagrange multiplier $\lambda^n_h$ defined by (7.4) combined with Lemma 3.1 and Lemma 3.2 yields $\lambda^n_h \in \Lambda^p_h$. Next, considering the first line of (7.4) with $\alpha = 1, 2$ and subtracting these
equations gives the first line of (3.10). It remains to prove the second line of (3.10). Let now \((v_{1h}, v_{2h}) \in \mathcal{K}^p_{gh}\). The first line in (3.10) now implies (3.12) and the reduced problem (3.3) yields
\[
- \langle \lambda_h^n, u_{1h}^n - u_{2h}^n \rangle_h + \langle \lambda_h^n, v_{1h} - v_{2h} \rangle_h \geq 0 \quad \forall (v_{1h}, v_{2h}) \in \mathcal{K}^p_{gh}. \tag{3.14}
\]
For \(v_{1h} := u_{1h}^n - \sum_{x_t \in \mathcal{V}^{d,\text{int}}_p} u_{1h}(x_t) \psi_{h,x_t} \in \mathcal{X}^p_{gh}\) and \(v_{2h} := 0 \in \mathcal{X}^p_{0h}\), \((v_{1h}, v_{2h}) \in \mathcal{K}^p_{gh}\), and using the definition of \(\Lambda^p_h\), we have \(\langle \lambda_h^n, v_{1h} - v_{2h} \rangle_h = 0\) and the inequality (3.14) yields \(- \langle \lambda_h^n, u_{1h}^n - u_{2h}^n \rangle_h \geq 0\). To conclude the proof, we use (3.9) with \(u_{h}^n \in \mathcal{K}^p_{gh}\) and for any \(\chi_h \in \Lambda^p_h\).

\(\square\)

As a consequence of Lemma 3.5 and Proposition 1, problem (3.10) is well-posed and admits a unique weak solution for each \(n = 1, \ldots, N_t\). We finish this section by the following remark:

**Remark 3.6.** Taking in (3.10) \(\chi_h = 0\) and next \(\chi_h = 2\lambda^p_h \in \Lambda^p_h\) gives \(\langle \lambda^p_h, u_{1h}^n - u_{2h}^n \rangle_h = 0\). As \(u_{h}^n \in \mathcal{K}^p_{gh}\) and \(\lambda^p_h \in \Lambda^p_h\), we obtain a discrete equivalent of the complementarity condition (2.5) valid for all polynomial degrees \(p \geq 1\):
\[
\langle u_{1h}^n - u_{2h}^n \rangle(x_t) \geq 0 \quad \forall x_t \in \mathcal{V}^{d,\text{int}}_d, \langle \lambda^p_h, \psi_h, x_t \rangle_h \geq 0, \quad \forall x_t \in \mathcal{V}^{d,\text{ext}}_d, \langle \lambda^p_h, u_{1h}^n - u_{2h}^n \rangle_h = 0.
\tag{3.15}
\]

### 3.3 Numerical resolution and discrete complementarity constraints

Let \(n\) be fixed in \(\{1, \ldots, N_t\}\). We write in an algebraic form the discrete problem (3.10), using the expression (3.15) for the constraints. We employ the subset \((\Theta_h, x_t)_{1 \leq i \leq N^p_d, \text{int}}\) of the basis \((\Theta_h, x_t)_{1 \leq i \leq N^p_d}\) of \(\mathcal{X}^p_h\), dual to \((\psi_h, x_t)_{1 \leq i \leq N^p_d, \text{int}}\) in the sense of (3.11). For the first component of the discrete solution \(u_{1h}^n \in \mathcal{X}^p_{gh}\), we use the lifting \(u_{1h}^n = u_{1h}^* + g\) where \(u_{1h}^* \in \mathcal{X}^p_{0h}\) and \(g > 0\) is the constant boundary value. The algebraic representation of the lifting is denoted by \(X_{1h}^n \in \mathbb{R}^{N^p_d, \text{int}}\), so that
\[
u_{1h}^n = \sum_{l=1}^{N^p_d, \text{int}} (X_{1h}^n)_l \psi_{h,x_t} + g \quad \text{where} \quad (X_{1h}^n)_l = u_{1h}^*(x_t). \tag{3.16}
\]

The second component of the discrete solution \(u_{2h}^n\) is expressed in the Lagrange basis \((\psi_h, x_t)_{1 \leq i \leq N^p_d, \text{int}}\) as
\[
u_{2h}^n = \sum_{l=1}^{N^p_d, \text{int}} (X_{2h}^n)_l \psi_{h,x_t} \quad \text{where} \quad (X_{2h}^n)_l = u_{2h}^*(x_t). \tag{3.17}
\]

The initial value \(u_{h}^0 \in \mathcal{K}^p_{gh}\) is decomposed in the same way into \(u_{1h}^0 + g, u_{2h}^0\), and \((u_{1h}^0, u_{2h}^0) \in [\mathcal{X}^p_{0h}]^2\) is represented by \(X^0_h = [X_{1h}^0, X_{2h}^0]^T \in \mathbb{R}^{2N^p_d, \text{int}}\). The discrete Lagrange multiplier \(\lambda^p_h\) is decomposed in the basis \((\Theta_h, x_t)_{1 \leq i \leq N^p_d}\) as
\[
\lambda^p_h = \sum_{l=1}^{N^p_d, \text{int}} (X_{3h}^n)_l \Theta_{h,x_t} \quad \text{with} \quad X_{3h}^n \in \mathbb{R}^{N^p_d, \text{int}}, \tag{3.18}
\]

because \(\lambda^p_h \in \Lambda^p_h\) and thus the components for \(x_t \in \mathcal{V}^{d,\text{ext}}_d\) are 0.

In algebraic form, the first line of (3.10) reads
\[
\mathbb{E}^p X_h = F^n,
\]
where \(X_h^n := [X_{1h}^n, X_{2h}^n, X_{3h}^n]^T \in \mathbb{R}^{3N^p_d, \text{int}}\) is the unknown algebraic vector and \(\mathbb{E}^p \in \mathbb{R}^{2N^p_d, \text{int}, 3N^p_d, \text{int}}\) is the rectangular matrix defined by
\[
\mathbb{E}^p := \begin{bmatrix}
\mu_1 S + \frac{1}{\Delta t^n} M & 0 & -I_d \\
0 & \mu_2 S + \frac{1}{\Delta t^n} M & +I_d 
\end{bmatrix},
\]
\[ I_d \in \mathbb{R}^{N_d^{p,\text{int}}} \] is the identity matrix, and the finite element mass matrix M and the stiffness matrix S belonging to \( \mathbb{R}^{N_d^{p,\text{int}}} \) are defined by
\[
M_{l,m} := (\psi_h, \psi_{h,m})_\Omega, \quad S_{l,m} := (\nabla \psi_h, \nabla \psi_{h,m})_\Omega, \quad 1 \leq l, m \leq N_d^{p,\text{int}}. \tag{3.19}
\]
The right-hand side vector \( F^n \) is defined by blocks ((3.11) \( \equiv [F^n_1, F^n_2]^T \)) as
\[
(F^n_\alpha)_l := \left( \hat{f}_\alpha + \frac{1}{\Delta t} u^n_{\alpha l}, \psi_{h,x_l} \right)_\Omega \quad 1 \leq l \leq N_d^{p,\text{int}}, \quad \alpha = 1, 2. \tag{3.20}
\]
With \( 1 = (1, 1, \cdots, 1)^T \in \mathbb{R}^{N_d^{p,\text{int}}} \), the first complementarity constraint of (3.15) is expressed as
\[
X^n_{1h} + g1 - X^n_{2h} \geq 0.
\]
Next, using (3.11), the second complementarity constraint of (3.15) is given for any \( x_l \in \mathbb{R}_d^{p,\text{int}} \) by
\[
\langle \lambda^n_l, \psi_h x_l \rangle_h = \sum_{\nu=1}^{N_d^{p,\text{int}}} (X^n_{\nu h})_l \langle \Theta_h x_p, \psi_h x_l \rangle_h = (X^n_{1h})_l \geq 0.
\]
For the last constraint in (3.15), using again (3.11), we get
\[
\langle \lambda^n_l, u^n_{1h} - u^n_{2h} \rangle_h = (X^n_{1h} - X^n_{2h}) \cdot X^n_{3h} + g1 \cdot X^n_{3h}. \tag{3.21}
\]
Thus, for any \( p \geq 1 \), problem (3.10) can be written as: given \( X^0_h \in \mathbb{R}^{2N_d^{p,\text{int}}} \), for \( n = 1, \cdots, N_t \), search \( X^n_h \in \mathbb{R}^{2N_d^{p,\text{int}}} \) such that
\[
\begin{align*}
E^n_{p} X^n_h &= F^n, \\
X^n_{1h} + g1 - X^n_{2h} &\geq 0, \quad X^n_{3h} \geq 0, \quad (X^n_{1h} + g1 - X^n_{2h}) \cdot X^n_{3h} = 0. \tag{3.22}
\end{align*}
\]

**Remark 3.7.** Note that \( u^n_{1h} \) and \( u^n_{2h} \) are expressed in the Lagrange basis \( (\psi_h x_l)_{1 \leq l \leq N_d^{p,\text{int}}} \), while the discrete lagrange multiplier \( \lambda^n_l \) is expressed in a subset \( (\Theta_h x_p)_{1 \leq l \leq N_d^{p,\text{int}}} \) of the dual basis to \( (\psi_h x_l)_{1 \leq l \leq N_d^{p,\text{int}}} \). It is also possible to express \( \lambda^n_l \) in the Lagrange basis \( (\psi_h x_l)_{1 \leq l \leq N_d^{p,\text{int}}} \) of \( X^0_h \), see [49, Sect. 1.2.3]. In such a case, the complementarity constraints are expressed with submatrices of the finite element mass matrix and the identity matrix blocks in the matrix \( E^n_{p} \) are replaced by the mass matrix.

### 3.4 Equivalent rewriting using C-functions

We now express the complementarity constraints given by the second line of (3.22) via non-differentiable equations. Let us recall that a function \( f : (\mathbb{R}^m)^2 \to \mathbb{R}^m \), \( m \geq 1 \), is a C-function or a complementarity function, see [29, 30], if
\[
\forall (x, y) \in (\mathbb{R}^m)^2 \quad f(x, y) = 0 \iff x \geq 0, \quad y \geq 0, \quad x \cdot y = 0.
\]
Examples of C-functions are the min and max functions
\[
(\min \{x, y\})_l := \min \{x_l, y_l\}, \quad (\max \{x, y\})_l := \max \{x_l, y_l\} \quad l = 1, \ldots, m, \tag{3.23}
\]
the Fischer–Burmeister function
\[
(f_{FB}(x, y))_l := \sqrt{x_l^2 + y_l^2} - (x_l + y_l) \quad l = 1, \ldots, m, \tag{3.24}
\]
or the Mangasarian function
\[
(f_{M}(x, y))_l := \xi(|x_l - y_l|) - \xi(y_l) - \xi(x_l) \quad l = 1, \ldots, m,
\]

9
where $\xi : \mathbb{R} \mapsto \mathbb{R}$ is an increasing function satisfying $\xi(0) = 0$. The min function, the max function, the Fischer–Burmeister function, and the Mangasarian function are not Fréchet differentiable everywhere. Let $C$ be any $C$-function satisfying for $m = N^{p,\text{int}}_d \cap X^{n,\text{int}}_h + g \mathbf{1} - X^{n,\text{int}}_h \leq 0 \iff \{X^{n,\text{int}}_h + g \mathbf{1} - X^{n,\text{int}}_h \leq 0, X^{n,\text{int}}_h \leq 0, (X^{n,\text{int}}_h + g \mathbf{1} - X^{n,\text{int}}_h) - X^{n,\text{int}}_h \leq 0 \}$. Then, introducing the function $C : \mathbb{R}^3 N^{p,\text{int}}_d \mapsto \mathbb{R}^3 N^{p,\text{int}}_d$ defined as $C(X^n_h) = C(X^{n,\text{int}}_h + g \mathbf{1} - X^{n,\text{int}}_h, X^{n,\text{int}}_h)$, problem (3.22) can be equivalently rewritten as: given $X^{n,\text{int}}_h \in \mathbb{R}^2 N^{p,\text{int}}_d$, for each $n \geq 1$, search $X^{n,\text{int}}_h \in \mathbb{R}^3 N^{p,\text{int}}_d$ such that
\begin{equation}
\begin{cases}
\mathbf{E}^n_n X^{n,\text{int}}_h = F^n, \\
C(X^{n,\text{int}}_h) = 0.
\end{cases}
\end{equation}

### 3.5 Linearization by semismooth Newton methods

Let a time step $n \geq 1$ be fixed and let $X^{n,\text{int}}_h \in \mathbb{R}^2 N^{p,\text{int}}_d$ be given. We provide in this section the linearization of system (3.25). Observe that the $2N^{p,\text{int}}_d$ first lines of (3.25) are linear and the nonlinearity occurs in the last $N^{p,\text{int}}_d$ lines of (3.25). Even if the function $C$ is not Fréchet differentiable, it is locally Lipschitz and continuous. As a result of the Rademacher theorem (see [50, 29, 30]), the function $C$ is differentiable almost everywhere, or more precisely, it belongs to the class of strong semismooth functions. The semismooth Newton linearization is defined as follows: let an initial guess $X^{n,0}_h \in \mathbb{R}^3 N^{p,\text{int}}_d$ be given; typically, $X^{n,0}_h := X^{n-1}_h$, where $X^{n-1}_h$ is the last iterate from the previous time step (including possibly inexact solvers). At step $k \geq 1$, one looks for $X^{n,k}_h \in \mathbb{R}^3 N^{p,\text{int}}_d$ such that
\begin{equation}
A^{n,k-1}_h X^{n,k}_h = B^{n,k-1}_h,
\end{equation}
where $A^{n,k-1}_h \in \mathbb{R}^3 N^{p,\text{int}}_d \times N^{p,\text{int}}_d$ is a matrix and $B^{n,k-1}_h \in \mathbb{R}^3 N^{p,\text{int}}_d$ is the right-hand side vector given by
\begin{equation}
A^{n,k-1}_h := \begin{bmatrix} \mathbf{J}_C(X^{n,k-1}_h) \\ \mathbf{J}_C(X^{n,k-1}_h) \end{bmatrix},
\end{equation}
and $B^{n,k-1}_h := \mathbf{F}^n - \mathbf{E}^n_n X^{n,k-1}_h - C(X^{n,k-1}_h)$.

Here, the notation $J_C(X^{n,k-1}_h)$ stands for the Jacobian matrix in the sense of Clarke. For example, considering the semismooth min function (3.26), we have, for $p \geq 1$,
\begin{equation}
\min \{ X^{n,\text{int}}_h + g \mathbf{1} - X^{n,\text{int}}_h \} = \min \left\{ \left\{ \begin{array}{l}
\begin{array}{c}
\frac{u^{n,\text{int}}_{1h}(x)}{u^{n,\text{int}}_{2h}(x)}
\end{array}
\end{array},
\begin{array}{c}
\frac{u^{n,\text{int}}_{2h}(x_{N^{p,\text{int}}_d})}{u^{n,\text{int}}_{2h}(x_{N^{p,\text{int}}_d})}
\end{array}
\end{array},
\begin{array}{c}
\frac{u^{n,\text{int}}_{1h}(x_{N^{p,\text{int}}_d})}{u^{n,\text{int}}_{2h}(x_{N^{p,\text{int}}_d})}
\end{array}
\right\},
\begin{array}{c}
\frac{(x_{N^{p,\text{int}}_d})}{(x_{N^{p,\text{int}}_d})}
\end{array}
\right\},
\end{equation}
and if the block matrices $K$ and $G$ in $\mathbb{R}^3 N^{p,\text{int}}_d \times N^{p,\text{int}}_d$ are defined respectively by
\begin{equation}
K := \begin{bmatrix} I_{N^{p,\text{int}}_d} & -I_{N^{p,\text{int}}_d} & -I_{N^{p,\text{int}}_d} \\
0_{N^{p,\text{int}}_d, N^{p,\text{int}}_d} & 0_{N^{p,\text{int}}_d, N^{p,\text{int}}_d} & 0_{N^{p,\text{int}}_d, N^{p,\text{int}}_d}
\end{bmatrix},
\end{equation}
\begin{equation}
G := \begin{bmatrix} 0_{N^{p,\text{int}}_d, N^{p,\text{int}}_d} & 0_{N^{p,\text{int}}_d, N^{p,\text{int}}_d} & 0_{N^{p,\text{int}}_d, N^{p,\text{int}}_d}
\end{bmatrix},
\end{equation}
the $i$th row of the Jacobian matrix in the sense of Clarke $J_C(X^{n,k-1}_h)$ is either given by the $i$th row of $K$ if $u^{n,k-1}_{1h}(x_i) - u^{n,k-1}_{2h}(x_i) \leq (X^{n,k-1}_h)_i$, or by the $i$th row of $G$ if $u^{n,k-1}_{1h}(x_i) - u^{n,k-1}_{2h}(x_i) > (X^{n,k-1}_h)_i$.

For an “exact semismooth Newton” resolution of (3.25), choose a tolerance $\varepsilon_{\text{lin}}$ close to the machine precision and stop the linearization procedure when the relative linearization residual satisfies
\begin{equation}
\frac{\| F^n - \mathbf{E}^n_n X^{n,k}_h \|}{\| C(X^{n,k}_h) \|} \leq \varepsilon_{\text{lin}}.
\end{equation}

### 3.6 Iterative algebraic solvers and inexact linearization

Let a linearization step $k \geq 1$ be fixed and choose an iterative algebraic solver with iteration index $i \geq 0$. Given an initial guess $X^{n,k,0}_h \in \mathbb{R}^3 N^{p,\text{int}}_d$, often taken as $X^{n,k,0}_h := X^{n,k-1}_h$, where $X^{n,k-1}_h$ is the last available
iterate from the previous semismooth Newton step (including possibly inexact algebraic solver), the residual in (3.26) is defined by
\[ R_{h}^{n,k,i} := B^{n,k-1} - \Delta X_{h}^{n,k,i}. \] (3.31)
In fact, the residual \( R_{h}^{n,k,i} \in \mathbb{R}^{N_{h}^{p,\text{int}}} \) is a block vector
\[ R_{h}^{n,k,i} := \begin{bmatrix} R_{h}^{n,k,i} \mid R_{2h}^{n,k,i} \mid R_{3h}^{n,k,i} \end{bmatrix}^T, \]
where \( R_{\alpha h}^{n,k,i} \in \mathbb{N}_{h}^{p,\text{int}}, \alpha = 1, 2, \) are the components associated to the block equation in (3.22), whereas \( R_{3h}^{n,k,i} \in \mathbb{N}_{h}^{3,\text{int}} \) is associated with the block inequality (constraints) in (3.22).

"Inexact semismooth Newton" resolution of (3.25) consists in, on each step \( i \), the algebraic solver step. The functional representations of the vectors \( u_{h}^{n-1}, u_{2h}^{n-1} \) are given as in (3.16) and (3.17), and the function of \( \lambda_{h}^{n,k,i} \) denoted by \( \lambda_{h}^{n,k,i} \) is given as in (3.18). Obviously, \( (u_{1h}^{n,k,i}, u_{2h}^{n,k,i}, \lambda_{h}^{n,k,i}) \in X_{gh}^{p} \times X_{0h}^{p} \times X_{h}^{p} \) \( \forall 1 \leq n \leq N_{t} \). Next, we associate to the functions in space \( u_{1h}^{n,k,i} \in X_{gh}^{p} \) and \( u_{2h}^{n,k,i} \in X_{0h}^{p} \), 1 \( \leq n \leq N_{t} \), their space-time representations \( u_{1h,T}^{n,k,i}, u_{2h,T}^{n,k,i} \)
\[ u_{1h,T}^{n,k,i}(t_{n}) := \frac{u_{1h}^{n,k,i} - u_{1h}^{n-1}}{\Delta t_{n}} (t - t_{n}) + u_{1h}^{n,k,i} \quad \forall 1 \leq n \leq N_{t}, \]
\[ u_{2h,T}^{n,k,i}(t_{n}) := \frac{u_{2h}^{n,k,i} - u_{2h}^{n-1}}{\Delta t_{n}} (t - t_{n}) + u_{2h}^{n,k,i} \quad \forall 1 \leq n \leq N_{t}. \]

Concerning the discrete Lagrange multiplier \( \lambda_{h}^{n,k,i} \in X_{h}^{p} \), its space-time representation is defined by a piecewise constant-in-time function \( \lambda_{h,T}^{n,k,i} \)
\[ \lambda_{h,T}^{n,k,i}(t_{n}) := \lambda_{h}^{n,k,i}. \]
Note that this construction ensures that \( u_{\alpha h r}^{k, i} = 1, 2 \), are continuous and piecewise affine in time, so that \( \partial_t u_{\alpha h r}^{k, i} \in L^2(0, T; H^{-1}(\Omega)) \). In the expressions of \( u_{1h r}^{k, i}, u_{2h r}^{k, i} \), and \( h_{\alpha r}^{k, i} \), the indices \( k, i \) are kept to indicate the presence of inexact solvers; more precisely, \( u_{\alpha h}^{n-1} \) are equal to \( u_{\alpha h}^{n-1, k, i} \) for the last iterates \( k \) and \( i \) when the stopping criteria are met. For each time step \( n \), we also denote

\[
\partial_t u_{1h r}^{n, k, i} |_{I_n} = \frac{1}{\Delta t_n} \left( u_{1h r}^{n, k, i} - u_{1h r}^{n-1} \right), \quad \partial_t u_{2h r}^{n, k, i} |_{I_n} = \frac{1}{\Delta t_n} \left( u_{2h r}^{n, k, i} - u_{2h r}^{n-1} \right).
\]

### 4.2 Representation of the residual

We first start by giving a functional representation to (3.31), following [55]. We associate respectively with \( R_{1h}^{n, k, i} \) and \( R_{2h}^{n, k, i} \) elementwise discontinuous polynomials \( r_{1h}^{n, k, i} \) and \( r_{2h}^{n, k, i} \) of degree \( p \geq 1 \) that vanish on the boundary of \( \Omega \). These can be easily computed solving on each element \( K \in T_h \) a small problem with an element mass matrix given as follows. For \( x_l \in V_d^{\text{int}} \), denote by \( N_{h, x_l} \) the number of mesh elements forming the support of the basis function \( \psi_{h, x_l} \). Then, for all \( K \in T_h \) and for all \( \alpha \in \{ 1, 2 \} \), define \( r_{\alpha h}^{n, k, i} |_K \in \mathbb{P}_p(K) \) such that:

\[
(r_{\alpha h}^{n, k, i}, \psi_{h, x_l})_K := \frac{(R_{\alpha h}^{n, k, i})_l}{N_{h, x_l}} \quad \text{and} \quad r_{\alpha h}^{n, k, i}|_{\partial K \cap \partial T} := 0
\]

for all Lagrange basis functions \( \psi_{h, x_l} \in \mathcal{X}_h, x_l \in V_d^{\text{int}} \), nonzero on \( K \). It is easily seen that the first \( 2N_0^{\text{int}} \) lines of (3.31) then read

\[
\begin{align*}
\mu_1 \left( \nabla u_{1h r}^{n, k, i}, \nabla \psi_{h, x_l} \right)_\Omega &= \left( \hat{f}_1 + \hat{\lambda}_{h, l}^{n, k, i} - r_{1h}^{n, k, i} - \partial_t u_{1h r}^{n, k, i}, \psi_{h, x_l} \right)_\Omega \quad \forall l = 1, \ldots, N_0^{\text{int}}, \\
\mu_2 \left( \nabla u_{2h r}^{n, k, i}, \nabla \psi_{h, x_l} \right)_\Omega &= \left( \hat{f}_2 - \hat{\lambda}_{h, l}^{n, k, i} - r_{2h}^{n, k, i} - \partial_t u_{2h r}^{n, k, i}, \psi_{h, x_l} \right)_\Omega \quad \forall l = 1, \ldots, N_0^{\text{int}},
\end{align*}
\]  

(4.2)

where

\[
\hat{\lambda}_{h, l}^{n, k, i} = \begin{cases} \lambda_{h, l}^{n, k, i}(x_l) & \text{if } p = 1, \\
\lambda_{h, l}^{n, k, i} & \text{if } p \geq 2. \end{cases}
\]

(4.3)

We also use the shorthand notation:

\[
\begin{align*}
\hat{\lambda}_{h, a}^{n, k, i} &= \begin{cases} \lambda_{h, a}^{n, k, i}(\alpha) & \text{if } p = 1, \\
\lambda_{h, a}^{n, k, i} & \text{if } p \geq 2. \end{cases}
\end{align*}
\]

The functional representation of (3.31) given by (4.2) is essential for our a posteriori analysis as we will see in the sequel.

### 4.3 Flux reconstructions

Our a posteriori analysis relies on the equilibrated flux reconstructions following the concepts of [56, 57, 58, 16]. We construct a discretization flux reconstruction \( \sigma_{\alpha h, \text{disc}}^{n, k, i} \in \mathbf{H}(\text{div}, \Omega) \) and an algebraic error flux reconstruction \( \sigma_{\alpha h, \text{alg}}^{n, k, i} \in \mathbf{H}(\text{div}, \Omega) \). More precisely, the discretization flux reconstruction is obtained by solving mixed finite element systems on the patches \( \omega_{\alpha h}^a \) around the mesh vertices \( \alpha \in V_h \) on the mesh \( T_h \), while the algebraic flux \( \sigma_{\alpha h, \text{alg}}^{n, k, i} \) is obtained via solving local problems on a hierarchy of nested grids. The fluxes \( \sigma_{\alpha h, \text{alg}}^{n, k, i}, \sigma_{\alpha h, \text{disc}}^{n, k, i} \) are reconstructed in the Raviart–Thomas subspaces of \( \mathbf{H}(\text{div}, \Omega) \). The Raviart–Thomas spaces of order \( p \geq 1 \) [59, 60, 61] are defined by

\[
\mathbf{RT}_p(\Omega) := \{ \tau_h \in \mathbf{H}(\text{div}, \Omega), \; \tau_h|_K \in \mathbf{RT}_p(K) \; \forall K \in T_h \},
\]

where

\[
\mathbf{RT}_p(K) := \| \mathbf{P}_p(K) \|^2 + \bar{d} \mathbf{P}_p(K), \quad \text{with } \bar{d} = [x_1, x_2]^T. \]

For \( \alpha \in V_h \), let

\[
\begin{align*}
\mathbf{RT}_p(\omega_{\alpha h}^a) := \{ \tau_h \in \mathbf{H}(\text{div}, \omega_{\alpha h}^a), \; \tau_h|_K \in \mathbf{RT}_p(K), \; \forall K \in T_h \text{ such that } K \subset \omega_{\alpha h}^a \}.
\end{align*}
\]
and let $\mathbb{P}_p(T_h|\omega_h^a)$ stand for piecewise discontinuous polynomials of order $p$ in the patch $\omega_h^a$. Define consequently the spaces $V_h^a$ and $Q_h^a$ by
\[
V_h^a := \{ \tau_h \in RT_p(\omega_h^a), \tau_h \cdot n_{\omega_h^a} = 0 \text{ on } \partial \omega_h^a \}, \quad Q_h^a := \{ q_h \in \mathbb{P}_p(T_h|\omega_h^a), (q_h, 1)_{\omega_h} = 0 \},
\]
when $a \in V_h^{\text{int}}$ and
\[
V_h^a := \{ \tau_h \in RT_p(\omega_h^a), \tau_h \cdot n_{\omega_h^a} = 0 \text{ on } \partial \omega_h \backslash \partial \Omega \}, \quad Q_h^a := \mathbb{P}_p(T_h|\omega_h^a)
\]
when $a \in V_h^{\text{ext}}$.

### 4.3.1 Discretization flux reconstructions

For all time steps $1 \leq n \leq N$, let $\left( u_{1h}^{n,k,i}, u_{2h}^{n,k,i}, \lambda_h^{n,k,i} \right)$ be the approximate solution given by (3.31), verifying in particular (4.2). For each vertex $a \in V_h$ and each $\alpha \in \{1, 2\}$, define $\sigma_{\alpha h, \text{disc}}^{n,k,i,a} \in V_h^a$ and $\gamma_{\alpha h}^{n,k,i,a} \in Q_h^a$ by solving:
\[
\begin{align*}
\left( \sigma_{\alpha h, \text{disc}}^{n,k,i,a}, \tau_h \right)_{\omega_h^a} - \left( \gamma_{\alpha h}^{n,k,i,a}, \nabla \cdot \tau_h \right)_{\omega_h^a} &= - \left( \mu_a \psi_{h,a} \nabla u_{h}^{n,k,i} \cdot \tau_h \right)_{\omega_h^a} \quad \forall \tau_h \in V_h^a, \\
\left( \nabla \sigma_{\alpha h, \text{disc}}^{n,k,i,a}, q_h \right)_{\omega_h^a} &= \left( \tilde{g}_{\alpha h}^{n,k,i,a}, q_h \right)_{\omega_h^a} \quad \forall q_h \in Q_h^a,
\end{align*}
\]
where the spaces $V_h^a$ and $Q_h^a$ are defined by (4.4)–(4.5). The right-hand sides are given as
\[
\tilde{g}_{\alpha h}^{n,k,i,a} := \left( f_{\alpha} - (-1)^{\alpha} n_{\omega_h}^{n,k,i} - n_{\omega_h}^{n,k,i} \cdot \partial_t u_{h,\alpha}^{n,k,i} \right) \psi_{h,a} - \mu_a \nabla u_{h}^{n,k,i} \cdot \nabla \psi_{h,a}.
\]
Note that it follows from (4.2) with the test functions $\psi_{h,a} \in X_h^p$ for all polynomial degrees $p \geq 1$,
\[
\left( \tilde{g}_{\alpha h}^{n,k,i,a}, 1 \right)_{\omega_h^a} = 0 \quad \forall \alpha \in V_h^{\text{int}}.
\]
This implies the Neumann compatibility condition for (4.6). At each time step $1 \leq n \leq N$, the discretization flux reconstruction is defined by
\[
\sigma_{\alpha h, \text{disc}}^{n,k,i,a} := \sum_{\alpha \in V_h} \sigma_{\alpha h, \text{disc}}^{n,k,i,a}.
\]

The following proposition can be shown as in [55, 16]:

**Proposition 2.** The flux reconstruction $\sigma_{\alpha h, \text{disc}}^{n,k,i,a} \in H(\text{div}, \Omega)$ and satisfies the equilibration property
\[
\left( \nabla \sigma_{\alpha h, \text{disc}}^{n,k,i,a}, q_h \right)_K = \left( f_{\alpha} - (-1)^{\alpha} n_{\omega_h}^{n,k,i} - n_{\omega_h}^{n,k,i} \cdot \partial_t u_{h,\alpha}^{n,k,i} \right) \psi_{h,a} - \mu_a \nabla u_{h}^{n,k,i} \cdot \nabla \psi_{h,a} \quad \forall q_h \in \mathbb{P}_p(K), \forall K \in T_h.
\]

### 4.3.2 Algebraic error flux reconstructions

The algebraic error flux reconstructions $\sigma_{\alpha h, \text{alg}}^{n,k,i,\alpha}, \alpha = 1, 2$, are obtained by the methodology of [55] and yield
\[
\sigma_{\alpha h, \text{alg}}^{n,k,i} \in H(\text{div}, \Omega) \quad \text{and} \quad \nabla \sigma_{\alpha h, \text{alg}}^{n,k,i} = r_{\alpha h}^{n,k,i}.
\]

### 4.3.3 Total flux reconstructions

Finally, the total flux reconstructions are the sums
\[
\sigma_{\alpha h}^{n,k,i} := \sigma_{\alpha h, \text{disc}}^{n,k,i} + \sigma_{\alpha h, \text{alg}}^{n,k,i} \quad \alpha = 1, 2,
\]
so that
\[
\left( \nabla \sigma_{\alpha h}^{n,k,i}, q_h \right)_K = \left( f_{\alpha} - (-1)^{\alpha} n_{\omega_h}^{n,k,i} - n_{\omega_h}^{n,k,i} \cdot \partial_t u_{h,\alpha}^{n,k,i} \right) \psi_{h,a} - \mu_a \nabla u_{h}^{n,k,i} \cdot \nabla \psi_{h,a} \quad \forall q_h \in \mathbb{P}_p(K), \forall K \in T_h.
\]

For $\alpha = 1, 2$, all these fluxes are extended piecewise constant in time as
\[
\sigma_{\alpha h}^{k,i}(t_n) = \sigma_{\alpha h}^{n,k,i} \quad \sigma_{\alpha h, \text{disc}}^{k,i}(t_n) = \sigma_{\alpha h, \text{disc}}^{n,k,i} \quad \sigma_{\alpha h, \text{alg}}^{k,i}(t_n) = \sigma_{\alpha h, \text{alg}}^{n,k,i}, \forall 1 \leq n \leq N_t.
\]

As a shorthand notation, we will also use $\sigma_{\alpha h}^{k,i} := \sigma_{\alpha h}^{n,k,i}|_{t_n}$.
4.4 An a posteriori error estimate for \( p = 1 \) and exact solvers

In this section, we establish an a posteriori error estimate between the exact solution \( \mathbf{u} \in \mathcal{K}_g^1 \) given by (1.2) and the approximate numerical solution for \( p = 1 \) when the semismooth Newton solver and the iterative algebraic solver have converged. In this case, we discard the indices \( k \) and \( i \). Note that when \( p = 1 \), the constraints in (3.15) imply that the approximate solution is conforming in the sense that \( \mathbf{u}_{h\tau} \in \mathcal{K}_g^1 \) and \( \lambda_{h\tau} \in \Psi \).

Definition 4.1. Let \( 1 \leq n \leq N_t \), \( K \in \mathcal{T}_h \), and \( \alpha = 1, 2 \). We define the residual estimator \( \eta_{\text{R},K,\alpha}^n \), the flux estimator \( \eta_{\text{F},K,\alpha}^n \), the constraint estimator \( \eta_{\text{C},K}^n \), and the data oscillation estimator \( \eta_{\text{osc},K,\alpha}^n \) by the temporal functions, for all \( t \in I_n \),

\[
\eta_{\text{R},K,\alpha}^n(t) := \frac{h_K}{\mu_\alpha} \| \tilde{f}_\alpha^n - \partial_t u_{ah\tau}^n - (-1)^{\alpha} \lambda_h^n - \nabla \cdot \sigma_{ah\tau}^n \|_K, \tag{4.12}
\]

\[
\eta_{\text{F},K,\alpha}^n(t) := \| \mu_\alpha \nabla u_{ah\tau}^n + \mu_\alpha \frac{1}{2} \sigma_{ah\tau}^n \|_K, \tag{4.13}
\]

\[
\eta_{\text{C},K}^n(t) := 2 (\lambda_h, u_{1h\tau}^n - u_{2h\tau}^n)_K, \tag{4.14}
\]

\[
\eta_{\text{osc},K,\alpha}^n(t) := C_{\text{PF}} h_{\Omega} \mu_\alpha \| f_a - \tilde{f}_a^n \|_K. \tag{4.15}
\]

Remark 4.2. The estimators (4.12)–(4.15) are an extension of the estimators of [47] derived in the case of elliptic variational inequalities to the parabolic case. They reflect various violations of physical properties of the approximate solution \((u_{1h\tau}^n, u_{2h\tau}^n, \lambda_h^n)\): \( \eta_{\text{R},K,\alpha}^n \) and \( \eta_{\text{F},K,\alpha}^n \) represent the nonconformity of the flux, i.e., the fact that \( -\mu_\alpha \nabla u_{ah\tau}^n \notin L^2(0,T; \mathbf{H}(\text{div}, \Omega)) \); \( \eta_{\text{C},K}^n \) reflects inconsistencies in the complementarity conditions at the discrete level, i.e., the fact that \( (u_{1h\tau}^n - u_{2h\tau}^n, \lambda_h^n) \neq 0 \). Note that the last constraint in (3.15) for \( p = 1 \) requires that \((u_{1h\tau}^n - u_{2h\tau}^n, \lambda_h^n)\) vanishes at each vertex of \( \mathcal{T}_h \) but not everywhere in \( \Omega \). Finally, \( \eta_{\text{osc},K,\alpha}^n \) represents the local distance between the right hand side and its time-averages over \( I_n \). Note that this latter term is an estimator of \( \| f_a - \tilde{f}_a^n \|_{H^{-1}(\Omega)} \) (see (4.21) further) with a rather pessimistic constant, see the discussion in [42, Rem. 5.4] and the references therein).

4.4.1 A control of the energy error

Recall the Poincaré–Friedrichs and the Poincaré–Wirtinger inequalities, cf. [62, 63]. Denoting by \( \pi_\Omega \) the mean value of \( v \) over domain \( \Omega \) and \( h_\Omega \) the diameter of \( \Omega \),

\[
\| v \|_\Omega \leq C_{\text{PF}} h_\Omega \| \nabla v \|_\Omega \quad \forall v \in H_0^1(\Omega), \tag{4.16a}
\]

\[
\| v - \pi_\Omega v \|_\Omega \leq C_{\text{PW}} h_\Omega \| \nabla v \|_\Omega \quad \forall v \in H^1(\Omega). \tag{4.16b}
\]

We then have:

Theorem 4.3 (case \( p = 1 \) and exact solvers). Let \( \mathbf{u} \in \mathcal{K}_g^1 \) be the exact solution given by (1.2). Let \( \mathbf{u}_{h\tau} \in \mathcal{K}_g^1 \) and \( \lambda_{h\tau} \in \Psi \) be the approximate solutions for \( p = 1 \) and exact solvers. Consider the equilibrated flux reconstructions \( \sigma_{ah\tau} \in L^2(0,T; \mathbf{H}(\text{div}, \Omega)) \) given by (4.9), (4.11). Using the error estimators defined by (4.12)–(4.15), there holds

\[
\left\| \mathbf{u} - \mathbf{u}_{h\tau} \right\|_{\Omega,T}^2 + \left\| (\mathbf{u} - \mathbf{u}_{h\tau}) (\cdot, T) \right\|_{\Omega}^2 \leq \eta^2 :=
\begin{align*}
&\left\{ \left( \frac{N_t}{\sum_{n=1}^{N_t} \sum_{\alpha=1}^{2} \sum_{K \in \mathcal{T}_h} \eta_{\text{R},K,\alpha}^n + \eta_{\text{F},K,\alpha}^n} \right)^{\frac{1}{2}} + \left( \frac{1}{\sum_{n=1}^{N_t} \sum_{\alpha=1}^{2} \sum_{K \in \mathcal{T}_h} \eta_{\text{osc},K,\alpha}^n(t) dt} \right)^{\frac{1}{2}} \right\}^2 \\
&+ \sum_{n=1}^{N_t} \sum_{\alpha=1}^{2} \sum_{K \in \mathcal{T}_h} \eta_{\text{C},K}^n(t) dt + \left\| (\mathbf{u} - \mathbf{u}_{h\tau}) (\cdot, 0) \right\|_{\Omega}^2.
\end{align*}
\tag{4.17}
\]

To prove Theorem 4.3, we first introduce the following lemma.
Lemma 4.4. Let a and b be the forms defined in (2.3). Let \( u \in K^1 \) be the weak solution from (1.2) and let \( y := (y_1, y_2) \in K^1 \) be arbitrary. Then, for the vector \( y^* := (y_1^*, y_2^*) := (u_1 - y_1, u_2 - y_2) \in [L^2(0, T; H^1_0(\Omega))]^2 \), there holds

\[
A := \int_0^T \left( \langle f, y^* \rangle - (\partial_t u_{h\tau}, y^*)_\Omega - a(u_{h\tau}, y^*) + b(y^*, \lambda_{h\tau}) \right)(t) \, dt
\]

\[
\leq \left( \sum_{n=1}^{N_t} \int_{I_n} \sum_{K \in T_h} \left( \eta_{K, a}^n \right)^2 (t) \, dt \right)^{\frac{1}{2}} + \left( \sum_{n=1}^{N_t} \int_{I_n} \sum_{K \in T_h} \left( \eta_{osc,K,a}^n \right)^2 (t) \, dt \right)^{\frac{1}{2}} \| y^* \|_{L^2(T)}.
\]

(4.18)

Proof. Adding and subtracting \( \sigma_{a h \tau}(t) \in H(\text{div}, \Omega) \) and using the Green formula with \( y^n_\alpha(t) \in H^1_0(\Omega), \alpha = 1, 2 \), and employing the decomposition \( f_\alpha = f^n_\alpha + (f_\alpha - f^n_\alpha) \), we have

\[
A = \int_0^T \sum_{\alpha=1}^2 \left( \bar{f}^n_\alpha - \partial_t u_{a h \tau} - \nabla \cdot \sigma_{a h \tau} - (-1)^\alpha \lambda_{h \tau} y^n_\alpha \right)_\Omega(t) \, dt
\]

\[
- \int_0^T \sum_{\alpha=1}^2 \left( \mu_\alpha \frac{1}{2} \nabla u_{a h \tau} + \mu_\alpha \frac{1}{2} \sigma_{a h \tau} + \mu_\alpha \frac{1}{2} \nabla y^n_\alpha \right)_\Omega(t) \, dt + \int_0^T \sum_{\alpha=1}^2 \left( f_\alpha - f^n_\alpha, y^n_\alpha \right)_\Omega(t) \, dt.
\]

Let \( \alpha = 1, 2, \) \( 1 \leq n \leq N_t, \) \( t \in I_n, \) and \( K \in T_h \) be fixed. Denoting by \( \pi_K \) the mean value over \( K \) of \( w \in L^2(\Omega) \) and using the property (4.10), one has

\[
\left( \bar{f}^n_\alpha - \partial_t u_{a h \tau} - (-1)^\alpha \lambda_{h \tau} \right)_K(t) = \left( \mu_\alpha \frac{1}{2} \bar{f}^n_\alpha - \partial_t u_{a h \tau} - (-1)^\alpha \lambda_{h \tau} \right)_K(t).
\]

Using the Cauchy–Schwarz inequality and next the Poincaré–Wirtinger inequality (4.16b) with \( C_{PW} = \frac{1}{2} \) for the convex mesh element \( K \), we get

\[
\left( \bar{f}^n_\alpha - \partial_t u_{a h \tau} - (-1)^\alpha \lambda_{h \tau} \right)_K(t) \leq \eta_{K, a}^n \mu_\alpha \frac{1}{2} \nabla y^n_\alpha(t).
\]

(4.19)

Next, as a result of the Cauchy–Schwarz inequality, we have

\[
\left( \mu_\alpha \frac{1}{2} \nabla u_{a h \tau} + \mu_\alpha \frac{1}{2} \sigma_{a h \tau} + \mu_\alpha \frac{1}{2} \nabla y^n_\alpha \right)_K(t) \leq \eta_{F,K,a}^n \mu_\alpha \frac{1}{2} \nabla y^n_\alpha(t).
\]

(4.20)

Finally, the Cauchy–Schwarz inequality and the Poincaré–Friedrichs inequality over the entire computational domain \( \Omega \) give

\[
\left( f_\alpha - \bar{f}^n_\alpha, y^n_\alpha \right)_\Omega(t) \leq C_{PF} h_{\Omega} \mu_\alpha \frac{1}{2} \left\| f_\alpha - \bar{f}^n_\alpha \right\|_{L^2(\Omega)} \left\| \mu_\alpha \frac{1}{2} \nabla y^n_\alpha \right\|_{L^2(\Omega)}(t)
\]

\[
= \left( \sum_{K \in T_h} \left( \eta_{osc,K,a}^n \right)^2(t) \right)^{\frac{1}{2}} \left\| \mu_\alpha \frac{1}{2} \nabla y^n_\alpha \right\|_{L^2(\Omega)}(t).
\]

(4.21)

Therefore, combining (4.19)–(4.21) and applying the Cauchy–Schwarz inequality, we get the desired result. □

Proof of Theorem 4.3. Observe that [64, Theorem 5.9.3] gives

\[
\frac{1}{2} \left\| (u - u_{h\tau})(\cdot, T) \right\|^2_{\Omega} = \frac{1}{2} \left\| (u - u_{h\tau})(\cdot, 0) \right\|^2_{\Omega} + \int_0^T \sum_{\alpha=1}^2 (\partial_t(u_\alpha - u_{a h \tau}), u_\alpha - u_{a h \tau})(t) \, dt.
\]

(4.22)

Then posing \( B := \left\| u - u_{h\tau} \right\|^2_{L^2(T)} + \frac{1}{2} \left\| (u - u_{h\tau})(\cdot, T) \right\|^2_{\Omega}, \) using definition (2.7) and (4.22), we get

\[
B = \int_0^T \left( u(u - u_{h\tau}, u - u_{h\tau}) + (\partial_t u, u - u_{h\tau}) - (\partial_t u_{h\tau}, u - u_{h\tau})_\Omega \right)(t) \, dt + \frac{1}{2} \left\| (u - u_{h\tau})(\cdot, 0) \right\|^2_{\Omega}.
\]
Then, using the weak formulation (1.2) with \( v = u_{hT} \in K^1_g \), we obtain
\[
B \leq \int_0^T \left( (f - \partial_t u_{hT}, u - u_{hT})_\Omega - a(u_{hT}, u - u_{hT}) \right) (t) \, dt + \frac{1}{2} \|(u - u_{hT}) (\cdot, 0)\|_\Omega^2.
\]

Next, adding and subtracting \( \int_0^T b(u - u_{hT}, \lambda_{hT})(t) \, dt \) and noting that \((-\lambda_{hT}, u_0 - u_T) \leq 0 \) for a.e \( t \in [0, T] \) because \( \lambda_{hT} \in \Psi \), we obtain
\[
B \leq \int_0^T \left( (f - \partial_t u_{hT}, u - u_{hT})_\Omega - a(u_{hT}, u - u_{hT}) + b(u - u_{hT}, \lambda_{hT}) \right) (t) \, dt + \frac{1}{2} \|(u - u_{hT}) (\cdot, 0)\|_\Omega^2.
\]

Finally, employing Lemma 4.4 with \( y = u_{hT} \in K^1_g \) and using the Young inequality \( A_1 A_2 \leq \frac{1}{2} (A_1^2 + A_2^2) \), \( \forall A_1, A_2 \geq 0 \), we get the desired result.

**4.4.2 A control of the temporal derivative error**

So far, we have established an a posteriori error estimate between the exact solution \( u \in K^1_g \) and its approximate solution \( u_{hT} \in K^1_g \) in the energy norm. As we mentioned in the introduction, we cannot easily estimate the norm \( \|\partial_t (u - u_{hT})\|_{L^2(0,T)} \). We now give our replacement result. Given \( u \in K^1_g \) and for the approximate solution \( u_{hT} \in K^1_g \), let \( z \in K^1_g \) be such that, for all \( v \in K^1_g \),
\[
\int_0^T a(z - u, v - z)(t) \, dt \geq - \int_0^T \sum_{\alpha=1}^2 \langle \partial_t (u_{n\alpha} - u_{hT}), v_{n\alpha} - z_{n\alpha} \rangle(t) \, dt, \tag{4.23}
\]
and its
\[
z(0) = u_{hT}(0) \in K_g.
\]

As a result of the Lions–Stampacchia theorem, problem (4.23) is well posed. Now, we give an a posteriori error estimate on the error \( \|u - z\|_{\Omega, T} \).

**Theorem 4.5** (case \( p = 1 \) and exact solvers). Let \( u \in K^1_g \) be the solution of the weak formulation given by (1.2) and let \( z \in K^1_g \) be the solution of (4.23). Assume that the hypotheses of Theorem 4.3 hold and let the total estimator \( \eta \) be defined by (4.17). Then
\[
\|u - z\|_{\Omega, T} \leq 2\eta.
\]

**Proof.** Setting \( w^* := u - z \), we have \( \|w^*\|^2_{\Omega, T} = \int_0^T a(u - z, u - z) \, dt \). For \( v = u \in K^1_g \), we in turn get from (4.23)
\[
\|w^*\|^2_{\Omega, T} \leq \int_0^T \left( \langle \partial_t (u - u_{hT}), w^* \rangle + b(w^*, \lambda_{hT}) \right) (t) \, dt + \int_0^T (a(u - u_{hT}, w^*) - a(u - u_{hT}, w^*)) (t) \, dt.
\]

Employing the weak formulation (1.2) with \( v = z \in K^1_g \) we obtain
\[
\|w^*\|^2_{\Omega, T} \leq \int_0^T \left( (f - \partial_t u_{hT}, w^*)_\Omega + b(w^*, \lambda_{hT}) - a(u_{hT}, w^*) \right) (t) \, dt. \tag{4.24}
\]

To bound the three first terms of (4.24), we employ Lemma 4.4 with \( y = z \in K^1_g \) and next the Young inequality \( AB \leq \frac{1}{2} A^2 + B^2 \) to see
\[
\|w^*\|^2_{\Omega, T} \leq \left( \sum_{n=1}^{N_t} \int_{I_n} \sum_{K \in T_h} \sum_{\alpha=1}^2 (\eta^n_{R,K,\alpha} + \eta^n_{F,K,\alpha})^2 (t) \, dt \right)^{\frac{1}{2}} + \left( \int_0^T \sum_{\alpha=1}^2 (\eta^n_{osc,K,\alpha})^2 (t) \, dt \right)^{\frac{1}{2}} + \frac{1}{4} \|w^*\|^2_{\Omega, T} - \int_0^T a(u - u_{hT}, w^*) (t) \, dt.
\]

\( \tag{4.25} \)
The Cauchy–Schwarz inequality and the Young inequality give

\[- \int_0^T a(u - u_{h\tau}, w^*)(t) \, dt \leq \|u - u_{h\tau}\|_{\Omega, T}^2 \|w^*\|_{\Omega, T} \leq \|u - u_{h\tau}\|_{\Omega, T}^2 + \frac{1}{4} \|w^*\|_{\Omega, T}^2. \tag{4.26}\]

Finally, combining (4.25) and (4.26) with (4.17), we get \( \|w^*\|_{\Omega, T}^2 \leq 4\eta^2 \) which is the desired result. \( \square \)

Combining Theorems 4.3 and 4.5, we infer

\textbf{Corollary 4.6} (case \( p = 1 \) and exact solvers). Assume the hypotheses of Theorem 4.5. Then

\[ \|u - u_{h\tau}\|_{\Omega, T}^2 + \|u - z\|_{\Omega, T}^2 + \|(u - u_{h\tau}) (\cdot, T)\|_{\Omega}^2 \leq 5\eta^2. \tag{4.27}\]

In Lemma 4.7, we show that the error measure \( \|u - z\|_{\Omega, T} \) is linked to the temporal derivative error, but we could not obtain the (more interesting) converse estimate that would allow to control the temporal derivative error by the estimators.

\textbf{Lemma 4.7.} Assuming the hypotheses of Theorem 4.5 and denoting by \( \delta := 2/ \min \left( \mu_1, \mu_2 \right) \) we have

\[ \|u - z\|_{\Omega, T} \leq \delta \left( \left( \int_0^T \| \partial_t (u_{a\alpha} - u_{a\alpha h\tau}) \|_{H^{-1}(\Omega)}^2 (t) \, dt \right)^{rac{1}{2}} + \left( \int_0^T \| \lambda_{h\tau} - \lambda \|_{H^{-1}(\Omega)}^2 (t) \, dt \right)^{rac{1}{2}} \right). \]

\textbf{Proof.} Denoting by \( w^* := u - z \), we have

\[ \|w^*\|_{\Omega, T}^2 \leq \int_0^T \sum_{\alpha=1}^2 \langle \partial_t (u_{a\alpha} - u_{a\alpha h\tau}), w^*_\alpha \rangle (t) \, dt + \int_0^T (\lambda_{h\tau}, w^*_1 - w^*_2)_{\Omega} (t) \, dt. \]

Next,

\[ \int_0^T (\lambda_{h\tau}, w^*_1 - w^*_2)_{\Omega} (t) \, dt = \int_0^T (\lambda_{h\tau} - \lambda, w^*_1 - w^*_2)_{\Omega} (t) \, dt + \int_0^T (\lambda, w^*_1 - w^*_2)_{\Omega} (t) \, dt. \]

Observe that

\[ \int_0^T (\lambda, w^*_1 - w^*_2)_{\Omega} (t) \, dt = \int_0^T (\lambda, u_1 - u_2)_{\Omega} (t) \, dt - \int_0^T (\lambda, z_1 - z_2)_{\Omega} (t) \, dt. \]

From (2.1) \( \lambda(u_1 - u_2) = 0 \), and as \( \lambda \in \Psi \) and \( z \in K^\gamma_g \), we have \( \int_0^T (\lambda, w^*_1 - w^*_2)_{\Omega} (t) \, dt \leq 0 \) and thus

\[ \int_0^T (\lambda_{h\tau}, w^*_1 - w^*_2)_{\Omega} (t) \, dt \leq \int_0^T (\lambda_{h\tau} - \lambda, w^*_1 - w^*_2)_{\Omega} (t) \, dt. \]

Finally,

\[ \|w^*\|_{\Omega, T}^2 \leq \int_0^T \sum_{\alpha=1}^2 \langle \partial_t (u_{a\alpha} - u_{a\alpha h\tau}), w^*_\alpha \rangle (t) \, dt + \int_0^T (\lambda_{h\tau} - \lambda, w^*_1 - w^*_2)_{\Omega} (t) \, dt. \tag{4.28}\]

Furthermore, denoting by \( A_1 \) the first term in the right-hand side of (4.28) we have,

\[ A_1 \leq \int_0^T \sum_{\alpha=1}^2 \sup_{\Phi \in H^1_0(\Omega)} \left\langle \mu_{a\alpha} \frac{1}{2} \partial_t (u_{a\alpha} - u_{a\alpha h\tau}), \mu_{a\alpha} \nabla w^*_\alpha \right\rangle_{\Omega} (t) \, dt,

\[ = \int_0^T \sum_{\alpha=1}^2 \| \mu_{a\alpha} \partial_t (u_{a\alpha} - u_{a\alpha h\tau}) \|_{H^{-1}(\Omega)}^2 \| \mu_{a\alpha} \nabla w^*_\alpha \|_{\Omega}^2 (t) \, dt. \]

The Cauchy–Schwarz inequality gives

\[ A_1 \leq \left( \int_0^T \sum_{\alpha=1}^2 \| \mu_{a\alpha} \partial_t (u_{a\alpha} - u_{a\alpha h\tau}) \|_{H^{-1}(\Omega)}^2 (t) \, dt \right)^{rac{1}{2}} \|w^*\|_{\Omega, T}. \tag{4.29}\]
To bound the second term $A_2$ of (4.28) we employ the Cauchy–Schwarz inequality

$$A_2 = \int_0^T \left( \mu_1^{-\frac{1}{2}} (\lambda_{h*} - \lambda) , \mu_2^\alpha w_t^* \right) (t) dt - \int_0^T \left( \mu_2^{-\frac{1}{2}} (\lambda_{h*} - \lambda) , \mu_2^\alpha w_t^* \right) (t) dt$$

$$\leq \int_0^T 2 \left\| \mu_a^{-\frac{1}{2}} (\lambda_{h*} - \lambda) \right\|_{\Omega^{-1}(\Omega)} \left\| \mu_a^{\frac{1}{2}} \nabla w_t^* \right\|_{\Omega} (t) dt$$

$$\leq \delta \left( \int_0^T \|\lambda_{h*} - \lambda\|_{\Omega^{-1}(\Omega)}^2 (t) dt \right)^{\frac{1}{2}} \left\| w_t^* \right\|_{\Omega; T}^2. \tag{4.30}$$

Combining (4.28), (4.29), and (4.30), we obtain the desired result. \hfill \Box

### 4.5 An a posteriori error estimate for $p \geq 1$ and each step $k \geq 1$, $i \geq 0$

In this section we devise an a posteriori error estimate which is valid at any time step $1 \leq n \leq N_t$, at any semismooth Newton step $k \geq 1$, and at any algebraic step $i \geq 0$. Several difficulties arise. Contrary to the previous case of Section 4.4, the constraints (3.15) are not satisfied because the convergence is not reached. Moreover, even if they were satisfied, the solution remains nonconforming for $p \geq 2$ because $\mathcal{K}_g^p \not\subset \mathcal{K}_g$ and $\Lambda_h^p \not\subset \Lambda$.

Consequently, we have to work with a nonconforming space-time solutions $u_h^{k,i} \not\in \mathcal{K}_g^p$ and $\lambda_{h*} \not\in \Psi$. To cope with these difficulties, we employ the decomposition

$$\lambda_{h}^{n,k,i} = \lambda_{h}^{n,k,i,\text{pos}} + \lambda_{h}^{n,k,i,\text{neg}}$$

where $\lambda_{h}^{n,k,i,\text{pos}} = \max \left\{ \lambda_{h}^{n,k,i} \right\}$ and $\lambda_{h}^{n,k,i,\text{neg}} = \min \left\{ \lambda_{h}^{n,k,i} \right\}$.

We also introduce the potential $s_h^{k,i} := \left( s_{1h}^{k,i}, s_{2h}^{k,i} \right) \in \mathcal{K}_h^p$ as a piecewise affine and continuous function in time over the whole time interval $[0,T]$, verifying $s_{1h}^{k,i}(t) - s_{2h}^{k,i}(t) \geq 0$ for all $t \in [0,T]$. When $p = 1$, a possibility is to construct $s_h^{n,k,i} := \left( s_{1h}^{n,k,i}, s_{2h}^{n,k,i} \right) \in \mathcal{K}_h^1$ by setting, for all $1 \leq n \leq N_t$ and for all $a \in \mathcal{V}_h^\text{int}$,

$$s_h^{n,k,i}(a) := \begin{cases} u_{1h}^{n,k,i}(a) = u_{1h}^{n,k,i}(a), & \text{if } (u_{1h}^{n,k,i} - u_{2h}^{n,k,i})(a) \geq 0, \\
\frac{1}{2} (u_{1h}^{n,k,i}(a) + u_{2h}^{n,k,i}(a)), & \text{if } (u_{1h}^{n,k,i} - u_{2h}^{n,k,i})(a) < 0. \end{cases} \tag{4.31}$$

**Definition 4.8.** For all $1 \leq n \leq N_t$, we define the error estimators

$$\eta_{\text{R},K,a}^{n,k,i}(t) := h_G \text{CPF} \mu_{a}^{-\frac{1}{2}} \left\| f - \partial_h s_{ah}^{n,k,i} - \nabla \sigma_{ah}^{n,k,i} - (-1)^{\alpha} \lambda_{h}^{n,k,i} \right\|_K(t),$$

$$\eta_{\text{F},K,a}^{n,k,i}(t) := \left\| \mu_{a}^{\frac{1}{2}} \nabla s_{ah}^{n,k,i} + \mu_{a}^{-\frac{1}{2}} \sigma_{ah}^{n,k,i} \right\|_K(t), \quad \eta_{\text{CF},i}^{n,k,i}(t) := 2 \left( \lambda_{h}^{n,k,i,\text{pos}}, u_{1h}^{n,k,i} - u_{2h}^{n,k,i} \right) \left( t \right),$$

$$\eta_{\text{h},k,1,K}^{n,k,i}(t) := h_G \text{CPF} \left( \frac{1}{\mu_1} + \frac{1}{\mu_2} \right)^\frac{1}{2} \left\| \lambda_{h}^{n,k,i,\text{neg}} \right\|_K(t), \quad \eta_{\text{h},k,2,K,a}^{n,k,i}(t) := \left\| \mu_{a}^{\frac{1}{2}} \nabla \left( s_{ah}^{n,k,i} - u_{ah}^{n,k,i} \right) \right\|_K(t),$$

$$\eta_{\text{h},k,3,K}^{n,k,i}(t) := 2 \left( \lambda_{h}^{n,k,i,\text{pos}}, u_{1h}^{n,k,i} - u_{2h}^{n,k,i} \right) \left( t \right), \quad \eta_{\text{h},k,4,K,a}^{n,k,i}(t) := \left\| f - \hat{f}_{a} \right\|_K(t).$$

We observe that the estimators given by Definition 4.8 are slightly different from the ones provided in Definition 4.1. Indeed, in the estimators $\eta_{\text{R},K,a}^{n,k,i}$ and $\eta_{\text{F},K,a}^{n,k,i}$, there appears a $s_{ah}^{n,k,i}$ in place of $u_{ah}^{n,k,i}$, and $\eta_{\Omega}$ instead of $h_G$. The constraint estimator $\eta_{\text{CF},i}^{n,k,i}$ is as in Definition 4.1 (remember that $\lambda_{h}^{n,k,i} \geq 0$ at convergence for $p = 1$) and expresses that $\lambda_{h}^{n,k,i} \left( s_{1h}^{n,k,i} - u_{2h}^{n,k,i} \right) = 0$ is not valid. Next, $\eta_{\text{h},k,1,K}$, $\eta_{\text{h},k,2,K,a}$, and $\eta_{\text{h},k,3,K}$ are nonconformity estimators expressing the possible negativity of the discrete Lagrange multiplier and measuring how far the potential reconstruction $s_{ah}^{n,k,i}$ is from the displacements.
Next, observe that
\[ \| u - \theta_h \|^2 = \left( \sum_{n=1}^{N_n} \int_{\Omega_n} \sum_{k \in \mathcal{K}_h} \sum_{\alpha = 1}^{2} \left( \eta_{\alpha, h}^{n,k,i} \right)^2 (t) \right) + \left( \sum_{n=1}^{N_n} \int_{\Omega_n} \sum_{k \in \mathcal{K}_h} \sum_{\alpha = 1}^{2} \left( \eta_{\alpha, h}^{n,k,i} \right)^2 (t) \right) + \left( \sum_{n=1}^{N_n} \int_{\Omega_n} \sum_{k \in \mathcal{K}_h} \sum_{\alpha = 1}^{2} \left( \eta_{\alpha, h}^{n,k,i} \right)^2 (t) \right) + \left( \sum_{n=1}^{N_n} \int_{\Omega_n} \sum_{k \in \mathcal{K}_h} \sum_{\alpha = 1}^{2} \left( \eta_{\alpha, h}^{n,k,i} \right)^2 (t) \right) + \sum_{n=1}^{N_n} \int_{\Omega_n} \sum_{k \in \mathcal{K}_h} \sum_{\alpha = 1}^{2} \left( \eta_{\alpha, h}^{n,k,i} \right)^2 (t) \right) \]

we have the a posteriori error estimate
\[ \left\| u - u_h \right\|_{\Omega, T} \leq \eta_h^{k,i} + \left( \sum_{n=1}^{N_n} \int_{\Omega_n} \sum_{k \in \mathcal{K}_h} \sum_{\alpha = 1}^{2} \left( \eta_{\alpha, h}^{n,k,i} \right)^2 (t) \right) \]

Proof. We start by the triangle inequality, leading to
\[ \left\| u - u_h \right\|_{\Omega, T} \leq \left\| u - u_h \right\|_{\Omega, T} + \left\| u_h - u \right\|_{\Omega, T} \]

The second term of (4.33) immediately equals to
\[ \left\| u - u_h \right\|^2 = \left( \sum_{n=1}^{N_n} \int_{\Omega_n} \sum_{k \in \mathcal{K}_h} \sum_{\alpha = 1}^{2} \left( \eta_{\alpha, h}^{n,k,i} \right)^2 (t) \right) \]

Next, observe that
\[ \left\| u - u_h \right\|^2 \leq \left\| u - u_h \right\|^2 + \frac{1}{2} \left\| u - u_h \right\|^2 \]

Employing the fact that
\[ \frac{1}{2} \left\| u - u_h \right\|^2 = \frac{1}{2} \left\| u - u_h \right\|^2 + \int_0^T \left( u - u_h \right)(\cdot, t) \]

we have
\[ \left\| u - u_h \right\|^2 \leq \left( \sum_{n=1}^{N_n} \int_{\Omega_n} \sum_{k \in \mathcal{K}_h} \sum_{\alpha = 1}^{2} \left( \eta_{\alpha, h}^{n,k,i} \right)^2 (t) \right) \]

We now use the weak formulation (1.2) with \( v = u_h \) and we add and subtract \( \sum_{\alpha=1}^{2} \int_0^T (\tilde{f}_\alpha, u_\alpha - \rho) \]
Adding and subtracting $\frac{2}{\alpha} \int_0^T \left(1\alpha \lambda h t, u - s_{h t}^{k, i} \right) \Omega(t) dt$ and using the Green formula with $\left( u - s_{h t}^{k, i} \right) (t) \in H^1_0(\Omega)$ a.e. $t \in [0, T]$, we obtain

$$\| u - s_{h t}^{k, i} \|_{\Omega,T}^2 \leq A_1 + A_2 + A_3 + A_4 + \frac{1}{4} \left( u - s_{h t}^{k, i} \right)(\cdot, 0) \Omega^2$$

with

$$A_1 := 2 \int_{a=1}^N \int_0^T \left( f_{\lambda} - \partial_t s_{h t}^{k, i} - \nabla \sigma_{h t}^{k, i} - (1) \alpha \lambda h t, u - s_{h t}^{k, i} \right) \Omega(t) dt,$$

$$A_2 := -2 \int_{a=1}^N \int_0^T \left( \mu_{h} + \frac{1}{\alpha} \nabla s_{h t}^{k, i}, \mu_{h} + \frac{1}{\alpha} \sigma_{h t}^{k, i}, \mu_{h} \nabla \left( u - s_{h t}^{k, i} \right) \right) \Omega(t) dt,$$

$$A_3 := 2 \int_{a=1}^N \int_0^T \left( (-1) \alpha \lambda h t, u - s_{h t}^{k, i} \right) \Omega(t) dt,$$

$$A_4 := 2 \int_{a=1}^N \int_0^T \left( f_{\lambda} - \partial_t s_{h t}^{k, i} - \nabla \sigma_{h t}^{k, i} - (1) \alpha \lambda h t, u - s_{h t}^{k, i} \right) \Omega(t) dt.$$

To bound $A_1$, $A_2$, and $A_4$ we proceed as follows. We apply the Cauchy–Schwarz inequality and next the Poincaré–Friedrichs inequality (4.16a) to get

$$A_1 \leq \left( \sum_{n=1}^N \int_{I_n} \int_{a=1}^N \sum_{K \in \mathcal{K}_h} \left( \eta_{h, K, a}^{n, k, i} \right)^2 (t) dt \right)^{\frac{1}{2}} \left\| u - s_{h t}^{n, k, i} \right\|_{\Omega,T}^2,$$

$$A_2 \leq \left( \sum_{n=1}^N \int_{I_n} \int_{a=1}^N \sum_{K \in \mathcal{K}_h} \left( \eta_{h, K, a}^{n, k, i} \right)^2 (t) dt \right)^{\frac{1}{2}} \left\| u - s_{h t}^{n, k, i} \right\|_{\Omega,T}^2,$$

$$A_4 \leq \left( \sum_{n=1}^N \int_{I_n} \int_{a=1}^N \sum_{K \in \mathcal{K}_h} \left( \eta_{h, K, a}^{n, k, i} \right)^2 (t) dt \right)^{\frac{1}{2}} \left\| u - s_{h t}^{n, k, i} \right\|_{\Omega,T}^2.$$

It remains to bound the term $A_3$. Observe that

$$A_3 = -\int_0^T b(u - s_{h t}^{k, i}, \lambda_{h t}^{k, i, neg})(t) dt - \int_0^T b(u - s_{h t}^{k, i}, \lambda_{h t}^{k, i, pos})(t) dt.$$

Next, adding and subtracting $b(u_{h t}^{k, i}, \lambda_{h t}^{k, i, pos})$ and noting that $-b(u, \lambda_{h t}^{k, i, pos}) \leq 0$ since $u \in \mathcal{K}_g$ and $\lambda_{h t}^{k, i, pos}(t) \geq 0$ for all $t \in [0, T]$, we have

$$A_3 \leq A_{31} + A_{32} + A_{33}$$

with

$$A_{31} := -\int_0^T b(u - s_{h t}^{k, i}, \lambda_{h t}^{k, i, neg})(t) dt, A_{32} := \int_0^T b(s_{h t}^{k, i} - u_{h t}^{k, i}, \lambda_{h t}^{k, i, pos})(t) dt, A_{33} := \int_0^T b(u_{h t}^{k, i}, \lambda_{h t}^{k, i, pos})(t) dt.$$
The Cauchy–Schwarz inequality and the Poincaré–Friedrichs inequality (4.16a) yield
\[
A_{31} \leq h \beta C_{PF} \left( \frac{1}{\mu_1} + \frac{1}{\mu_2} \right)^{\frac{1}{2}} \left( \sum_{n=1}^{N_t} \int_{I_n} \sum_{K \in T_n} \| \lambda_n^{k,i,\neg \neg} \|^2_K \| t \| \right)^{\frac{1}{2}} \left\| \mathbf{u} - \mathbf{s}_{h^T}^{n,k,i} \right\|_{\Omega,T}. \tag{4.40}
\]

Next, we have
\[
A_{32} = \frac{1}{2} \sum_{n=1}^{N_t} \int_{I_n} \sum_{K \in T_n} \eta_{n,k,i,\text{disc}}(t) \, dt. \tag{4.41}
\]
Furthermore, we have
\[
A_{33} = \frac{1}{2} \sum_{n=1}^{N_t} \int_{I_n} \sum_{K \in T_n} 2 \left( \lambda_n^{h,k,i,\text{pos}}, \mathbf{u}_{h^T}^{n,k,i} - \mathbf{u}_{2h^T}^{n,k,i} \right) (t) \, dt = \frac{1}{2} \sum_{n=1}^{N_t} \int_{I_n} \sum_{K \in T_n} \eta_{n,k,i,\text{pos}}(t). \tag{4.42}
\]
Finally, combining (4.35)–(4.42), employing the Young inequality \(ab \leq \frac{1}{2} (a^2 + b^2)\), \((a,b) \geq 0\), and using (4.34) provides the desired result.

\[\Box\]

5 Distinguishing the error components and adaptive stopping criteria

In Section 4.5, we have derived an a posteriori error estimate between the exact solution and approximate solution at each semismooth Newton step \(k \geq 1\) and each algebraic iterative solver step \(i \geq 0\). We now provide an a posteriori error estimate distinguishing the different error components when \(p = 1\) and define an adaptive algorithm.

5.1 Distinguishing the error components for \(p = 1\)

**Definition 5.1.** We define the total discretization error estimator \(\eta_{\text{disc}}^{k,i}\), the total semismooth linearization error estimator \(\eta_{\text{lin}}^{k,i}\), and the total algebraic error estimator \(\eta_{\text{alg}}^{k,i}\) respectively by

\[
\eta_{\text{disc}}^{k,i} := \left\{ \begin{array}{c}
3 \left( \left( \sum_{n=1}^{N_t} \int_{I_n} \sum_{K \in T_n} \sum_{\alpha=1}^{2} \eta_n^{k,i,\text{disc},\alpha} \right)^2 \right)^{\frac{1}{2}} \\
+ \left( \sum_{n=1}^{N_t} \int_{I_n} \sum_{K \in T_n} \sum_{\alpha=1}^{2} \left\| \mu_n \frac{1}{2} \nabla \mathbf{s}_{h^T}^{n,k,i} + \mu_{\alpha} \nabla \nabla \eta_{n,\text{disc},\alpha} \right\|_\Omega \right)^{\frac{3}{2}} \right) \right. \\
\left. + \left( \sum_{n=1}^{N_t} \int_{I_n} \sum_{K \in T_n} \sum_{\alpha=1}^{2} \eta_n^{k,i,\text{lin},\alpha} \right)^{\frac{1}{2}} \right),
\]

\[
\eta_{\text{lin}}^{k,i} := \left\{ \begin{array}{c}
3 \sum_{n=1}^{N_t} \int_{I_n} \sum_{K \in T_n} \left( \eta_n^{k,i,\text{lin},1} \right)^2 + \left( \sum_{n=1}^{N_t} \int_{I_n} \sum_{K \in T_n} \eta_n^{k,i,\text{lin},2} \right)^{\frac{1}{2}} \right. \\
\left. + \left( \sum_{n=1}^{N_t} \int_{I_n} \sum_{K \in T_n} \sum_{\alpha=1}^{2} \left( \eta_n^{k,i,\text{disc},\alpha} \right)^2 \right)^{\frac{1}{2}} \right),
\]

\[
\eta_{\text{alg}}^{k,i} := \left\{ \begin{array}{c}
3 \sum_{n=1}^{N_t} \int_{I_n} \sum_{K \in T_n} \sum_{\alpha=1}^{2} \left\| \mu_n \nabla \nabla \mathbf{s}_{h^T,\text{alg}}^{n,k,i} \right\|_\Omega \right) \right. \\
\left. + \left( \sum_{n=1}^{N_t} \int_{I_n} \sum_{K \in T_n} \sum_{\alpha=1}^{2} \left( \eta_n^{k,i,\text{disc},\alpha} \right)^2 \right)^{\frac{1}{2}} \right),
\]

Using Definition 5.1, we have:

**Corollary 5.2.** For \(p = 1\), we have the following a posteriori error estimate distinguishing the error components:

\[
\| \mathbf{u} - \mathbf{u}_{h^T}^{k,i} \|_{\Omega,T} \leq \eta_{\text{disc}}^{k,i} + \eta_{\text{lin}}^{k,i} + \eta_{\text{alg}}^{k,i} + \eta_{\text{init}}.
\]
Proof. The triangle inequality gives \( \eta_{K,\alpha}^{n,k,i} \leq \| \mu_{\alpha}^\frac{1}{2} \nabla s_{n,k,i}^{a,h,t} + \mu_{\alpha}^\frac{1}{2} \sigma_{a,h,t,\text{disc}}^{n,k,i} \|_K + \| \mu_{\alpha}^\frac{1}{2} \sigma_{a,h,t,\text{alg}}^{n,k,i} \|_K \). Next, using the Minkowski inequality to separate the algebraic contribution from the discretization one and employing after the result \((A_1 + A_2 + A_3)^2 \leq 3\left(A_1^2 + A_2^2 + A_3^2\right)\) for \(A_1, A_2, A_3 \geq 0\) to gather the discretization terms, we obtain the desired result. 

5.2 Adaptive inexact semismooth Newton algorithm

We finally present our adaptive inexact semismooth Newton algorithm. Following the concept of [16, 58, 55], it is designed to only perform the linearization and algebraic resolutions with minimal necessary precision, and thus to avoid unnecessary iterations. Let \( \gamma_{\text{lin}} \) and \( \gamma_{\text{alg}} \) be two positive parameters, typically of order 0.1, representing the desired relative sizes of the algebraic and linearization errors. Note that as the estimators of Definition 5.1 are global, we consider their restrictions \( \eta_{\text{disc}}^{n,k,i}, \eta_{\text{lin}}^{n,k,i}, \) and \( \eta_{\text{alg}}^{n,k,i} \) to the time interval \( I_n \) as follows:

\[
\eta_{\text{disc}}^{n,k,i} := \left( \int_{I_n} \sum_{K \in T_n} \left( \sum_{n=1}^2 \left( \left( \eta_{n,k,i}^{n,k,i} \right)^2 + \left\| \frac{1}{2} \nabla \sigma_{n,k,i}^{a,h,t} + \mu_{\alpha} \left\| \sigma_{a,h,t,\text{disc}}^{n,k,i} \right\|_K \right)^2 + \left\| \frac{1}{2} \nabla \sigma_{a,h,t,\text{alg}}^{n,k,i} \right\|_K \right)(t) \, dt \right)^\frac{1}{2}, \tag{5.1}
\]

\[
\eta_{\text{lin}}^{n,k,i} := \left( \int_{I_n} \sum_{K \in T_n} \left( 3 \left( \eta_{n,k,i}^{n,k,i} \right)^2 + \left\| \nabla \sigma_{n,k,i}^{a,h,t} \right\|_K \right)^2 (t) \, dt \right)^\frac{1}{2}, \tag{5.2}
\]

\[
\eta_{\text{alg}}^{n,k,i} := \left( 3\Delta t_n \sum_{K \in T_n} \sum_{n=1}^{2} \left\| \mu_{\alpha} \sigma_{a,h,t,\text{alg}}^{n,k,i} \right\|_K \right)^\frac{1}{2}. \tag{5.3}
\]

Let \( n \geq 1 \) be fixed. Supposing that \( \eta_{\text{init}} \) and \( \eta_{n,k,i}^{n,k,i} \) are negligible, we propose:

**Algorithm 1** Adaptive inexact semismooth Newton algorithm at each time step \( n \)

0. Choose an initial vector \( X_h^{n,0} \in \mathbb{R}^{3N_d^p,\text{int}} \) and set \( k = 1 \).

1. From \( X_h^{n,k-1} \) define \( X_h^{n,k-1} \in \mathbb{R}^{3N_d^p,\text{int}} \) and \( B^n_{k-1} \in \mathbb{R}^{3N_d^p,\text{int}} \) by (3.27).

2. Consider the linear system

\[
A_{k}^{n,k-1} X_h^{n,k} = B^n_{k-1}. \tag{5.4}
\]

3. Set \( X_h^{n,k,0} = X_h^{n,k-1} \) as initial guess for the iterative linear solver and set \( i = 0 \).

4a. Perform \( \nu \geq 1 \) steps of a chosen linear solver for (5.4), starting from \( X_h^{n,k,i} \).

   Set \( i = i + \nu \). This yields on step \( i \) an approximation \( X_h^{n,k,i} \) to \( X_h^{n,k} \) satisfying

   \[
   A_{k}^{n,k-1} X_h^{n,k,i} = B_{k-1} - R_{k,i}^{n,k,i}.
   \]

4b. Compute the estimators of (5.1)–(5.3) and check the stopping criterion for the linear solver in the form:

\[
\eta_{\text{alg}}^{n,k,i} \leq \gamma_{\text{alg}} \max \left\{ \eta_{\text{disc}}^{n,k,i}, \eta_{\text{lin}}^{n,k,i} \right\}. \tag{5.5}
\]

If satisfied, set \( X_h^{n,k} = X_h^{n,k,i} \). If not, go back to 4a.

5. Check the stopping criterion for the nonlinear solver in the form

\[
\eta_{\text{lin}}^{n,k,i} \leq \gamma_{\text{lin}} \eta_{\text{disc}}^{n,k,i}. \tag{5.6}
\]

If satisfied, return \( X_h^{n,k} = X_h^{n,k} \). If not, set \( k = k + 1 \) and go back to 1.
6 Numerical experiments

This section illustrates numerically our theoretical developments in the case of affine finite elements \( p = 1 \). We first assume that our semismooth Newton solver as well as our iterative algebraic solver have converged, \textit{i.e.}, we apply the "exact semismooth Newton" method as described in Section 3.5. In this scenario, the semismooth Newton index \( k \) and the linear iterative algebraic solver index \( i \) will be discarded. We extend to the parabolic setting the test case given in [47] in which the domain \( \Omega := \{(r, \theta) \in [0, 1] \times [0, 2\pi]\} \). We are interested in the shape of the numerical solution after several time steps and in the behavior of the estimators at convergence of the solvers given by Theorem 4.3.

Second, we will focus on our adaptive inexact semismooth Newton strategy given by Algorithm 1 of Section 5.2. For this purpose, we will consider the geometry given in the first test case with different source terms. We will test our adaptive strategy with two semismooth Newton solvers: the Newton-min solver (see (3.23)) and the Newton–Fischer–Burmeister solver (see (3.24)). The iterative algebraic solver that we employ at each semismooth Newton step \( k \geq 1 \) is GMRES (see [65, 53, 66]) with an ILU preconditioner with zero level fill-in. For each semismooth method, we compare two different approaches: the exact Newton method and the adaptive inexact Newton method. In the exact Newton case, we simulate an exact resolution in the sense that the nonlinear stopping criterion (3.30) is considered with \( \varepsilon_{\text{lin}} = 10^{-9} \) and the linear stopping criterion (3.32) is used with \( \varepsilon_{\text{alg}}^{h} = 10^{-11} \) for all Newton iterations \( k \). For the adaptive inexact semismooth Newton strategy, we consider the stopping criteria (5.5) and (5.6) with \( \gamma_{\text{lin}} = \gamma_{\text{alg}} = 10^{-3} \).

For these two studies, the parameters \( \mu_{1} \) and \( \mu_{2} \) are set to 1 and the boundary condition for the first unknown \( g \) is equal to 0.05. We consider a mesh containing approximately 21,000 elements. For the sake of simplicity, we consider a constant time step \( \Delta t = \Delta t = 0.001 \) for all \( 1 \leq n \leq N_{t} = 300 \) and the final time of simulation \( t_{F} = 0.3 \). The initial guess \( X_{h}^{0} \in \mathbb{R}^{2N_{h}^{\text{ext}}} \) has its first \( N_{h}^{\text{ext}} \) components equal to \( g \) and its next components equal to zero.

6.1 Exact semismooth Newton method

Following [47], we take

\[
\begin{align*}
    f_{1}(r, \theta, t) &:= \begin{cases} 
        -10g & \text{if } r \leq 1/\sqrt{2}, \\
        -8g & \text{if } r \geq 1/\sqrt{2}, 
    \end{cases} \\
    f_{2}(r, \theta, t) &:= \begin{cases} 
        -6g & \text{if } r \leq 1/\sqrt{2}, \\
        -g \frac{1 + 8r - 18r^{2}}{r} \sqrt{2} & \text{if } r \geq 1/\sqrt{2}. 
    \end{cases}
\end{align*}
\]

In this case, \( f_{0}\hat{I}_{x} = f_{0}^{a} \), so the data oscillation estimator \( \eta_{\text{osc},a}^{n} \) is zero.

Figure 1 displays for three time values \( t = 0.02, t = 0.17, \) and \( t = 0.3 \) the behavior of the numerical solution \( (u_{1h}^{n}, u_{2h}^{n}, \lambda_{h}^{n}) \), as well as the behavior of the constraint estimator \( \eta_{C,K}^{n} \). In the first situation, corresponding to the beginning of the simulation \( t = 0.02 \) (see the top of Figure 1), the complementarity constraint \( u_{1h}^{n} - \lambda_{h}^{n} > 0 \) is satisfied, and then the discrete Lagrange multiplier \( \lambda_{h}^{n} \) as well as the constraint estimator \( \eta_{C,K}^{n} \) vanish. Next, we represent the numerical solution at the time value \( t = 0.17 \) where \( u_{1h}^{n} \) and \( u_{2h}^{n} \) coincide in a subset of \( \Omega \). The constraint estimator detects at each time step the elements where \( u_{1h}^{n} \) and \( u_{2h}^{n} \) become in contact (or detach from one another). Finally, at the end of the simulation \( t = 0.3 \), see the bottom of Figure 1, the discrete Lagrange multiplier \( \lambda_{h}^{n} \) is positive in the whole area \( r \leq 1/\sqrt{2} \), recovering the numerical result of the stationary case [47]. We note that the constraint estimator \( \eta_{C,K}^{n} \) take very small values.

Figure 2 displays the behavior of the flux estimator \( \eta^{n}_{F,K,2} \) and of the residual estimator \( \eta_{R,K,2}^{n} \) (see Theorem 4.3) associated to the second discrete unknown \( u_{2h}^{n} \) at the final simulation time \( t = 0.3 \). We observe that the residual estimator \( \eta_{R,K,2}^{n} \) is small with respect to the flux estimator \( \eta_{F,K,2}^{n} \). Furthermore, in several elements \( K \in T_{h} \), the estimator \( \eta_{F,K,2}^{n} \) is quite large which corresponds to zones where the finite element discretization error is important.
Figure 1: Numerical solution and constraint estimators at convergence for approximately 21000 elements. First column: approximations $u_{1h}^n$ and $u_{2h}^n$, second column: Lagrange multipliers $\lambda^n_h$, third column: constraint estimators; all respectively at times $t = 0.02$, $t = 0.17$, and $t = 0.3$.

Figure 2: Estimators at convergence for approximately 21000 elements at $t = 0.3$. Left: flux estimator $\eta^{n}_{F,K.2}$. Right: residual estimator $\eta^{n}_{R,K.2}$.
6.2 Adaptive inexact algorithms

The domain \( \Omega \) is here still the unit disk but we consider the data \( f_1 \) and \( f_2 \) given by

\[
\begin{align*}
  f_1(r, \theta, t) &:= \\
  &\begin{cases} 
-20g & \text{if } r \leq 1/5, \\
-50g & \text{if } 1/5 \leq r \leq 2/5, \\
+50g & \text{if } 2/5 \leq r \leq 3/5, \\
-50g & \text{if } 3/5 \leq r \leq 4/5, \\
+50g & \text{if } 4/5 \leq r \leq 1,
\end{cases} \\
  f_2(r, \theta, t) &:= \\
  &\begin{cases} 
+90g & \text{if } r \leq 1/5, \\
-40g & \text{if } 1/5 \leq r \leq 2/5, \\
+70g & \text{if } 2/5 \leq r \leq 3/5, \\
-30g & \text{if } 3/5 \leq r \leq 4/5, \\
+40g & \text{if } 4/5 \leq r \leq 1.
\end{cases}
\end{align*}
\]

Here again \( \eta_{osc,\alpha} \) vanish.

First of all, we display for several time steps the behavior of the numerical solution. Next, for a fixed time value, we represent the estimators as a function of the Newton iterations. Furthermore, for one selected Newton iteration, we also present the evolution of the various estimators as a function of the GMRES iterations. Finally, we test for each adaptive inexact semismooth Newton solver its overall performance and we compare the results with the classical exact resolution.

Figure 3 displays the numerical solution at three time values when the Newton-min solver and GMRES solver have converged. There are three different phases in the simulation: at first, there is no contact, see the left column of Figure 3. In the second period, the contact occurs in a disk around the center of the domain and we observe in the discrete Lagrange multiplier \( \lambda_n^h \) a peak indicating the elements where \( u_{1h}^n \) and \( u_{2h}^n \) coincide. In the last period (top right and bottom right of Figure 3), there exist two separate contact zones, a disk for \( 0 \leq r \leq 1/5 \) and a ring for \( 2/5 \leq r \leq 3/5 \). Furthermore, these contacts occur at \( t \approx 0.011 \) and \( t \approx 0.060 \); we will see below in Figures 5 and 8 (left) that more Newton-min iterations will be required at these transition periods.

6.2.1 Newton-min linearization

Figure 4 presents the evolution of the various estimators as a function of the Newton-min iterations (left) and the behavior of the various estimators as a function of the GMRES iterations at the first Newton-min step (right) at the fixed time value \( t = 0.084 \). From the left part of Figure 4, we observe that the discretization estimator globally dominates and coincides with the total estimator (the two curves are roughly superimposed). The linearization estimator (blue curve) is small from the first Newton-min iteration (around \( 10^{-6} \)) and next increases at the second iteration (around \( 10^{-3} \)) and afterwards decreases
Figure 4: At $t = 0.084$. Left: estimators as a function of the Newton-min iterations. Right: estimators as a function of the GMRES iterations on 1st Newton-min iteration.

Figure 5: Left: number of Newton-min iterations at each time step. Right: cumulated number of Newton-min iterations as a function of time.

rapidly to reach the value $10^{-11}$ at the third Newton-min iteration. From the first Newton-min iteration, the discretization estimator (coinciding with the total estimator) stagnates which means that the other components of the error do not influence the behavior of the total error estimator. Then, the Newton-min algorithm performs unnecessary iterations and can be stopped at the first iteration. In right part of Figure 4, we test our adaptive inexact Newton-min strategy in terms of the GMRES iterations for the first Newton-min iteration. We observe that the discretization estimator as well as the linearization estimator roughly stagnate after few iterations. The algebraic estimator is large at the beginning of the iterations and influences the behavior of the total estimator but decreases rapidly to reach at $i = 53$ the value $10^{-12}$. The adaptive inexact Newton-min algorithm stops the GMRES after $i = 24$ iterations, when the total estimator almost coincides with the discretization estimator. Note that the curve of the algebraic estimator is here close to the curve of the algebraic residual.

Figure 5 provides the number of Newton-min iterations and the cumulated number of Newton-min iterations required to satisfy the given stopping criteria at each time step of the simulation. In particular, the first graph shows that for almost all time steps, our adaptive strategy is cheaper in terms of Newton-min iterations than the exact resolution. Observe that at some (rare) time steps (13 and 57 for instance), the adaptive approach requires more iterations than the classical resolution: it detects automatically when a few more iterations are necessary to preserve the accuracy. Interestingly, this occurs at times when $u_{1h}^n$ and $u_{2h}^n$ enter in contact. The second graph presents the cumulated number of Newton-min iterations as a function of time.
Figure 6: Left: number of GMRES iterations per time and Newton-min steps. Right: cumulated number of GMRES iterations as a function of time.

Table 1: Accuracy of the adaptive inexact Newton-min solution for several time values.

function of the time step. We observe a substantial benefit for our adaptive inexact Newton-min approach as it saves at the end of the simulation roughly 50% of the iterations.

In Figure 6, left, we plot the number of GMRES iterations per time and Newton-min steps, between time steps 22 and 72. We can observe that significantly fewer iterations are needed in the adaptive approach. We illustrate the overall performance of the two approaches in Figure 6, right, where we display the cumulated number of GMRES iterations for the two methods as a function of the time steps. The second graph shows that the adaptive inexact Newton-min algorithm requires approximately 7000 cumulated iterations to converge whereas the classical algorithm requires roughly 19000 iterations. Our adaptive algorithm thus saves many unnecessary iterations.

In Table 1, we give the global energy norm of the difference between the approximate resolution given by the exact solution and the approximate solution provided by the adaptive inexact Newton-min algorithm. We observe that for several time values, the three numerical solutions are close to each other, which confirms that our adaptive strategy does not violate the accuracy of the numerical solution.

6.2.2 Newton–Fischer–Burmeister linearization

In this part, we proceed as in Section 6.2.1 employing this time the C-function of Fischer–Burmeister.

Figure 7 represents the evolution of the various estimators as a function of the Newton–Fischer–Burmeister iterations (left) and the behavior of the various estimators as a function of the GMRES iterations at the first Newton–Fischer–Burmeister step (right), at the fixed time value $t = 0.011$. From the left plot, we observe that the discretization estimator globally dominates and almost coincides with the total estimator (the two curves are roughly superimposed). The linearization estimator (blue curve, squares) is small and decreases rapidly after $k = 5$ steps (adaptive stopping criterion) to reach the value of $10^{-11}$ at $k = 11$ (classical stopping criterion). Taking $\gamma_{\text{lin}} = 10^{-2}$ instead of $\gamma_{\text{lin}} = 10^{-3}$ in (5.6) will reduce the number of Newton–Fischer–Burmeister iterations at this instant to 4. In the right plot, we take the first Newton–Fischer–Burmeister iteration and we observe that the discretization estimator as well as the linearization estimator stagnate from the beginning of the iterations, while the algebraic estimator is dominant at the
Figure 7: At $t = 0.11$. Left: estimators as a function of the Newton–Fischer–Burmeister iterations. Right: estimators as a function of the GMRES iterations at the first Newton–Fischer–Burmeister step.

beginning of the iterations. The adaptive inexact Newton–Fischer–Burmeister algorithm stops the GMRES iterations at $i = 9$, whereas the classical criterion stops at $i = 33$. Note that as for the Newton-min case, the behavior of the algebraic estimator follows here closely the one of the algebraic residual.

Figure 8 focuses on the number of Newton–Fischer–Burmeister iterations required to satisfy the various stopping criteria at each time step. We observe from the first figure that the adaptive strategy (red curve) is economic in comparison with the classical resolution (blue curve) especially from $t = 0.1$ onwards, where the adaptive algorithm requires 1 Newton–Fischer–Burmeister iteration at each time step. Furthermore, the right plot depicts the overall performance in terms of Newton–Fischer–Burmeister iterations. With no surprise, the adaptive resolution requires at the end of the simulation much fewer semismooth Newton iterations (approximately 700 for the adaptive algorithm and 1500 for the classical resolution). Thus, our adaptive semismooth approach reduces by 50% the number of Newton–Fischer–Burmeister iterations.

Figure 9 illustrates the overall performance of the two approaches. We display the number of GMRES iterations for each linear system solved as a function of time/Newton–Fischer–Burmeister step between $t = 0.014$ and $t = 0.057$ (left) and the cumulated number of GMRES iterations as a function of time step (right). In particular, we see that our adaptive strategy is very economic in terms of the total algebraic iterations as it requires at the end on the simulation approximately 7000 iterations whereas the classical resolution requires roughly 27 000 iterations. To close this section, we present in Table 2 the energy norm of
Figure 9: Left: number of GMRES iterations per time and Newton–Fischer–Burmeister step. Right: cumulated number of GMRES iterations per time step.

7 Conclusion

In this work, we focused on deriving a posteriori error estimates for a model parabolic variational inequality. We employed the conforming \( P_p \) finite element method for the discretization in space and the backward Euler scheme for the discretization in time. We designed a posteriori error estimates when \( p = 1 \) valid at convergence of the semismooth Newton solver and of the iterative algebraic solver. In this case, we estimate both energy and time derivative errors. Next, we extended the study to all polynomial degrees \( p \geq 1 \) and for each semismooth Newton step \( k \geq 1 \) and each iterative linear algebraic solver step \( i \geq 0 \). Here, we only estimate the energy error. We finally proposed an adaptive inexact semismooth Newton algorithm based on the a posteriori error estimators that we derived whose main idea is to stop the two involved iterative solvers at a suitable moment decided adaptively. We have presented numerical experiments for two inexact semismooth Newton solvers for \( p = 1 \) and we showed that our adaptive inexact semismooth strategy saves many iterations while preserving the accuracy of the numerical solution.
