2-D Analytical Model of Conventional Switched Reluctance Machines

Walid Belguerras Youcef Benmessaoud Frédéric Dubas Kamel Boughrara Mickael Hilaiet

Abstract In this paper, we present a two-dimensional (2-D) analytical model of a conventional switched reluctance machines (SRMs). This model has been applied to a 8/6 conventional SRM supplied by conventional excitation (viz., standard asymmetric H-bridge). The goal is to determine the electromagnetic performances. The proposed analytical model is based on solving the partial differential equations (PDEs) due to Maxwell's equations in each domain of the studied machine (viz., air-gap, rotor and stator slots). A parametric study by using the developed analytical model has been compared with that obtained by numerical computations in linear and no-linear conditions. The results showed that the analytical and numerical results are in good agreements in linear conditions. However, in no-linear conditions, the developed model over-estimates the performances. Indeed, to pre-design the machine, this model can be incorporated in optimization environments where savings in computation time are needed.

1 Introduction

The SRMs present many benefits for high-speed applications (e.g., electric compressor) compared with other types of machines. It can be operated at a very high-speed because it has no sliding contacts [1, 2], and can be operate in sever conditions of temperatures. It is a competitor of a permanent-magnet synchronous machines for electric vehicle

applications because of its simplicity and low cost, and its ability to operate at high-speed with low maintenance [3-5]. In the literature, we find different methods of electromagnetic modeling of electric machines; semi-analytical modeling based on the magnetic equivalent circuit (or permeance network) [6, 7], subdomain method in linear conditions (i.e., infinite permeability of the iron parts) [8-10], and the exact subdomain method taken into account the iron permeability [11-15]. In addition, we find analytical methods based on multi-layers [16-19] or elementary subdomains for the local saturation effect [20-21].

The analytical methods cited previously give an accurate electromagnetic result compared with numerical calculations, with reduced computation time. In this paper, we will present a comparison study of 2-D electromagnetic performances between the developed linear model based on the subdomain method in linear conditions. In order to analyse the validity of the developed model, the results has been compared with those computed numerically using FEMM [22] in linear and no-linear conditions.

2 Analytical model

The analytical model based on the subdomain method in linear conditions is given in [8-10]. In order to simplify the model, we have considered the following assumptions:

- End-effects are neglected, i.e., $\mathbf{A} = \{0; 0; A_z\}$;
- Eddy-currents effects in all materials are neglected;
- Current density in the stator slots has only on component along the z-axis, i.e., $\mathbf{J} = \{0; 0; J_z\}$;
- The slots have a radial sides;
- The relative permeability is considered infinite for the iron parts (i.e., the saturation effect is neglected).

The schematic representation of the studied 8/6 conventional SRM is shown in Fig. 1.

In developing the 2D analytical model, a magnetic vector potential formulation is used in polar coordinates. It consists of solving the partial differential equation [23] due to

Fig. 1 Example of 8/6 conventional SRM.

Table 1 Parameters of 8/6 conventional SRM

Parameter	Value
Q_s Number of stator slots	8
Q_r Number of rotor slots	6
R_{sh} Radius of the shaft	11.5 mm
R_{ry} Radius of the rotor yoke	20.9 mm
R_r Radius of the rotor surface	33.9 mm
R_s The stator bore radius	43 mm
R_{sy} Radius of the stator yoke	53.4 mm
R_{out} Outer radius of the stator	71.5 mm
L Axial length	125 mm
θ_{sso} Stator slot opening	25.2°
θ_w Opening of a slot coil	12.6°
θ_{ts} Stator teeth opening	19.8°
θ_{rso} Rotor slot opening	39.3°
θ_{tr} Rotor teeth opening	20.6°
N Number of harmonic in air-gap	150
M Number of harmonic in rotor slots	150
K Number of harmonic in stator slots	150
P Pitch used in calculation	12°

Maxwell's equations in each domain of the studied machine. The equations to be solved in each region are given by

$$\frac{\partial^2 A_{zI}}{\partial r^2} + \frac{1}{r} \cdot \frac{\partial A_{zI}}{\partial r} + \frac{1}{r^2} \cdot \frac{\partial^2 A_{zI}}{\partial \theta^2} = 0 \quad (\text{Region } I), \quad (1a)$$

$$\frac{\partial^2 A_{zj}}{\partial r^2} + \frac{1}{r} \cdot \frac{\partial A_{zj}}{\partial r} + \frac{1}{r^2} \cdot \frac{\partial^2 A_{zj}}{\partial \theta^2} = 0 \quad (\text{Region } j^{th}). \quad (1b)$$

$$\frac{\partial^2 A_{zi}}{\partial r^2} + \frac{1}{r} \cdot \frac{\partial A_{zi}}{\partial r} + \frac{1}{r^2} \cdot \frac{\partial^2 A_{zi}}{\partial \theta^2} = -\mu_0 \cdot J_{zi} \quad (\text{Region } i^{th}). \quad (1c)$$

Solving of PDEs given by (1) allows to obtain the general solution of A_z in each domain [8-10]. The integration constants are determined by using a Fourier series expansion of A_z in each region and the boundary conditions (BCs) [8-21]. The linear system can be written as

$$[A] \cdot [X] = [B], \quad (2)$$

where:

- $[A]$ is the square matrix of the integration constants obtained by BCs of dimension $Q \times Q$ with $Q = 4N + Q_r \cdot (1 + M) + Q_s \cdot (1 + K)$ in which Q_s & Q_r represents respectively number of the stator and rotor slots, and N , M & K represents respectively the finite number of spatial harmonics terms in various regions;
- $[X]$ is the vector of unknowns (integration constants to determine) with dimension $Q \times 1$;
- $[B]$ is the vector of electromagnetic sources terms with dimension $Q \times 1$.

The vector $[X]$ can be divided in 3 parts as following:

- Part 1 is air-gap (i.e., Region I) with dimension $4N \times 1$;
- Part 2 is the rotor slots (i.e., Region j^{th}) with dimension $Q_r \cdot (1 + M) \times 1$;
- Part 3 is the stator slots (i.e., Region i^{th}) with dimension $Q_s \cdot (1 + K) \times 1$.

Using the geometrical and physical parameters given in Table 1, we have calculated the computing time necessary for obtaining the vector $[X]$ (viz., $t=58.85$ s for 31 position), and the computing time necessary for making the mesh and analyse on FEMM (viz., $t=151.33$ s for 31 positions. The auto-mesh is used).

3 Simulation results

The analytical expression of electromagnetic torque and the method for calculating the flux are given in [9, 10, 13-21]. We have used the parameters of SRM given in [24] for our comparison study.

Fig. 2 shows the equipotential lines of A_z in the machine due to phase A ($I_A=20$ A) at 180° rotor position obtained by numerical model. Fig. 3 shows the radial and tangential magnetic flux density in the middle of the air-gap by feeding only phase A ($I=10$ A) for rotor position 45° .

Fig. 2 Equipotential lines of A_z due to phase A for $I_A=20$ A and 180° rotor position.

Fig. 3 Radial (a) and tangential (b) components of magnetic flux density in the air-gap for $I_A=10$ A and rotor position 45° .

Fig. 4 Waveform of flux per phase due to phase A.

Fig. 4 shows a comparison between the numerical and analytical result of flux per phase due to phase A. In linear ($I=10$ A), the numerical and analytical results are in well agreement. In no-linear, the relative error between analytical and numerical results is 46.56 %. The mutual flux between phase A and others phases is shown in Fig. 5. In no-linear, the analytical and numerical results present the 49.12 % relative error. The mutual flux between phases A-C is null because the opening between this phases is $\pi/2$.

Fig. 6 shows the comparison between analytical and numerical results of static electromagnetic torque due to phase A. It can be seen that the analytical model gives the accurate results in linear. In no-linear, we have a 42.15 % relative error between the analytical and numerical results. This important relative error due to no considering the relative permeability of iron parts in the analytical model.

Fig. 5 Waveform of mutual flux obtained by feeding phase A in: (a) linear ($I_A=10$ A), and (b) no-linear ($I_A=50$ A).

Fig. 6 Waveform of the static electromagnetic torque due to phase A in: (a) linear ($I_A=10$ A), and (b) no-linear ($I_A=50$ A).

Fig. 7 The maximum electromagnetic torque due to phase A for different values of current.

Fig. 8 The maximum self-inductance due to phase A for different values of current.

Fig. 7 shows the comparison between analytical model and (no-)linear numerical results of the maximum electromagnetic torque due to phase A for different values of current (0-100 A). The results of the max self-inductance due to phase A for different values of current (0-100 A) obtained by analytical model, and (no-)linear numerical model are shown in Fig. 8. It can be seen that the analytical model gives a good results with no-linear numerical result in limited current rang ($I \leq 30$ A for max torque, and $I \leq 20$ A for max self-inductance).

4 Conclusion

In this paper, we have presented an analytical model based on the subdomain method of 8/6 conventional SRM in linear conditions. The analytical results are in excellent agreement with numerical ones. However, in no-linear conditions ($I=50$ A), the developed model overestimates the electromagnetic performances with a maximum error of about 46 %. However, by taking into account this error, this model can be usefully used in optimization procedure where saving of computation time is required. In order to obtain more accurate performances in no-linear conditions, this model can be extended to the saturation case (taking into account the characteristic of relative permeability of iron parts). It will be the object of our future works.
