Robotic manipulation planning for shaping deformable linear objects with environmental contacts

Jihong Zhu, Benjamin Navarro, Robin Passama, Philippe Fraisse, André Crosnier and Andrea Cherubini

Abstract—Humans use contacts in the environment to modify the shape of deformable objects. Yet, few papers have studied the use of contacts in robotic manipulation. In this paper, we investigate the problem of robotic manipulation of cables with environmental contacts. Instead of avoiding contacts, we propose a framework that allows the robot to use them for shaping the cable. We introduce an index to quantify the contact mobility of a cable with a circular contact. Based on this index, we present a planner to plan robot motions. The planner is aided by a vision-based contact detector. The framework is validated with robot experiments on different desired cable configurations.

Index Terms—Dexterous Manipulation, Contact Modeling, Manipulation Planning

I. INTRODUCTION

Humans are able to manipulate objects with high dexterity. For decades, we have been trying to give robots similar capabilities. Robotic manipulation has been studied intensively with the focus on rigid objects. However, humans encounter all kinds of deformable objects and manipulate them on a regular basis. Therefore, to fully embed robots with human-like manipulation skills, we should pay considerable attention to deformable objects manipulation. The fields of application include areas like surgical operation, agriculture, food making, household services and industrial automation.

One of the biggest challenges in deformable objects manipulation is the infinite degree of freedoms in the object deformation versus finite inputs from robot manipulators/hands. Often, when dealing with deformable objects, humans not only apply both hands, but also use contacts in the environment to regulate the object shape. For instance, when folding a towel, we place it on a flat surface to constrain its deformation due to gravity.

Deformable objects with linear shapes such as cables, wires, etc., are often referred to as deformable linear objects (DLOs) in the literature. Yet, for simplicity, we will denote them as cables in this paper. In cable harness, cables need to follow a designated path defined by a set of contacts. Our objective is to establish a robotic manipulation framework that automates the cable routing process.

We simplify this problem by considering circular contacts on the board. The robot plans its motion according to the contacts placement, detects the occurrence of a contact, modifies its manipulation behaviour accordingly and finally achieves a desired configuration of the cable.

A. Related work

We outline works that have been done in robotic cable manipulation in three sub-categories: cable modelling, manipulation planning and shape control.

In manipulation planning, contact with the environment is often considered as undesired – and thus to be avoided. A collision free path planner was developed in [8] using a randomized algorithm. A planner in [9] computed a path in the shape space from one minimal energy curve to another while satisfying environmental constraints. Bretl and McCarthy showed that the shape space of an elastic rod is a six-dimensional smooth manifold [10]. Later, the authors of [11] took a step forward and proved the path-connectedness of this space.

In shape control, we distinguish model-based and model-free methods. Nakagaki et al. used a deformation model for
insertion tasks [12]. Navarro-Alarcon et al. developed a model-free Fourier-based shape servoing strategy [13]. We extended that work to the shape servoing of cables in [14].

Few papers have investigated cable manipulation with contacts in the environment. In a pioneer work [15], the authors presented the specification of contact states for linear objects with polyhedral obstacles, and identified unstable/stable contact states. Acker and Henrich further proposed visual features for the detection of contact state transitions in cable manipulation [16]. In a more recent research [17], the authors planned cable manipulation strategies with a simulator in both free and contact space. Some works in deformable object manipulation exploited contact for manipulation; plastic material shaping [18] and towel folding [19] where some or all manipulation tasks were done with contact compensating the gravity. Yet, these papers do not study the specific use of contact.

B. Our contribution

To the best of authors’ knowledge, contact-based cable routing relying on robotic manipulation is still an open research problem. Yet, it is widely present in the industry (e.g., in cable harness). We address this practical problem by a mathematical analysis on the contact mobility. We propose an index to quantify the mobility. This index motivates our choice of motion primitives. A motion planning framework using the primitives is designed for the robot to shape a cable by contacts. The performance of the framework is analyzed using the proposed contact mobility index.

C. Paper organization and notation

The paper is organized as follow. Sec. II states the contact-based cable manipulation problem and presents an overview of the framework. Sec. III defines the angular contact mobility index. Then we analyze two cable motions and their effect on the index. Sec. IV proposes motion primitives for the robot. Sec. V presents the planner which uses the motion primitives for planning robot motions. Sec. VII explains the setup and shows experiment results 1. In the last section, we conclude and propose some future research directions.

We employ the following mathematical notation throughout the paper. Vectors are denoted with small bold letters, e.g. \( \mathbf{v}, \mathbf{w} \). Matrices are with capital bold letters e.g. \( \mathbf{A}, \mathbf{B} \). The vector difference is denoted by \( \rightarrow \), e.g. \( \vec{\mathbf{w}} = \mathbf{w} - \mathbf{v} \). The Euclidean norm of a vector is given by \( || \cdot || \), e.g. \( ||\mathbf{v}||, ||\vec{\mathbf{w}}|| \).

II. PROBLEM STATEMENT AND FRAMEWORK OVERVIEW

A. Problem statement

The overall problem is depicted in Fig. 2. We consider contacts as small circles on the 2D plane. For a cable with sufficient length, given a starting end of the cable, with a list of ordered small \(^2\) circular contacts placed on the plane, the cable should be manipulated such that it follows the path defined by the contacts’ position and sequence. The order of the contacts is known a priori by the robot. The cable must be shaped by each contact sequentially and in the end reach the target position.

![Fig. 2. A contact-based manipulation example to illustrate the problem. The order of the contacts is given by the number besides each contact. This information is provided a priori to the robot.](https://youtu.be/7CdNQ4R_wT0)

The cable should touch all contacts in the given order, without creating any loop. We do not consider friction in this work, and neglect the cable’s deformation along the tangential direction.

B. Framework overview

We utilize a dual arm robot for the cable manipulation task. The robot is equipped with two end-effectors \( \mathcal{M} \) and \( \mathcal{F} \). We place \( \mathcal{F} \) at a fixed pose to hold the starting end of the cable. \( \mathcal{M} \) holds the other end of the cable and is free to move on the 2D manipulation plane. An in-hand camera is mounted on \( \mathcal{M} \) to provide visual feedback.

The framework consists of a planner and a vision-based contact detector. The planner plans the motion for \( \mathcal{M} \) given contacts and a target location. The detector identifies the occurrence of a contact.

III. ANGULAR CONTACT MOBILITY INDEX

One way of analyzing the contact is by its mobility index, which measures the free motion of the object in contact [20]. In this section, we introduce a novel contact mobility index based on the angular range of motion. We term it Angular Contact Mobility Index (ACMI). The robot manipulates the cable on a plane. The cable is soft and can adapt to the curvature of the contact object. In Fig. 3 we show an example. We construct a local Cartesian coordinate frame \( O_{xy} \) at the center of the object. We consider the motion of the cable relative to the contact. The direction of motion is a unit vector \( \mathbf{v}(\phi) = [\cos \phi \ \sin \phi]^T \) with \( \phi (0 \leq \phi < 2\pi) \) the angle between the vector and \( x \) axis. For any point \( \rho \) on the contact curve, the direction of the contact force is denoted \( \mathbf{n}(\rho) \).

![Fig. 3. Example of a circular object in contact with a cable. The green vector is a candidate direction of relative object/cable motion. Many others directions are possible.](https://youtu.be/7CdNQ4R_wT0)

\(^1\)The video of the experiments can be found at: https://youtu.be/7CdNQ4R_wT0

\(^2\)The radius of the contact is much smaller than the length of the cable.
Definition 1. Angular Contact Mobility Index (ACMI): the angle (in radians) that represents the range of directions the object can move to break free from the contact.

In Fig. 4, we consider four cases: the direction of motion of the contact object (red circle) with regards to the cable. The direction \( \mathbf{v} \) is parameterized by \( \phi \). We derive the ACMI for these cases and finally provide a general expression of the ACMI.

When there is no contact (Fig. 4a), the break free (from contact) directions are given by the following set:

\[
\mathcal{R} = \{ \phi \in [0, 2\pi] \}.
\]

Since the object can move in all directions, the ACMI equals \( 2\pi \).

For a single contact point \( \rho \) (Fig. 4b), the set of break free directions is defined by:

\[
\mathcal{R}(\rho) = \{ \phi \in [0, 2\pi] : \mathbf{n}(\rho) \cdot \mathbf{v}(\phi) > 0 \}.
\]

This defines an open set of directions with only positive \( \mathcal{R}(\rho) \) is \( \pi \). The ACMI equals \( \pi \).

For the curved contact in Fig. 4c, the set of break free directions is expressed by:

\[
\mathcal{R} = \bigcap_{\rho = \rho_1}^{\rho_2} \mathcal{R}(\rho).
\]

Noting \( \psi \) the contact curve angular range, if \( \psi \in [0, \pi] \), then the ACMI is \( \pi - \psi \).

Instead, if \( \psi \in (\pi, 2\pi] \) (see Fig. 4d), the ACMI equals 0. No matter which direction the object moves, it cannot break free from the contact.

To sum up, we provide a quantitative definition of the ACMI:

\[
\text{ACMI} = \begin{cases} 
2\pi, & \text{No contact}, \\
\pi, & \text{Point contact}, \\
\max(0, \pi - \psi), & \text{Curved contact}.
\end{cases}
\]

Using the ACMI, we quantify the free motion range due to the contact. The higher the index, the larger the range of motion sufficient to break free from contact (i.e., it is easier to lose contact).

Below we analyze two motions of the cable and their effects.

The first motion is termed rotation. Starting from an initial contact point \( \rho_2 \) scenario depicted in Fig. 5, the ACMI is \( \pi \). Consider the left segment of the cable fixed, and perform an anti-clockwise rotation with center at the contact for the right segment: we expect the contact point to become a curve. Then the length of the curve grows due to this movement, so the ACMI decreases. The reverse motion will make the contact curve shrink, and the ACMI increase.

\[
\begin{array}{c}
\text{final} \\
\rho_2 \\
\text{Contact}
\end{array}
\]

Fig. 5. The effect of rotation on the ACMI.

The second motion is termed sliding. In case of contact point (Fig. 6a), sliding corresponds to:

\[
\mathcal{R}(\rho) = \{ \phi \in [0, 2\pi] : \mathbf{n}(\rho) \cdot \mathbf{v}(\phi) = 0 \}.
\]

For a curved contact with two end points (Fig. 6b), we denote two edges of the curve as \( \rho_1 \) and \( \rho_2 \) with \( \mathbf{n}_1 \) and \( \mathbf{n}_2 \) being the directions of the associated contact force. Sliding corresponds to the direction within:

\[
\mathcal{R}_1 \cup \mathcal{R}_2,
\]

with

\[
\begin{align*}
\mathcal{R}_1 &= \{ \phi \in [0, 2\pi] : \mathbf{n}_1 \cdot \mathbf{v}(\phi) = 0 \}, \\
\mathcal{R}_2 &= \{ \phi \in [0, 2\pi] : \mathbf{n}_2 \cdot \mathbf{v}(\phi) = 0 \}.
\end{align*}
\]

In both figures we show an example of contact after sliding in a specific direction. The sliding motion maintains the contact curve (point) and the ACMI stays unchanged.

Fig. 6. The effect of sliding on the ACMI.

In the next sections, we will relate robotic cable manipulation with these two motions. Using the ACMI, we show in Sec. VII-C that with the proposed framework, the robot constructs and utilizes contacts for shaping the cable to reach a desired configuration.
pull the cable so that the length of the cable between the two end-effectors increases (Fig. 7b).

We define two motion primitives for the dual arm robot to accomplish the task:

- **rotate**: \( F \) hold + \( M \) rotate.
- **pull**: \( F \) release + \( M \) pull.

### V. Planner

In this section, we introduce planners for the robot motion. For each contact, the robot executes the pull motion primitive to reach an initial pose for making contact and then the rotate motion primitive to construct and use the contact. Since the cable length is much larger than the contact radius, the radius is assumed neglectable in the section.

The flow chart describing the overall motion generated by the planner for \( n \) ordered contacts is shown in Fig. 8.

#### A. Initial pose planner

The initial pose planner plans a discrete target pose \( q_M \) around each contact. We denoted the planned pose as \( q^* = [p^* T \theta^*]^T \), with \( p^* = [x_p^* \ y_p^*]^T \) as position and \( \theta^* \) as orientation.

Let us consider a general case in Fig. 9. We set the fixed point on the cable at \( f = [x_f \ y_f]^T \), the current contact at \( c = [x_c \ y_c]^T \), the next contact at \( r = [x_r \ y_r]^T \). The fixed point is either at origin of \( Fxy \) or the previous contact location which regulates the cable. We use pull to reach each target planned pose.

After having reached the planned pose we rotate with the center at \( f \) to construct a contact, so the cable length is fixed. Thus, we have our first condition on \( p^* \):

\[
\left\{ p^* \in \mathbb{R}^2 \mid |||fp^*||| > |||fe||| \right\}.
\]

Otherwise, the cable cannot reach the contact by rotation.

We separate the plane into two half planes, by a line connecting the fixed point \( f \) and the contact \( c \). We denote the half plane with the next contact as \( P \) and the other one as \( P' \). To reach the next contact, we need:

\[
p^* \in P'.
\]

We envision \( M \) to be near the contact, because if it is far, more effort is needed to bring the cable in contact. To this end, we impose a third condition:

\[
\left\{ p^* \in \mathbb{R}^2 \mid |||cp^*||| = d \right\},
\]

where \( |||\overrightarrow{cd}||| > d > 0 \). In practical implementations, \( d \) should be set considering the end-effector size (if too small, the end-effector may collide with the contact), and the camera field of view (large \( d \) may jeopardize contact visibility).

By combining (7) - (9), we obtain a feasible set for \( p^* \):

\[
\left\{ p^* \in \mathbb{R}^2 \mid P' \cap \{|||fp^*||| > |||fe|||\} \cap \{|||cp^*||| = d\} \right\},
\]

which is illustrated in Fig. 9 (purple arc).

The local coordinate frame \( Mxy \) should have its positive \( x \) direction towards \( f \) (the center of rotation). Thus, the target orientation \( \theta^* \) can be calculated as \( \theta^* = \arctan(y_{\Delta}/x_{\Delta}) \), with \( \Delta = f - p^* \).

Extending the method to multi-contact cases is straightforward. For each contact, the fixed point \( f \) is at the previous contact (or at the origin of \( Fxy \) for the first contact). For the last contact, the next contact \( r \) is at the target position. We calculate the planned pose for each contact in the given order. Figure 10 shows a planning example.

Once the planned pose is reached, we go to the pre-contact phase.
Direction of pull is \( c \) in Fig. 11. As discussed in Sec. III, this post-contact rotation is the same as the sliding one, which we analyzed in Sec. III. Since the ACMI stays unchanged during the pull, the cable maintains contact.

The direction of the pull is the same as the sliding one, which we analyzed in Sec. III. Since the ACMI stays unchanged during the pull, the cable maintains contact.

VI. CONTACT DETECTOR

We detect the contact by extracting three features on the in-hand camera image, respectively: the locations of two ends of the cable segment and the contact. The detector is active only when a contact is in the image. To ease extraction, we use a white manipulation plane, a black cable and blue contacts. OpenCV [21] is used for image processing. Below is the procedure to extract these features:

- The blue contact is found via HSV (Hue, Saturation, Value) thresholding.
- The image is binarized using uniform thresholding. Then, the Canny edge detector outputs the contour(s) of the cable in the image.
- Since the relative translation between the cable end held by \( \mathcal{M} \) and the camera is fixed, that cable end is selected as the bottom point on the contour in a small Region Of Interest (ROI). (Fig. 13b orange ROI). The other end of the cable is selected as the upmost point on the contour within the green ROI at the top of the image.
The feature extraction results are shown in Fig. 13b with the end held by \( M \) orange, the other end green, and the contact red.

![Image](a) Original image, (b) Image after processing with locations of three features and ROIs.

Fig. 13. Extraction of the cable ends and the contact: (a). Original image, (b). Image after processing with locations of three features and ROIs

Given the locations of the three features: orange \( e_o = [u_o \ v_o]^T \), green \( e_g = [u_g \ v_g]^T \), and red \( e_r = [u_r \ v_r]^T \) on the image, we detect a contact when the angle between \( e_g e_o \) (Pink dashed arrow in Fig. 13b) and \( e_r e_o \) (Blue dashed arrow in Fig. 13b) is smaller than a threshold (set to 0.1 rad in the robotic experiments).

### VII. ROBOT EXPERIMENTS

#### A. Hardware setup

We use our BAZAR robot [22] which is equipped with two lightweight KUKA LWR IV. Planning is carried out in the task space, then projected in the joint space via inverse kinematics. To avoid kinematic singularities, we use adaptive damped least squares [23]. For a starting pose \( p_s \) and final desired pose \( p_f \) we specified the starting/final velocity and acceleration to be 0, and the maximum (operational space) velocity (0.2 m/s) and acceleration (0.1 m/s²). The trajectory generation is based on second order polynomials. The generation is done by reflexxes motion generation library [24].

A table serves as the manipulation plane. We use cylinder screws as contacts and a board with holes for easy insertion of contacts. A white wall paper covers the board, with only the contacts standing out. The size of the manipulation plane is 0.5 m × 0.9 m.

Figure 14a shows the end-effector \( M \). A cable can be firmly attached at the bottom of it. An Intel Realsense D435 camera is mounted, with height from the bottom adjustable (3–27cm). We only use the camera RGB images. The image resolution is 1920 × 1080. \( F \) is a 3D printed structure with 4 springs. When pressed on the table, it holds the cable; when lifted, it lets the cable slide (Fig. 14b).

Figure 15 shows the coordinate frames. An ArUco marker [25] is placed just below \( F \) to serve as the origin of the manipulation plane. The manipulation plane is parallel to \( XY \) plane in the robot frame.

The transformation from any position \( [X \ Y \ Z]^T \in \mathbb{R}^{XYZ} \) to \( [x \ y]^T \in \mathbb{F}xy \) is \( [x \ y]^T = [X \ Y]^T - [X_F \ Y_F]^T \), where \( [X_F \ Y_F]^T \) is the \( XY \) position of \( F \) in the robot frame.

#### B. Contact localization

The location of contacts in the robot frame is obtained by commanding an initial upward motion of \( M \) to capture an image of the manipulation plane with the ArUco marker. Using this image, with simple HSV thresholding, we find the blue contact locations on the image plane. The projection equation from 3D to 2D is then:

\[
[u \ v \ 1]^T = DCT_{\mathbb{R}}[X \ Y \ Z]^T, \tag{14}
\]

where \( D \in \mathbb{R}^{3×3} \), \( C \in \mathbb{R}^{3×4} \) are respectively distortion and camera matrices, and \( T_{\mathbb{R}} \in \mathbb{R}^{4×4} \) is the transformation from the robot to the camera frame. Both the depth \( Z \) and \( T_{\mathbb{R}} \) can be obtained via ArUco. Given image coordinates \( u \) and \( v \), the projection equation (14) consists of two functions with two unknowns. Thus, we solve the robot frame coordinate \( X \) and \( Y \) from \( u \) and \( v \). The contacts are conventionally ordered with increasing \( X \) axis coordinate.

#### C. Results

To validate our framework, we did 8 experiments with different contact configurations. Figure 16 shows the manipulation time for each experiment scenario³. The majority of time is dedicated to the rotation, during which the contact detector is active. We use a rotation step of 0.02 rad. The rotation step is chosen based on our image processing rate (on average 60 milliseconds per image) for an accurate contact detection. A late detection will put the cable in high tension. With faster image processing, we could reduce the execution time in the rotation phase by taking larger rotation steps. This could be achieved – for instance – by using smaller size images.

Figure 20 presents graphically all the multi-contact scenarios with nominal cable configurations. In the figure, the contact

³We developed a website indicating all the control and vision parameters used in our experiments: https://jihong-zhu.github.io/robotics/2019/08/17/Experiment-contact-based-manipulation.html.
and initial/target $XY$ ($Z$ is constant) locations are given by vectors (in meters) expressed in the robot frame $\mathcal{R}$XYZ. The initial pose of $\mathcal{M}$ is $[-0.05 \ 0.65 \ \pi]^T$. To reach the target, we set the target orientation for $\mathcal{M}$ as $\pi$.

![Fig. 16. Total manipulation time for each scenario. Single contact cases: 1,2. Two contacts cases: 3-5. Three contacts cases: 6-8.](image)

Figure 16 shows the final configuration for six of the eight scenarios. The robot achieves all these configurations by contact regulation. Figure 21 shows a step by step manipulation process for scenario 8.

![Fig. 17. Final cable configurations in six of the eight scenarios.](image)

For the example on Fig. 18b, from the motion and contact locations we are able to calculate $\alpha_1 = 0.76 \text{rad}$ and $\beta_1 = -0.0862 \text{rad}$ ($\beta$ is negative as the direction is different from the rotation direction before the pull). The ACMI for the contact is $2\pi - \pi - 0.76 + 0.086 = 2.46 \text{rad}$. ACMIs for the rest of contacts can be calculated in the same manner.

One simple measure to analyze overall contact mobility is by summing up the ACMI of each contact for a given scenario. The total ACMI for a $n$ contacts setup after robotic manipulation can be calculated by (16):

$$ T = \sum_{i=1}^{n} \text{ACMI}_i. $$  

For a given topology of contact locations (order known), the start and target end-effector positions, one could calculate the nominal total ACMI by the cable configuration. Consider the example in Fig. 18, based on the nominal cable configuration (obtained by connecting the start, contacts in order and the target sequentially), the nominal ACMI for the first contact is $\psi_1$ which is the angle between the $k_1$ and $k_2$ (see Fig. 18). Similarly, using (16) we can calculate total nominal ACMI for a given topology. Figure 19 presents a bar graph of comparison between the nominal and actual ACMI in each scenario. The difference between the nominal ACMI and ACMI calculated from the robot motion is very small. This confirms that with our framework the robot is able to construct contact and to use it for shaping the cable to reach the desired configuration.

In these experiments, we were constrained by the operational space of the robot, and by the simple mechanical structure designed to hold the cable. To extend the framework for more contacts one needs to consider: 1. re-grasping of the cable, 2. using a mobile base to enlarge the robot operational space.

![Fig. 18. (a): Planned motion for scenario 8; (b): Example calculation of the ACMI of contact 1 after the robot motion.](image)

We can analyze the effect of robot motion on the ACMI for individual contact and then for the overall experiment. For an experiment with $n$ contacts, the initial overall ACMI is $2\pi n$. We expect the ACMI to decrease as the cable is regulated by each contact. The initial overall ACMI for scenario 8 is $3 \times 2\pi = 6\pi$. Given the motion in Fig. 18a, we can calculate the ACMI for the $i^{th}$ contact as shown on Fig. 18b:

$$ \text{ACMI}_i = 2\pi - \pi - \alpha_i - \beta_i. $$  

The $-\pi$ in (15) comes from the first contact detected by the vision-based detector. A point contact is then constructed.

![Fig. 19. The nominal ACMI and the ACMI after the manipulation.](image)

The $\alpha_i > 0$ is the rotation angle subsequent to the contact detection. The $\beta_i \in [-\pi, \pi]$ is the rotation angle after pull until the next contact is detected; $\beta_i$ is positive if the rotation after the pull has the same direction as before the pull, and negative otherwise. For the last contact $\beta_n = 0 \text{rad}$. The $\alpha_i$ and $\beta_i$ are determined for the first contact detected by the vision-based detector.
We believe contacts play a vital role in deformable objects manipulation. Currently, since we use a fixed base, the number of contacts is limited, as is the robot operational space. With a mobile base, one could enhance the robot operational range. In addition, since the rationale behind a human using a specific contact for shaping is probably closely related to cognitive science, some inspiration can be drawn from [26] for studying how robots should use different contacts. In a nutshell, contact for deformable objects manipulation is a rich area with a lot of new research opportunities. We hope this work can be a starting point for future research.
