Abstract

We present a perturbation theory of the market impact based on an extension of the framework proposed by [Loeper, 2018] – originally based on [Liu and Yong, 2005] – in which we consider only local linear market impact. We study the execution process of hedging derivatives and show how these hedging metaorders can explain some stylized facts observed in the empirical market impact literature. As we are interested in the execution process of hedging we will establish that the arbitrage opportunities that exist in the discrete time setting vanish when the trading frequency goes to infinity letting us to derive a pricing equation. Furthermore our approach retrieves several results already established in the option pricing literature such that the spot dynamics modified by the market impact. We also study the relaxation of our hedging metaorders based on the fair pricing hypothesis and establish a relation between the immediate impact and the permanent impact which is in agreement with recent empirical studies on the subject.

Keywords: Market microstructure, option pricing, market impact, metaorders execution, option hedging, metaorders relaxation, fair pricing.

1 Introduction

This paper presents a perturbation theory of the market impact. We will consider the framework of covered options. To illustrate our perturbative approach, let us consider an option’s hedger who has to deal with a feedback mechanism between the underlying price dynamics and the option’s delta-hedging, better know as market impact. Let us consider a market impact rule obeying:

\[ S_\ast \to S_\ast + f(S_\ast, N_\ast), \]

which means that the impact on the stock price of an order to buy \( N_\ast \) stocks at a price \( S_\ast \) is \( f(S_\ast, N_\ast) \). From the point of view of the option’s hedger, if the spot moves from \( S \) to \( S + dS_0 \), he will buy \( \Gamma dS_0 \) stocks, but doing this, due to the market impact rule (1) the spot price will move to \( S + dS_0 + dS_1 \) where \( dS_1 \) will be given by \( dS_1 = f(S + dS_0, \Gamma dS_0) \). But again to adjust the hedging, he has to buy \( \Gamma dS_1 \) stocks which in turns impacts the spot price by \( dS_2 = f(S + dS_0 + dS_1, \Gamma dS_1) \) and so on and so forth. This perturbative approach taking to the limit \( n \to +\infty \), where \( n \) represent the number of transactions of the re-hedging procedure, will move the spot:

\[ S \to S + \sum_{n=0}^{+\infty} dS_n. \]
From a realistic trading perspective, a re-hedging procedure leading to the divergence of the market impact series $\sum_{n \geq 0} dS_n$ cannot be acceptable, therefore we will need to study some convergence properties of the market impact series derived from the market impact rule (1) described above. The convergence of the market impact series $\sum_{n \geq 0} dS_n$ has several main physical consequences that seem necessary. First it implies that the market impact has only a limited effect on the stock price, secondly the incremental impact $dS_n$ vanish where $n \to +\infty$. Those properties have already been observed empirically in the U.S. equity market [Bucci et al., 2019a] and in the European equity market [Said et al., 2018] highlighting the fact that at the end of certain large metaorders the incremental impacts vanish letting the total market impact reaching a plateau. In our framework, as we will only consider a perturbative approach, the initial exogenous spot move $dS$ will be supposed small enough. In that case, the following re-hedging trades will be considered also small and we will show how this implies to consider at this scale local linear market impact rule. Indeed it is well established that the response to individual small orders are linear and it is only the aggregation of those small orders executed consecutively, better known as metaorders, which lead to concave market impact in agreement to a square-root law in the equity markets [Moro et al., 2009] [Bacry et al., 2015] [Toth et al., 2011] but also in the options market [Toth et al., 2016] [Said et al., 2019]. The multi-timescale property of the market impact has also been recently addressed in [Benzaquen and Bouchaud, 2018].

The rest of the paper is organized as follows. Section 2 presents our order book assumptions and the way it leads in our perturbative approach to local linear market impact. Section 3 gives the main results presented in the paper. Section 4 introduces the main definitions of the perturbation theory and gives the convergence results about the market impact series. Section 5 presents some results on the execution of metaorders in our setting. Section 6 presents the derivation of the pricing equation based on the results of the previous sections. Section 7 studies the shape and the relaxation of our hedging metaorders. Section 8 recalls and discusses our main results and makes some connections with related works.

2 Order book modeling and local linear market impact

Let us consider an order book parametrized by a mid price $\mathcal{S}$ and a supply intensity $\eta(t, s)$ such as the units of stocks available at the instant $t$ on the limit order book between $\mathcal{S}$ and $\mathcal{S} + d\mathcal{S}$ is equal to $\eta(t, \mathcal{S})d\mathcal{S}$. Of course the order book approach presented here is a trivial simplification of what is really observed on the markets. More accurate descriptions are given for instance in [Biais et al., 1995] and [Toth et al., 2012]. For a more detailed order book modeling, see for example [Cont et al., 2010] and [Abergel and Jedidi, 2013].

In our order book perspective, the execution of an amount $A$ (expressed in currency) will consume the order book up to $\mathcal{S} + \varepsilon(A)$, where $\varepsilon(A)$ is defined such as

$$A = \int_{\mathcal{S}}^{\mathcal{S} + \varepsilon(A)} s\eta(t, s) \, ds,$$

whereas the number $N(A)$ of stocks purchased to execute the amount $A$ must satisfy

$$N(A) = \int_{\mathcal{S}}^{\mathcal{S} + \varepsilon(A)} \eta(t, s) \, ds.$$

In agreement with the intuition, we expect that a small order has only a small impact on the spot price, hence we will assume that $\varepsilon(0) = 0$ and $\varepsilon$ is continuous in 0. As we will consider only small orders, we will be interested in the behaviour of $\varepsilon$ around 0 at the leading order in $A$. The function $\varepsilon$ as defined above allows us to capture the liquid character or not of an underlying.
Indeed to illustrate this, let us consider two particular cases: The one of a super liquid stock with \( A \gg \varepsilon(A) \) and the second one of a very poor liquid equity satisfying \( A \sim \varepsilon(A) \) which reads that \( A \) and \( \varepsilon(A) \) are the same order of magnitude. Those considerations motivate to define the market depth \( L(t, S) \) at \( S \) by

\[
L(t, S) := \lim_{A \to 0} \frac{A}{\varepsilon(A)}.
\]

We have

\[
\frac{A}{\varepsilon(A)} = \frac{1}{\varepsilon(A)} \int_S^{S+\varepsilon(A)} s\eta(t, s) \, ds \xrightarrow{A \to 0} \eta(t, S),
\]

and

\[
\frac{N(A)}{\varepsilon(A)} = \frac{1}{\varepsilon(A)} \int_S^{S+\varepsilon(A)} \eta(t, s) \, ds \xrightarrow{A \to 0} \eta(t, S).
\]

This gives that

\[
\varepsilon(A) = \frac{\varepsilon(A)}{N(A)S} \times N(A)S \sim_{A \to 0} \frac{1}{\eta(t, S)S} \times N(A)S.
\]

By setting

\[
\lambda(t, S) := \frac{1}{L(t, S)} = \frac{1}{\eta(t, S)S},
\]

we have \( \varepsilon(A) \sim_{A \to 0} \lambda(t, S)N(A)S \) corresponding to linear market impact for \( A \) small enough. Therefore we have established the following local linear market impact rule:

\[
S_* \to S_* + \lambda(t, S_*)S_* N_*,
\]

which is valid when the order size \( N_* \) is small enough. When \( \lambda(t, S) \equiv \lambda \in \mathbb{R}_+ \) we retrieve the market impact rule given in [Abergel and Loeper, 2017] where the impact is given by

\[
S_* (e^{\lambda N_*} - 1) \sim_{N_* \to 0} \lambda S_* N_*.
\]

The case \( \lambda(t, S) \equiv \lambda S \) with \( \lambda \in \mathbb{R}_+ \) corresponds to the market impact rule presented in [Loeper, 2018]:

\[
S_* \to S_* + \lambda S_*^2 N_*.
\]

In what follows we will consider indifferently \(5\) or \(6\) by introducing

\[
S_* \to S_* + \lambda S_*^{1+\zeta} N_*,
\]

where \( \zeta \in \{0, 1\} \). One must notice that depending of the choice of \( \zeta \) the dimension of the parameter \( \lambda \) can vary.

3 Context and main results

Let us suppose the market impact rule \(7\) hold, and consider an agent who is short of an european style option for instance. Taking in to account market impact, if the spot moves from \( S \) to \( S + dS \) the agent is going to try to react to the exogenous market move \( dS \) by adjusting his hedge by purchasing \( N \) stocks. This will result in a final state

\[
S + dS + (S + dS)^{1+\zeta} \lambda N,
\]

and as the trader wants to be hedged at the end of the day, \( N \) must satisfy the following equation

\[
\Gamma(t, S + dS)(dS + (S + dS)^{1+\zeta} \lambda N) = N
\]
leading to

\[ N = \frac{\Gamma(t, S + dS) dS}{1 - (S + dS)^{1+\xi} \lambda \Gamma(t, S + dS)}. \]

Let us assume that \( x \mapsto \frac{\Gamma(t, x)}{1 - \lambda x^{1+\xi} \Gamma(t, x)} \) has a Taylor series expansion in the neighbourhood of any \( S \), hence \( N \) can be read

\[ N = \frac{\Gamma(t, S + dS)}{1 - (S + dS)^{1+\xi} \lambda \Gamma(t, S + dS)} + \frac{\Gamma(t, S) dS}{1 - \lambda S^{1+\xi} \Gamma(t, S)} + c_2(t, S)(dS)^2 + c_3(t, S)(dS)^3 + \ldots \] (8)

giving \( N \approx \frac{\Gamma(t, S) dS}{1 - \lambda S^{1+\xi} \Gamma(t, S)} \) at the leading order in \( dS \). So everything happens as if the market impact has affected the dynamics of the spot in

\[ d\tilde{S} = \frac{dS}{1 - \lambda S^{1+\xi} \Gamma(t, S)} \] (9)
at the first order. This approach was developed in [Loeper, 2018] by considering (9) as an ansatz to derive his pricing equation. Modified spot dynamics generated by market impact has been also discussed in [Bouchard et al., 2016]. As \( dS \) and \( d\tilde{S} \) need to have the same sign, we have necessarily

\[ \sup_{(t, S) \in [0, T] \times \mathbb{R}_+} \lambda S^{1+\xi} \Gamma(t, S) < 1 \] (10)

with \( T > 0 \) fixed. The condition (10) and its variants are admitted in several papers on the topic (see [Liu and Yong, 2005] [Abergel and Loeper, 2017] and [Loeper, 2018] for instance). However this important question has always been left aside and often assumed in order to derive a pricing equation with exact replication of european style options. From a mathematical point of view it is always possible to replace the pricing equation \( P = 0 \) by \( \max(P, \lambda S^{1+\xi} \Gamma(t, S) - 1) = 0 \) as suggested in [Loeper, 2018].

At this stage, there is also another point that needs to be discussed. Most papers on option pricing and hedging with market impact deal with linear impact as done in [Bouchard et al., 2016] [Bouchard et al., 2017] and [Loeper, 2018] for example. However, although this approach is acceptable for small trades is clearly not realistic for large orders in terms of market microstructure. Besides when it comes trades with sufficiently large size, it is not realistic to state that a large order can be executed in a single trade. Hence it becomes necessary to study the execution process of hedging.

The main objective of this paper is to show however that the option pricing approaches developed mainly in [Liu and Yong, 2005] [Abergel and Loeper, 2017] and [Loeper, 2018] are compatible with the market impact foundations mainly based on the study of the metaorders. The first step done in this direction has been presented in [Abergel and Loeper, 2017]. In their paper the authors integrate in their option pricing model a relaxation factor to illustrate the results obtained of the permanent impact in the metaorders. Our paper is a contribution of this strand of research as our main goal is to provide some realistic connections between option pricing theory and market impact empirical findings. To this end our approach is mainly inspired by the original definition of a metaorder which is nothing less than a large order split into several small orders to be executed incrementally. Besides it has been shown in two companion papers ([Said et al., 2018] and [Said et al., 2019]) that the metaorders can obey to an algorithmic definition. This implies that they are not necessarily driven by execution strategies but they are
more often simply opportunistic or hedging trades. So as the vast majority of the meatorders executed on the markets appear to be hedging trades they must explain the market impact curves observed in several studies. We will introduce a hedging procedure – as presented in Section 1 based on a local linear market impact rule (4) – composed of successive small orders each of them impacting the price by \( dS_n \). Under a Gamma constant approximation we will show that the market impact series \( \sum_{n \geq 0} dS_n \) is convergent if and only if the condition (10) holds. This result gives a physical meaning to the condition (10) as it linked the convergence of the market impact series with the possibility to derive a pricing equation. We will also show that the sum of the market series \( \sum_{n \geq 0} dS_n \) can be expressed as in (8). Hence what was considered as an ansatz (9) in [Loeper, 2018] is now simply a consequence of the convergence of the market impact series.

4 Market Impact and Hedging: A perturbation theory of the market impact

In this section we give the main results based on our perturbation theory of the market impact which will be useful to derive the pricing equation. For ease of notations, we will not consider any interest rates or dividends in the rest of the paper.

Let us consider that we have sold an european style option whose value is \( u(t,s) \) with a fixed maturity \( T \). Greeks are given as usual by

\[
\Delta(t,s) = \frac{\partial}{\partial s} u(t,s), \\
\Gamma(t,s) = \frac{\partial^2}{\partial s^2} u(t,s) = \frac{\partial}{\partial s} \Delta(t,s), \\
\Theta(t,s) = \frac{\partial}{\partial t} u(t,s).
\]

In order to derive a pricing equation, we will be interested in small enough spot moves. We have already established in Section 2 that this leads to consider linear market impact rule in the framework of our perturbation theory. Therefore in what follows we will take a market impact which reads:

\[
S \rightarrow S + \lambda S^1 + \zeta N
\]

i.e. the impact of an order to buy \( N \) stocks at a price \( S \) is \( \lambda S^1 + \zeta N \) when the size \( N \) of the order is sufficiently small (linear market impact). We set the parameter \( \phi \) defined by

\[
\phi \equiv \phi(t,S) := \lambda S^1 + \zeta \frac{\partial}{\partial s} u(t,S) = \lambda S^1 + \zeta \Gamma(t,S).
\]

We assume an initial spot moves from \( S \) to \( S + dS \), \( dS \) supposed to be small and \( S > 0 \). By following an iterative hedging strategy one has to adjust the hedge by \( \Gamma dS \) stocks after the initial spot move \( S \rightarrow S + dS \), which then again impacts the spot price by \( dS_1 = \lambda(S + dS_0)^1 + \zeta \Gamma dS_0 \) according to the linear market impact rule presented above with \( dS_0 = dS \). This spot move is then followed by a second hedge adjustment of \( \Gamma dS_1 \), which in turn impacts the spot price by \( dS_2 = \lambda(S + dS_0 + dS_1)^1 + \zeta \Gamma dS_1 \) and so on and so forth. Hence one has

\[
\begin{align*}
\left\{ \\
\forall n \in \mathbb{N}, dS_{n+1} &= \lambda \left( S + \sum_{k=0}^{n} dS_k \right)^1 + \zeta \Gamma dS_n = \phi \left( 1 + \frac{1}{S} \sum_{k=0}^{n} dS_k \right)^{1+\zeta} dS_n
\end{align*}
\]

with the assumptions that \( \Gamma \equiv \Gamma(t,S) \) remain constant during the hedging procedure described just above. The Gamma approximation appears also in [Almgren and Li, 2016] and considerably
simplifies the problem by eliminating the dependence of the variable state \( S_t \) in the expression of \( \Gamma \). Hence the approximation that \( \Gamma \) is constant during the hedging procedure allows us to exhibit the essential features of the local hedging without losing ourselves in complexities. Furthermore from the numerical point of view, this hypothesis is clearly justified in the context of the perturbative approach proposed here. In what follows we will show that for \( dS \) small enough, the total market impact \( \sum_{n=0}^{+\infty} dS_n \) will be also small enough. In the context of our approach as the market impact is only considered as a perturbation we have that

\[
\Gamma \left( t, S + \sum_{n=0}^{+\infty} dS_n \right) \approx \Gamma(t, S) + \partial_s \Gamma(t, S) \sum_{n=0}^{+\infty} dS_n \approx \Gamma(t, S).
\]

Besides considering the fact that the price is bounded below by 0 it is more relevant to write

\[
\begin{aligned}
\left\{ \begin{array}{l}
dS_0 = dS \lor (-S) \\
\forall n \in \mathbb{N}, dS_{n+1} = \phi \left( 1 + \frac{1}{S} \sum_{k=0}^{n} dS_k \right)^{1+\zeta} dS_n \lor \left( -\sum_{k=0}^{n} dS_k - S \right)
\end{array} \right. \tag{13}
\end{aligned}
\]

with for all \( a, b \in \mathbb{R}, \max(a,b) = a \lor b \). For all \( n \in \mathbb{N}, dS_n \) being a function of \( dS \), we will denote by now \( x \) for the exogenous spot move \( dS \) and \( u_n \) for the \( n \)–th impact \( dS_n \). Hence we introduce for ease of notations the sequence of real valued functions \((u_n)_{n \in \mathbb{N}}\) defined by for all \( x \in \mathbb{R},
\[
\begin{aligned}
\left\{ \begin{array}{l}
u_0(x) = x \lor (-S) \\
\forall n \in \mathbb{N}, u_{n+1}(x) = \phi \left( 1 + \frac{s_n(x)}{S} \right)^{1+\zeta} u_n(x) \lor (-s_n(x) - S)
\end{array} \right. \tag{14}
\end{aligned}
\]

where \( s_n := \sum_{k=0}^{n} u_k \) denote the partial sums of the series \( \sum_{n \in \mathbb{N}} u_n \). As \( s_n \) represent the cumulative market impact after \( n \) successive re-hedging trades, from a realistic trading perspective this quantity cannot exploded, hence we will add the following constraint:

**Assumption 1.** For all \( x \in \mathbb{R} \), the sequence \((s_n(x))_{n \in \mathbb{N}}\) is bounded.

In the context of our perturbation theory of the market impact, it will be necessary to study the convergence properties of the market impact series derived from the local linear market impact rule (4) given previously. To this end, we introduce what we will call a **market impact scenario**:

**Definition 1.** A sequence \((u_n)_{n \in \mathbb{N}}\) defined by (14) is said to be a **market impact scenario** starting from \( x \in \mathbb{R} \).

A market impact scenario can be seen as an extension of the definition given for a metaorder (see Definition 8 given in Section 7). We have this first elementary result:

**Proposition 1.** Let \((u_n)_{n \in \mathbb{N}}\) an \( \phi \)–market impact scenario. Then \((s_n)_{n \in \mathbb{N}}\) is uniformly bounded below by \(-S\).

**Proof.** Let \((u_n)_{n \in \mathbb{N}}\) an \( \phi \)–market impact scenario starting from \( x \in \mathbb{R} \). We proceed by induction.

- \( s_0(x) = u_0(x) = x \lor (-S) \geq -S \).

- Let \( n \in \mathbb{N} \) and suppose that \( u_n(x) \geq -S \). We have \( u_{n+1}(x) \geq -s_n(x) - S \) which gives \( s_{n+1}(x) \geq -S \).
Hence we have shown that for all \( x \in \mathbb{R}, n \in \mathbb{N}, s_n(x) \geq -S \).

Among the market impact scenarios, we must distinguish between those that are acceptable from those that are not. The following definition is here to give an admissibility criterion:

**Definition 2.** A market impact scenario \((u_n)_{n \in \mathbb{N}}\) is said to be admissible from a trading perspective if there exists \( R > 0 \) such that for any \( x \in (-R, R), \sum_{n \in \mathbb{N}} u_n(x) \) converges.

The following result will give an equivalent criterion on the parameter \( \phi \) for a market impact scenario to be admissible. We have that:

**Theorem 1.** The \( \phi \)-market impact scenario \((u_n)_{n \in \mathbb{N}}\) is admissible from a trading perspective if, and only if, \( \phi \in (-\infty, 1) \).

**Proof.** see Appendix A.1.

The previous result establish a straightforward connection between the range values of the parameter \( \phi \) and the convergence of the market impact series. Actually the proofs of Theorem 1 given state much more than that. We have in fact the following result:

**Theorem 2.** Let \((u_n)_{n \in \mathbb{N}}\) an \( \phi \)-market impact scenario. The following statements are equivalent:

(i) The market impact scenario \((u_n)_{n \in \mathbb{N}}\) is admissible from a trading perspective.

(ii) \( \phi \in (-\infty, 1) \).

(iii) There exists \( R > 0 \) such that for any \( x \in (-R, R), \sum_{n \geq 0} u_n(x) \) converges.

(iv) There exists \( R > 0 \) such that for any \( x \in (-R, R), \sum_{n \geq 0} u_n(x) \) converges absolutely.

**Proof.** This result is an immediate corollary of the proofs given for the Propositions A.1.1, A.1.2, A.1.3 and A.1.4.

From now on, we consider only market impact scenarios that are admissible from a trading perspective which is, according to Theorem 1, equivalent to considering values of \( \phi \) in \((-\infty, 1)\). We give now an expression of the market impact series for admissible market impact scenarios, in particular one can notice that we retrieve the first order term of the taylor expansion introduced above.

**Proposition 2.** Let \((u_n)_{n \in \mathbb{N}}\) an \( \phi \)-market impact scenario admissible from a trading perspective starting from \( x \in \mathbb{R} \) and

\[
N(x) := \inf \left\{ n \in \mathbb{N} \left | s_n(x) = -S \right. \right\} \quad (15)
\]

with the convention \( \inf \emptyset = +\infty \). Then there exists \( R > 0 \) such that for all \( x \in (-R, R), N(x) \in \mathbb{N}^* \cup \{+\infty\} \) and

\[
\sum_{n=0}^{N(x)} u_n(x) = \frac{x}{1 - \phi} + \frac{1}{S} \frac{(1 + \zeta)\phi}{1 - \phi} \sum_{n=0}^{N(x)} s_n(x)u_n(x) + \frac{1}{S^2} \frac{\zeta\phi}{1 - \phi} \sum_{n=0}^{N(x)} s_n^2(x)u_n(x). \quad (16)
\]

**Proof.** see Appendix A.2.
Among the admissible market impact scenarios, three can be distinguished. Firstly the trivial scenario where nothing strictly happens which consists for the price in reaching 0 after the first exogenous spot move. Namely this corresponds to $u_0(x) = -S$. In this case there is nothing much to say. The second is to reach 0 after a finite number of re-hedging trades. In that case it is the market impact that brings the price stock to 0. And finally the third one and more realistic one implying an infinite number of re-hedging trades and putting the stock price at a non-zero different level. The definition given just below presents the three possibilities:

**Definition 3.** Let $(u_n)_{n \in \mathbb{N}}$ an $\phi$–market impact scenario admissible from a trading perspective starting from $x \in \mathbb{R}$ and $N(x)$ as defined in (15). The market impact scenario $(u_n)_{n \in \mathbb{N}}$ is said to be:

- **null** when $N(x) = 0$.
- **chaotic** when $N(x) \in \mathbb{N}^*$. 
- **regular** when $N(x) = +\infty$.

In the rest of the section, we will only consider chaotic or regular market impact scenarios. Especially we will show (see Proposition 3) that for $\phi \in (-1, 1)$, when the initial spot move is small enough, which is clearly the case of interest in our perturbative approach, it is always possible to consider only regular market impact scenarios. Particularly, it will be the case of our hedging metaorders discussed later (see Section 7).

**Proposition 3.** Let $(u_n)_{n \in \mathbb{N}}$ an $\phi$–market impact scenario admissible from a trading perspective. For any $\phi \in (-1, 1)$, there exists $R > 0$, such that for all $x \in (-R, R)$, the $\phi$–market impact scenario $(u_n)_{n \in \mathbb{N}}$ is regular.

**Proof.** see Appendix A.3. 

The following proposition shows that in the case of regular market impact scenarios with $\phi \in (-1, 1)$ the market impact series is nothing less than a power series. In particular we obtain a closed form for the second order term of the market impact series. We recall that the first linear order term has been already given in any case (chaotic or regular) in Proposition 2.

**Proposition 4.** Let $\phi \in (-1, 1)$ and $(u_n)_{n \in \mathbb{N}}$ an $\phi$–market impact scenario admissible from a trading perspective. There exists $R > 0$, such that for all $x \in (-R, R)$, the $\phi$–market impact scenario $(u_n)_{n \in \mathbb{N}}$ is regular. Hence the series function $\sum_{n \geq 0} u_n$ can be expressed as a power series on $(-R, R)$, is of class $C^\infty$ on $(-R, R)$ and the first two terms of the decomposition of $\sum_{n \geq 0} u_n$ as a power series are given by

$$\sum_{n=0}^{+\infty} u_n(x) = \frac{1}{1 - \phi} x + \frac{1}{3} \frac{(1 + \zeta)\phi}{(1 - \phi)(1 + \phi)} x^2 + o(x^2) \text{ as } x \to 0.$$ 

**Proof.** see Appendix A.4. 

## 5 Market Impact and Metaorders Execution

### 5.1 $\lambda(t, S) \equiv \lambda$

Let us consider the market impact rule (11) when $\zeta = 0$

$$S_x = S_x + \lambda S_x N_x. \quad (17)$$
Assume an agent wants to execute incrementally an order of size \( N \) with \( K \in \mathbb{N}^* \) child orders of size \( n_1, n_2, \ldots, n_K \) satisfying
\[
\sum_{k=1}^{K} n_k = N.
\]
Without loss of generality we will suppose that \( N \in \mathbb{R}_+^* \) and \( n_1, \ldots, n_K \in \mathbb{R}_+^* \) – i.e. a buy order, the same holds for a sell order – such that
\[
\lim_{K \to +\infty} \sup_{1 \leq k \leq K} |n_k| = 0.
\] (18)
The condition (18) is needed to ensure that (17) can be applied to \( n_1, \ldots, n_K \) for \( K \) large enough. Applying this when \( K = 2 \) leads to
\[
S \xrightarrow{n_1} S + \lambda S n_1 \xrightarrow{n_2} S + \lambda S n_1 + \lambda(S + \lambda S n_1)n_2,
\]
which can be written
\[
S \xrightarrow{n_1} S(1 + \lambda n_1) \xrightarrow{n_2} S(1 + \lambda(n_1 + n_2) + \lambda^2 n_1 n_2).
\]
Let us denote \( n_1, \ldots, n_K \rightarrow \) the contraction of \( n_1 \ldots n_K \). By a straightforward induction we have for all \( K \in \mathbb{N}^* \),
\[
S \xrightarrow{n_1 \ldots n_K} S \left( 1 + \sum_{k=1}^{K} \lambda^k \sum_{1 \leq i_1 < i_2 < \cdots < i_k \leq K} n_{i_1} n_{i_2} \cdots n_{i_k} \right).
\]

**Definition 4.** Let \( N \in \mathbb{R}_+^* \) and \( K \in \mathbb{N}^* \). A finite sequence \( (n_1, \ldots, n_K) \in (\mathbb{R}_+^*)^K \) such that \( \sum_{k=1}^{K} n_k = N \) is said to be an \((N, K)\)-execution strategy. An \((N, K)\)-execution strategy is considered admissible if it satisfies (18).

**Definition 5.** Let \( (n_1, \ldots, n_K) \) an \((N, K)\)-execution strategy. Let us denote by
\[
S_{N,k}(n_1, \ldots, n_K) := S \left( 1 + \sum_{i=1}^{k} \lambda^i \sum_{1 \leq j_1 < j_2 < \cdots < j_i \leq K} n_{j_1} n_{j_2} \cdots n_{j_i} \right)
\]
the \( k \)-th price of this \((N, K)\)-execution strategy for \( k \in [0, K] \). Then let us set its market impact by
\[
I_{N,K}(n_1, \ldots, n_K) := S_{N,K}(n_1, \ldots, n_K) - S
\]
and its average execution price by
\[
\overline{S}_{N,K}(n_1, \ldots, n_K) := \frac{1}{N} \sum_{k=1}^{K} n_k S_{N,k-1}(n_1, \ldots, n_K).
\]

**Proposition 5.** Let \( N \in \mathbb{R}_+^* \) and \( K \in \mathbb{N}^* \). The market impact of an \((N, K)\)-execution strategy depends only on the sizes of the \( K \) child orders. The order in which the child orders are executed does not affect the final value of \( I_{N,K}(n_1, \ldots, n_K) \).

**Proof.** Let \( (n_1, \ldots, n_K) \) an \((N, K)\)-execution strategy and \( \sigma \in S_K \) the set of the permutations of \([1, K]\). The result is a straightforward consequence of the fact that for any permutation \( \sigma \in S_K \),
\[
I_{N,K}(n_{\sigma(1)}, \ldots, n_{\sigma(K)}) = I_{N,K}(n_1, \ldots, n_K).
\]
Proposition 5 has shown that for a given \((N,K)\)--execution strategy any permutation of \((n_1,\ldots,n_K)\) is similar in terms of market impact. The point underlined by Proposition 5 is in fact a well known property of market impact which appears in the litterature through the square root formula or other related formulas. The square root formula expresses the final market impact of a metaorder as a function of its size but it doest not tell much about the dynamics itself of the metaorder.

The following result (Theorem 3) shows that among all the \((N,K)\)--execution strategies the one which impacts the most the market is the most predictable one. Indeed given a metaorder size \(N\) and \(K\) child orders the first execution strategy that comes in mind is to split the metaorder in lots of equal size. But doing that could be considerably increase the probability to be detected by the market makers especially when \(K\) becomes large enough. Hence it seems normal that the most expensive strategy in terms of market impact and average execution price corresponds to the most obvious and the less clever.

**Theorem 3.** Let \(N \in \mathbb{R}_+^* \text{ and } K \in \mathbb{N}^*\). The market impact and the average execution price of an \((N,K)\)--execution strategy are bounded and reach their upper bound if, and only if the strategy is equally-sized i.e. \(n_1 = \cdots = n_K = \frac{N}{K}\). Besides the following inequalities hold

\[
S + \lambda SN \leq S_{N,K}(n_1,\ldots,n_K) \leq Se^{\lambda N} \tag{19}
\]

and

\[
S + \frac{1}{2} \lambda S \left(N - \sup_{1 \leq k \leq K} n_k\right) \leq S_{N,K}(n_1,\ldots,n_K) \leq S e^{\lambda N} - \frac{1}{\lambda N} \tag{20}
\]

**Proof.** see Appendix A.5.

The lower bound of (19) corresponds to the linear market impact model presented in [Loeper, 2018] and the upper bound to the one presented in [Abergel and Loeper, 2017]. One can notice that these two bounds do not depend of the execution strategy chosen – as they are independant of the sizes and the number \(K\) of the child orders – but only of the final size \(N\) of the order. This has the advantage of avoiding arbitrage opportunities, as well as not being sensitive to the hedging frequency. One can notice that \(S_{N,K}(n_1,\ldots,n_K) \approx S + \gamma \lambda NS\) when \(N \to 0\) in agreement with (17). Hence the lower bound of (19) can be reached when \(N\) is small enough. More interesting, regarding metaorders with a size \(N\) much larger, we will show that the upper bound of (19) corresponds to the case when the number of child orders \(K\) goes to infinity. This result seems pretty obvious from a market making perspective. Indeed when \(K \to +\infty\) the probability that the market makers detect the metaorder is going to converge towards 1 and the market impact is going to attain its peak value.

**Theorem 4.** Let \((n_1,\ldots,n_K)\) an admissible \((N,K)\)--execution strategy i.e. such that

\[
\lim_{K \to +\infty} \sup_{1 \leq k \leq K} |n_k| = 0.
\]

Then we have that

\[
\lim_{K \to +\infty} S_{N,K}(n_1,\ldots,n_K) = Se^{\lambda N} \tag{21}
\]

and

\[
\lim_{K \to +\infty} \overline{S}_{N,K}(n_1,\ldots,n_K) = S e^{\lambda N} - \frac{1}{\lambda N} \tag{22}
\]

Hence when \(K\) goes to infinity the market impact attains its peak value. Furthermore the market impact and the average execution price do not depend longer of the execution strategy chosen. This implies that arbitrage opportunities vanish when the trading frequency is going to infinity.
Proof. see Appendix A.6.

Remark 1. Theorem 4 is actually true for \( n_1, \ldots, n_K \in \mathbb{R} \) not necessarily positive by weakening (18) and assuming that for some \( \varepsilon > 0 \), \( \sup_{1 \leq k \leq K} |n_k| = O \left( \frac{1}{k} \right)^{1/2 + \varepsilon} \).

Remark 1 states in fact that when \( K \to +\infty \) there does not exist any trading strategy that could affect the average execution price or the final market impact. In other words it is not possible to manipulate the price formation process by executing round trip trades as defined and studied in [Gatheral, 2010] and [Alfonsi and Schied, 2010] for instance. Theorem 4 motivates to extent market impact and average execution price definitions for continuous execution strategies by:

Definition 6. Let \( N \in \mathbb{R} \). A function \( F : [0,1] \to \mathbb{R} \) of bounded variation and continuous such that \( F(0) = 0 \) and \( F(1) = N \) is said to be an \((N, +\infty)\)-execution strategy. Any \((0, +\infty)\)-execution strategy is said to be a round trip trade.

Definition 7. Let \( N \in \mathbb{R} \). The market impact of an \((N, +\infty)\)-execution strategy is given by

\[
I_{N, +\infty} := S e^{\int_0^1 dF(s)} - S = S e^{\lambda N} - S
\]

and the average execution price by

\[
S_{N, +\infty} := \frac{\int_0^1 S e^{\lambda F(s)} dF(s)}{\int_0^1 \lambda dF(s)} = S e^{\lambda N} - \frac{1}{\lambda N}.
\]

One can see in (23)-(24) how the choice of the continuous execution strategy \( F \) does not affect the market impact and the average execution price in agreement with Theorem 4.

5.2 \( \lambda(t, S) \equiv \lambda S \)

Let us consider now the market impact rule (11) when \( \zeta = 1 \)

\[
S_\ast \to S_\ast + \lambda S^2 N_\ast.
\]

Let us show that under the condition (18) all the results of this case can be derived from the previous one by considering the following approximation

\[
(1 + x)^2 \approx 1 + 2x,
\]

when \( x \) is small enough. When \( K = 2 \) we have

\[
S \xrightarrow{n_1} S + \lambda S^2 n_1 \xrightarrow{n_2} S + \lambda S^2 n_1 + \lambda S^2 (1 + \lambda S n_1)^2 n_2 \approx \lambda S^2 (1 + 2\lambda S n_1) n_2
\]

leading approximately to

\[
S \xrightarrow{n_1} S + \lambda S^2 n_1 \xrightarrow{n_2} S \left( 1 + \frac{1}{2} (2\lambda S)(n_1 + n_2) + \frac{1}{2} (2\lambda S)^2 n_1 n_2 \right).
\]

A straightforward induction gives for all \( K \in \mathbb{N}^\ast \),

\[
S \xrightarrow{n_{k_1}, \ldots, n_{K}} S \left( 1 + \frac{1}{2} \sum_{k=1}^K (2\lambda S)^k \sum_{1 \leq i_1 < i_2 < \cdots < i_k \leq K} n_{i_1} n_{i_2} \cdots n_{i_k} \right).
\]

Hence all the results derived in the previous section still hold. Particularly Theorems 3 and 4 can now be written.
Theorem 5. Let \( N \in \mathbb{R}_+^* \) and \( K \in \mathbb{N}^* \). The market impact and the average execution price of an \((N, K)\)-execution strategy are bounded and reach their upper bound if, and only if the strategy is equally-sized i.e. \( n_1 = \cdots = n_K = \frac{N}{K} \). Besides the following inequalities hold
\[
S + \lambda S^2 N \leq S_{N,K}(n_1, \ldots, n_K) \leq \frac{S}{2} \left(1 + e^{2\lambda SN}\right)
\]
and
\[
S + \frac{1}{2} \lambda S^2 \left( N - \sup_{1 \leq k \leq K} n_k \right) \leq S_{N,K}(n_1, \ldots, n_K) \leq \frac{S}{2} \left(1 + \frac{e^{2\lambda SN} - 1}{2\lambda SN}\right).
\]

Theorem 6. Let \((n_1, \ldots, n_K)\) an admissible \((N, K)\)-execution strategy i.e. such that
\[
\lim_{K \to +\infty} \sup_{1 \leq k \leq K} |n_k| = 0.
\]
Then we have that
\[
\lim_{K \to +\infty} S_{N,K}(n_1, \ldots, n_K) = \frac{S}{2} \left(1 + e^{2\lambda SN}\right)
\]
and
\[
\lim_{K \to +\infty} S_{N,K}(n_1, \ldots, n_K) = \frac{S}{2} \left(1 + \frac{e^{2\lambda SN} - 1}{2\lambda SN}\right).
\]

6 Market Impact and Option Pricing

6.1 Pricing equation

We consider the framework of covered options, hence we start from a delta-hedged portfolio. Let us assume that the stock price \( S \) moves initially by \( dS \) such that \((dS_n)_{n \in \mathbb{N}}\) is a regular \( \phi \)-market impact scenario given by (13) with
\[
dS = S(\nu dt + \sigma dW_t),
\]
where \((W_t)_{t \geq 0}\) is a Brownian motion. By following the hedging strategy presented above we move the spot from \( S \) to \( S + \tilde{dS} \) where \( dS \) represents the cumulative market impact at the end of the re-hedging procedure
\[
\tilde{dS} := \sum_{n=0}^{+\infty} dS_n,
\]
hence from (16) we have
\[
\tilde{dS} = \frac{dS}{1 - \phi} + \frac{1}{S} \left(1 + \zeta\phi\right) \sum_{n=0}^{+\infty} \left(\sum_{k=0}^{n} dS_k\right) dS_n + \frac{1}{S^2 \left(1 - \phi\right)} \sum_{n=0}^{+\infty} \left(\sum_{k=0}^{n} dS_k\right)^2 dS_n,
\]
which can be rewritten
\[
\tilde{dS} = \frac{dS}{1 - \phi} + \frac{\mu}{S^2} (dS)^2 + o((dS)^2),
\]
where \( \mu \) is only a function of the parameter \( \phi \). Plugging equation (30) in the previous equation leads to
\[
\tilde{dS} = \frac{dS}{1 - \phi} + \mu \sigma^2 S dt + o(dt),
\]

as \((dS)^2 = \sigma^2 S^2 dt + o(dt)\). This gives at the leading order
\[
\tilde{d}S = \frac{dS}{1 - \phi} + \tilde{\nu} S dt + o(dt).
\]

(33)

The value \(V\) of the hedging portfolio containing \(\Delta(t, S)\) stocks at \(t\) evolves as
\[
dV = \Delta \tilde{d}S + R
\]
as \(S\) moves to \(S + \tilde{d}S\) with
\[
R = N \times (\text{Final price of the stocks bought} - \text{Average execution price})
\]

\[
= N \times \left( S + \sum_{n=0}^{+\infty} dS_n - \sum_{n=0}^{+\infty} \Gamma dS_n \left( S + \sum_{k=0}^{n} dS_k \right) \right)
\]

\[
= N \times \left( \sum_{n=0}^{+\infty} dS_n - \sum_{n=0}^{+\infty} \Gamma dS_n \left( \sum_{k=0}^{n} dS_k \right) \right)
\]

\[N = \Gamma \tilde{d}S\] being the number of stocks bought during the re-hedging procedure. As \(dS \to 0\), we have that \(\sup_{n \in \mathbb{N}} |dS_n| \to 0\). Besides the proof given of Theorem 1 shows that for \(n\) large enough there exists \(r \in (0, 1)\) such that \(|dS_{n+1}| < r|dS_n|\), hence we can apply Remark 1 and use the results stated in Theorem 4. When \(\lambda(t, S) \equiv \lambda\) we have that

Final price of the stocks bought = \(S + S(e^{\lambda N} - 1)\)

and

Average execution price = \(S + S \left( \frac{e^{\lambda N} - 1}{\lambda N} - 1 \right)\),

giving at the leading order
\[
R = \frac{1}{2} \lambda S N^2.
\]
The same can be done when \(\lambda(t, S) \equiv \lambda S\) and gives

Final price of the stocks bought = \(S + \frac{S}{2} (e^{2\lambda SN} - 1)\)

and

Average execution price = \(S + \frac{S}{2} \left( \frac{e^{2\lambda SN} - 1}{2\lambda SN} - 1 \right)\),

implying also at the leading order
\[
R = \frac{1}{2} \lambda S^2 N^2.
\]
Finally one can write in any case
\[
R = \frac{1}{2} \lambda N^2 S^{1+\zeta}
\]
with \( N = \Gamma dS \). This gives
\[
dV = \Delta d\tilde{S} + \frac{1}{2} \lambda S^{1+\zeta} (\Gamma d\tilde{S})^2. \tag{34}
\]
Besides assuming that the option is sold at its fair price, we have \( dV = du \) with at the leading order, for \( S \) moving to \( S + dS \),
\[
 du = \partial_t u \, dt + \partial_s u \, d\tilde{S} + \frac{1}{2} \partial_{ss} u (d\tilde{S})^2 + o(dt). \tag{35}
\]
Therefore from equations (34) and (35) we get
\[
 \partial_t u \, dt + \frac{1}{2} (d\tilde{S})^2 [\partial_{ss} u - \lambda S^{1+\zeta} (\partial_{ss} u)^2] = o(dt). \tag{36}
\]
If we plug the spot dynamics (30) in the expression of \( d\tilde{S} \) (33), we obtain at the leading order
\[
 (d\tilde{S})^2 = \frac{\sigma^2 S^2}{(1-\phi)^2} \, dt + o(dt). \tag{37}
\]
By reinjecting (37) in (36), we obtain the pricing equation
\[
 \partial_t u + \frac{1}{2} \sigma^2 S^2 \partial_{ss} u - \frac{1}{1-\phi} = 0, \tag{38}
\]
\[
 \phi = \lambda S^{1+\zeta} \partial_{ss} u.
\]

6.2 Perfect replication

Any contingent claim can be perfectly replicated at zero cost, as long as one can exhibit a solution to the pricing equation (38). This implies that we need to study the parabolicity of the given pricing equation. Furthermore we have established that only market impact scenarios admissible from a trading perspective have to be considered which leads according to Theorem 1 to the constraint
\[
 \sup_{(t,s) \in [0,T] \times \mathbb{R}_+} \lambda S^{1+\zeta} \partial_{ss} u < 1, \tag{39}
\]
with \( T \) the maturity of the option. In fact we have the following result

**Theorem 7.** There holds the two following propositions:

(i) The non-linear backward partial differential operator
\[
 \partial_t + \frac{1}{2} \sigma^2 S^2 \frac{\partial_{ss} u}{1-\lambda S^{1+\zeta} \partial_{ss} u}.
\]
is parabolic.

(ii) Every European style contingent claim with payoff \( \Phi \) satisfying the terminal constraint
\[
 \sup_{s \in \mathbb{R}_+} \lambda S^{1+\zeta} \partial_{ss} u < 1
\]
can be perfectly replicated via a \( \delta \)-hedging strategy given by the unique, smooth away from the maturity \( T \), solution to equation (38).
Proof. The parabolic nature of the operator is determined by the monotonicity of the function
\[ F : p \in (-\infty, 1) \mapsto \frac{p}{1-p}. \]

\( F \) is globally increasing, therefore the pricing equation is globally well-posed. Besides, given that the payoff satisfies the terminal constraint, classical results on the maximum principle for the second derivative of the solution ensure that the same constraint is satisfied globally for \( t \leq T \) which constitutes in fact the constraint (39). Hence, the perfect replication is possible. Results on maximum principle for the second derivative can be found in [Wang, 1992a] and [Wang, 1992b] for instance. A proof of this result in a more general setting is also given in [Abergel and Loeper, 2017].

### 6.3 SDE formulation

#### 6.3.1 The system of SDE

Let \((\Omega, \mathcal{F}, (\mathcal{F}_t)_{t \geq 0}, \mathbb{P})\) a filtered probability space supporting an \((\mathcal{F}_t)_{t \geq 0}\) standard Brownian motion \((W_t)_{t \geq 0}\). Considering the result established in Theorem 1, we will assume the following uniform condition:

**Assumption 2.** There exists a constant \(\varepsilon > 0\), such that for all \(t \geq 0\), \(\mathbb{P}\)-a.s.,

\[
1 - \lambda(t, S_t) S_t \Gamma_t \geq \varepsilon. \tag{40}
\]

Let us consider then the following system of stochastic differential equations:

\[
d\delta_t = a_t dt + \Gamma_t dS_t, \tag{41}
\]

\[
\frac{dS_t}{S_t} = \sigma(t, S_t) dW_t + \left( \nu(t, S_t) + \frac{\sigma^2(t, S_t) S_t \Gamma_t \left( \lambda(t, S_t) + \partial_x \lambda(t, S_t) \right)}{1 - \lambda(t, S_t) S_t \Gamma_t} \right) dt + \lambda(t, S_t) d\delta_t, \tag{42}
\]

\[
dV_t = \delta_t dS_t + \frac{1}{2} \lambda(t, S_t) S_t d\langle \delta, \delta \rangle_t, \tag{43}
\]

where \(\delta, S \) and \(V\) are three processes starting respectively from \(\delta_0, S_0\) and \(V_0\) at \(t = 0\). We set

\[
\alpha_t \equiv \alpha(t, S_t, \Gamma_t) := \frac{\tilde{\sigma}(t, S_t) \Gamma_t}{1 - \lambda(t, S_t) \Gamma_t},
\]

and

\[
\beta_t \equiv \beta(t, S_t, \Gamma_t) := \frac{\alpha_t}{1 - \lambda(t, S_t) \Gamma_t} + \frac{\Gamma_t}{1 - \lambda(t, S_t) \Gamma_t} \left( \tilde{\nu}(t, S_t) + \frac{\tilde{\sigma}^2(t, S_t) \Gamma_t \partial_x \tilde{\lambda}(t, S_t)}{1 - \lambda(t, S_t) \Gamma_t} \right),
\]

by introducing also for all \(t \in [0, T], x \in \mathbb{R}_+\),

\[
\tilde{\sigma}(t, x) := x \sigma(t, x),
\]

\[
\tilde{\nu}(t, x) := x \nu(t, x),
\]

and

\[
\tilde{\lambda}(t, x) := x \lambda(t, x).
\]

Hence the system of stochastic differential equations (41)-(42)-(43) can be rewritten

\[
d\delta_t = \alpha_t dW_t + \beta_t dt, \tag{44}
\]

\[
dS_t = \tilde{\sigma}(t, S_t) dW_t + \left( \tilde{\nu}(t, S_t) + \alpha_t (\tilde{\sigma} \partial_x \tilde{\lambda})(t, S_t) \right) dt + \tilde{\lambda}(t, S_t) d\delta_t, \tag{45}
\]

\[
dV_t = \delta_t dS_t + \frac{1}{2} \tilde{\lambda}(t, S_t) \alpha_t^2 dt. \tag{46}
\]
Theorem 8. Suppose the following assumptions hold:

- \((a_t)_{t \geq 0}\) and \((\Gamma_t)_{t \geq 0}\) are uniformly bounded adapted processes
- \((\Gamma_t)_{t \geq 0}\) satisfies uniformly the condition \((40)\)
- there exists a constant \(K > 0\), such that for all \((t, x) \in [0, T] \times \mathbb{R}\),
  \[|x\sigma(t, x)| + |x\nu(t, x)| \leq K\]
- there exists a constant \(K > 0\), such that for all \((t, x, y) \in [0, T] \times \mathbb{R} \times \mathbb{R}\),
  \[|x\sigma(t, x) - y\sigma(t, y)| + |x\nu(t, x) - y\nu(t, y)| \leq K|x - y|\]
- \((t, x) \in [0, T] \times \mathbb{R} \mapsto \lambda(t, x)\) is of class \(C^{1,2}\) and all its partial derivatives are bounded.
- \((t, x) \in [0, T] \times \mathbb{R} \mapsto x\lambda(t, x)\) has all its partial derivatives bounded.

Then there exists a unique strong solution to the system of stochastic differential equations \((44)-(45)-(46)\) starting from \((\delta_0, S_0, V_0) \in \mathbb{R}^3\) at \(t = 0\).

Proof. By plugging \((44)\) in \((45)\), we have

\[
dS_t = \left(\tilde{\sigma}(t, S_t) + \alpha_t \tilde{\lambda}(t, S_t)\right) dW_t + \left(\tilde{\nu}(t, S_t) + \alpha_t (\tilde{\sigma} \partial_x \tilde{\lambda})(t, S_t) + \beta_t \tilde{\lambda}(t, S_t)\right) dt
\]

with \(S\) starting from \(S_0 \in \mathbb{R}\). \(a(t, S_t, \Gamma_t)\) and \(b(t, S_t, \Gamma_t)\) can be expressed as a sum of terms of the form

\[
h(t, S_t, \Gamma_t) := b_t f(\tilde{\lambda}(t, S_t) \Gamma_t) g(t, S_t)
\]

where \((b_t)_{t \geq 0}\) is a uniformly bounded adapted process, \(f\) bounded Lipschitz-continous on \((-\infty, 1 - \varepsilon)\) and \(g\) bounded Lipschitz-continous in the space variable on \([0, T] \times \mathbb{R}\). For all \((t, x, y) \in [0, T] \times \mathbb{R} \times \mathbb{R}\),

\[
h(t, x, \Gamma_t) - h(t, y, \Gamma_t) = b_t \left(f(\tilde{\lambda}(t, x) \Gamma_t) g(t, x) - f(\tilde{\lambda}(t, y) \Gamma_t) g(t, y)\right)
\]

\[
= b_t \left(f(\tilde{\lambda}(t, x) \Gamma_t) - f(\tilde{\lambda}(t, y) \Gamma_t)\right) g(t, x)
\]

\[
+ b_t f(\tilde{\lambda}(t, y) \Gamma_t) (g(t, x) - g(t, y)).
\]

Therefore there exists a constant \(C_1 > 0\) such that for all \((t, x, y) \in [0, T] \times \mathbb{R} \times \mathbb{R}\),

\[
|h(t, x, \Gamma_t) - h(t, y, \Gamma_t)| \leq C_1 |x - y| \quad \mathbb{P} \text{ - a.s.}
\]

giving that there exists a constant \(C_2 > 0\) such that for all \((t, x, y) \in [0, T] \times \mathbb{R} \times \mathbb{R}\),

\[
|a(t, x, \Gamma_t) - a(t, y, \Gamma_t)| + |b(t, x, \Gamma_t) - b(t, y, \Gamma_t)| \leq C_2 |x - y| \quad \mathbb{P} \text{ - a.s.}
\]

This leads that the stochastic differential equation \((47)\) with the initial condition \(S_0 \in \mathbb{R}\) admits a unique strong solution. Therefore we deduce that the system of stochastic differential equations \((44)-(45)-(46)\) admits a unique strong solution so does the system \((41)-(42)-(43)\). \(\square\)
In what follows we will show that the system of stochastic differential equations (44)-(45)-(46) can be derived from a discrete rebalancing trading strategy taking to the limit \( n \to +\infty \), where \( n \) represent the number of auctions of the trading strategy. To this end, let us consider for all \( n \in \mathbb{N}^* \), the following discrete time rebalancing time grid \( (t^n_i)_{i \in [0,n]} \) such that

\[
0 = t^n_0 < t^n_1 < \ldots < t^n_{n-1} < t^n_n = T.
\]

with \( T > 0 \) a fixed maturity. We set for all \( n \in \mathbb{N}^* \),

\[
\Delta_n := \sup_{1 \leq i \leq n} |t^n_i - t^n_{i-1}|.
\]

Let us set \( (\delta^n_n, S^n, V^n)_{n \in \mathbb{N}^*} \) the sequence of processes defined on \([0, T]\) such that for all \( t \in [0, T] \),

\[
\delta^n_t = \sum_{k=0}^{n-1} \delta^n_k \mathbb{1}_{\{t^n_k \leq t < t^n_{k+1}\}} + \delta^n_T \mathbb{1}_{\{t = T\}},
\]

\[
S^n_t := S_0 + \sum_{k=1}^{n} \mathbb{1}_{\{t^n_{k-1} \leq t \leq t^n_k\}} \left( \int_{t^n_{k-1}}^{t^n_k} \tilde{\sigma}(s, S^n_s) \, dW_s + \int_{t^n_{k-1}}^{t^n_k} \tilde{\nu}(s, S^n_s) \, ds \right)
\]

\[
+ \sum_{k=1}^{n} \mathbb{1}_{\{t^n_k \leq t \leq T\}} (\delta^n_k - \delta^n_{k-1}) \tilde{\lambda}(t^n_k, S^n_{t^n_k}).
\]

\[
V^n_t := V_0 + \sum_{k=1}^{n} \mathbb{1}_{\{t^n_{k-1} \leq t \leq t^n_k\}} \delta^n_{k-1} (S^n_{t^n_k} - S^n_{t^n_{k-1}})
\]

\[
+ \sum_{k=1}^{n} \mathbb{1}_{\{t^n_k \leq t \leq T\}} \left[ \frac{1}{2} (\delta^n_k - \delta^n_{k-1})^2 \tilde{\lambda}(t^n_k, S^n_{t^n_k}) + \delta^n_{k-1} (\delta^n_k - \delta^n_{k-1}) \tilde{\lambda}(t^n_k, S^n_{t^n_k}) \right].
\]

**Theorem 9.** Suppose the assumptions of Theorem 8 hold. Let \( X := (\delta, S, V) \) the unique strong solution of the system of stochastic differential equations (44)-(45)-(46) on \([0, T]\) starting from \((\delta_0, S_0, V_0) \in \mathbb{R}^3\) at \( t = 0 \) and \((X^n)_{n \in \mathbb{N}^*} := (\delta^n, S^n, V^n)_{n \in \mathbb{N}^*}\) defined as in (64)-(65)-(73). Assume that \( \Delta_n = O \left( \frac{1}{n} \right) \). Then there exists a constant \( C > 0 \) such that for all \( n \in \mathbb{N}^* \),

\[
\sup_{t \in [0, T]} \mathbb{E} \left[ \|X_t - X^n_t\|^2_2 \right] \leq C \Delta_n.
\]

In particular we have that

\[
X^n \xrightarrow{\mathbb{P}, \mathbb{L}^2, n \to +\infty} X.
\]

Furthermore if \( \sum_{n=1}^{+\infty} \Delta_n < +\infty \), we have also that

\[
X^n \xrightarrow{\mathbb{P}_{-a.s.}, \mathbb{L}^{2, \mathbb{P}}, n \to +\infty} X.
\]

**Proof.** The first convergence result is a straightforward application of Propositions A.7.1, A.7.2 and A.7.3. Assume now that \( \sum_{n=1}^{+\infty} \Delta_n < +\infty \). Let \( t \in [0, T] \), we have for all \( n \in \mathbb{N}^* \),

\[
\mathbb{E} \left[ \|X_t - X^n_t\|^2_2 \right] \leq C \Delta_n.
\]
\[
\sum_{n=1}^{+\infty} E \left[ \| X_t - X_t^n \|_2^2 \right] = E \left[ \sum_{n=1}^{+\infty} \| X_t - X_t^n \|_2^2 \right] < +\infty,
\]

which implies that
\[
\sum_{n=1}^{+\infty} \| X_t - X_t^n \|_2^2 < +\infty \quad \mathbb{P} \text{-a.s.}
\]

and
\[
\lim_{n \to +\infty} \| X_t - X_t^n \|_2 = 0 \quad \mathbb{P} \text{-a.s.}
\]

**Corollary 1.** Suppose the assumptions of Proposition 8 hold. Let \( X := (\delta, S, V) \) the unique strong solution of the system of stochastic differential equations (44)-(45)-(46) on \([0, T]\) starting from \((\delta_0, S_0, V_0) \in \mathbb{R}^3\) at \( t = 0 \) and \((X^n)_{n \in \mathbb{N}^*} := (\delta^n, S^n, V^n)_{n \in \mathbb{N}^*}\) defined as in (64)-(65)-(73). Assume that one of the two following conditions hold:

(i) There exists \( \varepsilon > 0 \) such that \( \Delta_n = O \left( \frac{1}{n^{1+\varepsilon}} \right) \).

(ii) \((\Delta_n)_{n \in \mathbb{N}^*}\) is a non-increasing sequence such that \( \sum_{n=1}^{+\infty} \Delta_n < +\infty \).

Then we have
\[
X^n \xrightarrow{n \to +\infty} \mathbb{P} \text{-a.s.} \xrightarrow{L^2, \mathbb{P}, L} X.
\]

**Proof.** If we suppose (i), using the results on Riemann series and Theorem 9 leads to the conclusion. Let us suppose now (ii) and let us show that this implies that \( \Delta_n = o \left( \frac{1}{n} \right) \) when \( n \to +\infty \). Let \( n \in \mathbb{N}^* \), we have
\[
\sum_{k=1}^{2n} \Delta_k - \sum_{k=1}^{n} \Delta_k = \sum_{k=n+1}^{2n} \Delta_k \geq n\Delta_{2n},
\]

hence \( \lim_{n \to +\infty} n\Delta_{2n} = 0 \). Besides we have also
\[
(2n + 1)\Delta_{2n+1} \leq (2n + 1)\Delta_{2n} \leq 2n\Delta_{2n} + \Delta_{2n}.
\]

Therefore we have
\[
\lim_{n \to +\infty} 2n\Delta_{2n} = \lim_{n \to +\infty} (2n + 1)\Delta_{2n+1} = 0,
\]

which implies that \( \lim_{n \to +\infty} n\Delta_n = 0 \).

The conclusion is now a straightforward application of Theorem 9. \( \square \)
6.3.2 The pricing equation

In option theory pricing the establishment of the valuation partial differential equation is often connected to the replication problem which consists in finding a self-financed strategy and an initial wealth $V_0$ such that $\Phi(S_T) = V_T$, $\mathbb{P}$–a.s. where $\Phi$ is a terminal payoff. Let $(\delta,S,V)$ a strong solution to the system of stochastic differential equations (44)-(45)-(46), which can take the form given in (41)-(42)-(43), and $u \in C^{1,2}([0,T] \times \mathbb{R})$ a smooth function such that $u(T,\cdot) = \Phi$. The absence of arbitrage opportunities implies that for all $t \in [0,T]$, $\mathbb{P}$–a.s., $u(t,S_t) = V_t$. We consider the strategy given by $\epsilon(t,S_t) = \partial_s u(t,S_t)$, hence we have $\Gamma_t = \partial_{ss} u(t,S_t)$, $\mathbb{P}$–a.s. by the unicity of the Ito decomposition. Applying Ito’s lemma to $u$ gives

$$du(t,S_t) = \partial_t u(t,S_t)dt + \partial_s u(t,S_t)dS_t + \frac{1}{2} \partial_{ss} u(t,S_t)d\langle S,S \rangle_t,$$  \hfill (51)

besides we have also

$$dV_t = \partial_s u(t,S_t)dS_t + \frac{1}{2}\lambda(t,S_t)\Gamma_t^2 d\langle S,S \rangle_t.$$ \hfill (52)

By combining (41) and (42), we obtain

$$dS_t = \frac{\sigma(t,S_t)S_t}{1-\lambda(t,S_t)S_t\Gamma_t}dW_t + \frac{\mu_t S_t + a_t \lambda(t,S_t)}{1-\lambda(t,S_t)S_t\Gamma_t}dt$$

with

$$\mu_t := \nu(t,S_t) + \frac{\sigma^2(t,S_t) \Gamma_t (\lambda(t,S_t) + S_t \partial_s \lambda(t,S_t))}{1-\lambda(t,S_t)S_t\Gamma_t}.$$ \hfill (53)

hence

$$d\langle S,S \rangle_t = \frac{\sigma^2(t,S_t)S_t^2}{(1-\lambda(t,S_t)S_t\Gamma_t)^2}dt,$$

which reads in the equality between (51) and (52)

$$\partial_t u(t,S_t) + \frac{1}{2} \sigma^2(t,S_t)S_t^2 \Gamma_t \frac{1}{1-\lambda(t,S_t)S_t\Gamma_t} = 0, \mathbb{P} – a.s..$$

Therefore $u \in C^{1,2}([0,T] \times \mathbb{R})$ is a solution of

$$\partial_t u + \frac{1}{2} \sigma^2_s s^2 \sigma_{ss} u \frac{1}{1-\phi} = 0,$$ \hfill (54)

$$\phi(t,s) = \lambda(t,s)s \partial_{ss} u(t,s),$$ \hfill (55)

$$1 - \phi \geq \varepsilon,$$ \hfill (56)

$$u(T,\cdot) = \Phi.$$ \hfill (57)

7 The Market Impact of Hedging Metaorders

In [Said et al., 2018] the authors define a metaorder as a large trading order split into small pieces and executed incrementally the same day by the same agent on the same stock and all having the same direction (buy or sell). This and Proposition 3 motivates the following definition:

**Definition 8.** Let $(u_n)_{n \in \mathbb{N}}$ a regular $\phi$–market impact scenario. The market impact scenario $(u_n)_{n \in \mathbb{N}}$ is said to be a metaorder if, and only if, $\phi \in (0,1)$. We will also refer to these metaorders as hedging metaorders.
7.1 Dynamics of Hedging Metaorders

Let us consider an hedging metaorder \((dS_n)_{n \in \mathbb{N}}\). The proofs given to establish Theorem 1 have shown that there exists \(r \in (0, 1)\) such that for all \(n \in \mathbb{N}\), \(|dS_{n+1}| \leq r \times |dS_n|\). Without loss of generality we will consider for now in the rest of the section that \((dS_n)_{n \in \mathbb{N}}\) is a buy metaorder i.e. \(dS_n > 0\) for any \(n \in \mathbb{N}\). Let us set for all \(n \in \mathbb{N}\),

\[
I_n := \sum_{k=0}^{n} dS_k
\]  

the temporary market impact after \(n\) trades. As the sequence \((dS_n)_{n \in \mathbb{N}}\) is strictly non-increasing, the plot \((n, I_n)_{n \in \mathbb{N}}\) has a concave non-decreasing shape reaching a plateau as \(n \to +\infty\) since we have that \(\lim_{n \to +\infty} dS_n = 0\). In order to illustrate those ideas let us plot the dynamics of an hedging metaorder in the case that the \(dS_{n+1} = r \times dS_n\) for any \(n \in \mathbb{N}\) with \(r = 0.8\) and \(dS_1 = 5\) bps.

![Graph showing the dynamics of hedging metaorders](image)

7.2 Immediate Impact and Size of the Hedging Metaorder

Let us consider an hedging metaorder \((dS_n)_{n \in \mathbb{N}}\) and recall that the number of shares executed during the hedging metaorder is given by

\[
N = \Gamma \sum_{n=0}^{+\infty} dS_n.
\]

This leads to the following linear relation

\[
I = \Gamma^{-1} N,
\]
7.3 Relaxation of Hedging Metaorders

Let us consider an hedging metaorder \((dS_n)_{n\in\mathbb{N}}\). By Proposition 3 we can consider that \(N(dS) = +\infty\). We have already established that at the leading order

\[
R = \sum_{n=0}^{+\infty} \Gamma dS_n \times \left( \sum_{n=0}^{+\infty} dS_n - \frac{\sum_{n=0}^{+\infty} \Gamma dS_n \left( \sum_{k=0}^{n} dS_k \right)}{\sum_{n=0}^{+\infty} \Gamma dS_n} \right) = \frac{1}{2} \lambda \left( \sum_{n=0}^{+\infty} \Gamma dS_n \right)^2 S^{1+\zeta},
\]

leading to

\[
\sum_{n=0}^{+\infty} \Gamma dS_n \left( \sum_{k=0}^{n} dS_k \right) = \left( 1 - \frac{\phi}{2} \right) \sum_{n=0}^{+\infty} dS_n.
\]

It has been shown in several empirical works that the market impact of metaorders possesses two distinct phases: A temporary impact as a consequence of the execution of the order followed by a relaxation phenomenon leading to a permanent impact. The relaxation phenomenon has been studied from an empirical point of view in stocks market [Bershova and Rakhlin, 2013] [Baery et al., 2015] [Said et al., 2018] and with a theoretical insight in [Bouchaud et al., 2004] [Gatheral et al., 2011] and [Farmer et al., 2013] for instance. Recently the same has been done empirically concerning options market [Said et al., 2019]. Let us consider \((dS_n)_{n\in\mathbb{N}}\) a metaorder starting from \(dS \neq 0\), hence \(N(dS) = +\infty\). In the terminology of metaorders let us denote by

\[
\mathcal{I} := \sum_{n=0}^{+\infty} dS_n
\]

as the temporary impact of the metaorder \((dS_n)_{n\in\mathbb{N}}\). We will denote by \(I\) the permanent impact of the metaorder \((dS_n)_{n\in\mathbb{N}}\). According to the Fair Pricing condition – predicted theoretically in [Farmer et al., 2013] and validated empirically in equity [Said et al., 2018] and options [Said et al., 2019] market – the permanent impact \(I\) satisfies the following identity:

\[
S + I = \frac{\sum_{n=0}^{+\infty} \Gamma dS_n \times (S + \mathcal{I}_n)}{\sum_{n=0}^{+\infty} \Gamma dS_n},
\]

where for all \(n \in \mathbb{N}\), \(\mathcal{I}_n := \sum_{k=0}^{n} dS_k\) as defined in (58), giving that

\[
I = \frac{\sum_{n=0}^{+\infty} \Gamma dS_n \times \mathcal{I}_n}{\sum_{n=0}^{+\infty} \Gamma dS_n}.
\]

The fair pricing identity (60), introduced in [Farmer et al., 2013], is in fact a non-arbitrage condition as it states that the final price – after the price reversion of the metaorder – reaches
a level such that it equals to the volume-weighted average price of the metaorder. The fair
pricing identity (61) reads that the permanent impact is equal to the volume-weighted average
temporary impacts of the metaorder. Hence we have shown that:

**Theorem 10.**

\[ \frac{I}{L} = 1 - \frac{\phi}{2} \]  

(62)
giving the level of the relaxation phenomenon of the metaorder. Hence

\[ \frac{1}{2} \leq \frac{I}{L} \leq 1. \]  

(63)

Theorem 10 connects directly the intensity \( \phi \) of the hedging metaorder with the intensity of
the price reversion after the end of the metaorder. Particularly it states that the more the intensity
is the more the relaxation will be. According to recent empirical and theoretical works
[Bershova and Rakhlin, 2013] [Farmer et al., 2013] [Said et al., 2018] [Bucci et al., 2019b], we
have that \( \langle 1 - \frac{1}{2} \phi \rangle_{\text{metaorders}} = \frac{2}{3} \) for intraday metaorders where \( \langle \ldots \rangle_{\text{metaorders}} \) stand for a
mean value over all the metaorders. In [Bucci et al., 2019b] the authors precise that if we study
the price reversion \( \sim 50 \) days after the end of the metaorder we have approximately \( \frac{I}{L} \approx 0.5 \) also
in agreement with (62). Nevertheless in our framework the limit case \( \frac{I}{L} \rightarrow \frac{1}{2} \) corresponds to the
limit case when \( \phi \rightarrow 1 \) i.e. when the market impact of the hedging metaorder become bigger
and bigger. Hence the lower bound of (63) can be attained in the case of very large metaorders.
This is in favor that by taking in consideration very large metaorders whom the execution can
last several days as in [Bucci et al., 2019b], we can find a mean-value that can be closed to 1/2.

8 Conclusion

In this paper we have presented a perturbation theory of market impact that connects option
pricing theory with market microstructure empirical findings. From the option pricing point
of view our model appears to be an extension of the model presented in [Loeper, 2018] in
which we study the hedging process. Furthermore we have introduced what we have called the
hedging metaorders to establish a connection between option hedging and market microstructure
metaorders. Particularly we have shown in our framework that our hedging metaorders obey
to linear market impact in the size of the metaorder and possess a relaxation factor in \([1/2, 1]\)
directly connected to their intensity characterized by the parameter \( \phi \).
References

A Proofs

A.1 Proof of Theorem 1

The proof of Theorem 1 is a consequence of the following propositions (see Propositions A.1.1, A.1.2, A.1.3 and A.1.4). It gives an equivalent criterion on the parameter $\phi$ for a market impact scenario to be admissible. We will establish that a market impact scenario is admissible from a trading perspective if, and only if, $\phi \in (-\infty, 1)$.

**Proposition A.1.1.** Let $(u_n)_{n \in \mathbb{N}}$ an $\phi$–market impact scenario. If $\phi \geq 1$, then $(u_n)_{n \in \mathbb{N}}$ is not admissible from a trading perspective.

*Proof.* Let $R > 0$ and $x \in (0, R)$. Hence for all $n \in \mathbb{N}$, $u_n(x) > 0$ which implies that for all $n \in \mathbb{N}$, $s_n(x) > 0$. Thus for all $n \in \mathbb{N}$,

$$-s_n(x) - S \leq 0$$

and

$$\phi \left( 1 + \frac{s_n(x)}{S} \right)^{1+\zeta} u_n(x) \geq 0,$$

which gives for all $n \in \mathbb{N}$,

$$u_{n+1}(x) = \phi \left( 1 + \frac{s_n(x)}{S} \right)^{1+\zeta} u_n(x) \geq \phi u_n(x).$$

In that case the series $\sum_{n \geq 0} u_n(x)$ diverges and $\sum_{n=0}^{+\infty} u_n(x) = +\infty$. \qed

**Proposition A.1.2.** Let $(u_n)_{n \in \mathbb{N}}$ an $\phi$–market impact scenario. If $\phi \in [0, 1)$, then $(u_n)_{n \in \mathbb{N}}$ is admissible from a trading perspective.

*Proof.* When $\phi = 0$, for all $n \in \mathbb{N}$, $u_n = 0$ and $(u_n)_{n \in \mathbb{N}}$ is obviously admissible from a trading perspective. We consider now the case $\phi \in (0, 1)$. Let $r \in (\phi, 1\wedge 4\phi)$, $R = (1-r)S \left( \sqrt{\frac{r}{\phi}} - 1 \right)$ and $x \in [-R, R]$. Set $A(x) = \left\{ n \in \mathbb{N} \mid s_n(x) = -S \right\}$.

- If $A(x) \neq \emptyset$, $A(x)$ has a least element $n_0(x)$ and for all $n > n_0(x)$, $u_n(x) = 0$. This gives the absolute convergence of the series $\sum_{n \geq 0} u_n(x)$.

- Let us suppose $A(x) = \emptyset$, hence for all $n \in \mathbb{N}$, $\phi \left( 1 + \frac{s_n(x)}{S} \right)^{1+\zeta} u_n(x) \geq -s_n(x) - S$ and for all $n \in \mathbb{N}$, $u_{n+1}(x) = \phi \left( 1 + \frac{s_n(x)}{S} \right)^{1+\zeta} u_n(x)$. Let us show by induction that for all $n \in \mathbb{N}$, $|u_{n+1}(x)| \leq r|u_n(x)|$.

  - If $n = 0$, $|u_1(x)| = \phi \left| 1 + \frac{x}{S} \right|^{1+\zeta} |u_0(x)|$ and $|x| \leq R < S$. Thus

    $$|u_1(x)| \leq \phi \left( 1 + \frac{|x|}{S} \right)^2 |u_0(x)|$$

    with $\frac{|x|}{S} \leq \frac{|x|}{(1-r)S} \leq \sqrt{\frac{r}{\phi}} - 1$, which gives $|u_1(x)| \leq r|u_0(x)|$. 

25
Let \( n \geq 1 \) and suppose that for all \( k \in [0, n-1] \), \( |u_{k+1}(x)| \leq r|u_k(x)| \). Hence for all \( k \in [0, n] \), \( |u_k(x)| \leq r^k|x| \) and
\[
\sum_{k=0}^{n} \frac{|s_n(x)|}{S} \leq \frac{1}{S} \sum_{k=0}^{n} r^k|x| \leq \frac{|x|}{(1-r)S} \leq \sqrt{\frac{r}{\phi}} - 1 < 1
\]
which implies
\[
|u_{n+1}(x)| = \phi \left( 1 + \frac{s_n(x)}{S} \right)^{1+\zeta} |u_n(x)| \leq \phi \left( 1 + \frac{|s_n(x)|}{S} \right)^2 |u_n(x)| \leq r|u_n(x)|.
\]
Thus for all \( n \in \mathbb{N} \), \( |u_{n+1}(x)| \leq r|u_n(x)| \) leading to the absolute convergence of the series \( \sum_{n\geq0} u_n(x) \).

Finally for all \( x \in [-R, R] \), \( \sum_{n\geq0} u_n(x) \) converges absolutely.

\[\square\]

**Proposition A.1.3.** Let \((u_n)_{n\in\mathbb{N}}\) an \( \phi \)-market impact scenario. If \( \phi \in (-1, 0) \), then \((u_n)_{n\in\mathbb{N}}\) is admissible from a trading perspective.

**Proof.** Let \( r \in (|\phi|, 1 \wedge 4|\phi|) \), \( R = S \left( \sqrt{\frac{r}{|\phi|}} - 1 \right) \) and \( x \in [-R, R] \). \( \sum_{n\geq0} u_n(x) \) is an alternating series and for all \( n \in \mathbb{N} \), \( |s_n(x)| \leq |x| \leq R < S \). Set \( \mathcal{A}(x) = \left\{ n \in \mathbb{N} \mid s_n(x) = -S \right\} \).

- If \( \mathcal{A}(x) \neq \emptyset \), \( \mathcal{A}(x) \) has a least element \( n_0(x) \) and for all \( n > n_0(x) \), \( u_n(x) = 0 \). This gives the absolute convergence of the series \( \sum_{n\geq0} u_n(x) \).

- Let us suppose \( \mathcal{A}(x) = \emptyset \), hence for all \( n \in \mathbb{N} \), \( \phi \left( 1 + \frac{s_n(x)}{S} \right)^{1+\zeta} u_n(x) \geq -s_n(x) - S \) and for all \( n \in \mathbb{N} \), \( u_{n+1}(x) = \phi \left( 1 + \frac{s_n(x)}{S} \right)^{1+\zeta} u_n(x) \). We have for all \( n \in \mathbb{N} \),
\[
|u_{n+1}(x)| \leq |\phi| \left( 1 + \frac{s_n(x)}{S} \right)^2 |u_n(x)|
\]
and
\[
|\phi| \left( 1 + \frac{s_n(x)}{S} \right)^2 \leq |\phi| \left( 1 + \frac{|x|}{S} \right)^2 \leq r.
\]
Thus for all \( n \in \mathbb{N} \), \( |u_{n+1}(x)| \leq r|u_n(x)| \) which gives the absolute convergence of the series \( \sum_{n\geq0} u_n(x) \).

Finally for all \( x \in [-R, R] \), \( \sum_{n\geq0} u_n(x) \) converges absolutely.

\[\square\]

**Proposition A.1.4.** Let \((u_n)_{n\in\mathbb{N}}\) an \( \phi \)-market impact scenario. If \( \phi \in (-\infty, -1] \), then \((u_n)_{n\in\mathbb{N}}\) is admissible from a trading perspective.

**Proof.** Let \( x \in \mathbb{R} \), the case \( x = 0 \) being trivial let us consider now \( x \neq 0 \). Without loss of generality let us assume \( x > 0 \), the proof would be similar for \( x < 0 \). As \( \phi < 0 \), \( \sum_{n\geq0} u_n(x) \) is an alternating series. Set
\[
\mathcal{A}(x) = \left\{ n \in \mathbb{N} \mid s_n(x) = -S \right\}.
\]

- If \( \mathcal{A}(x) \neq \emptyset \) it has a least element denoted by \( n_0(x) \). Hence for all \( n \geq n_0(x) \), \( u_n(x) = 0 \) and the series \( \sum_{n\geq0} u_n(x) \) converges absolutely.
A.2 Proof of Proposition 2

Let us suppose $\mathcal{A}(x) \neq \emptyset$. Hence for all $n \in \mathbb{N}$, $\phi \left( 1 + \frac{s_n(x)}{S} \right)^{1+\zeta} u_n(x) \geq -s_n(x) - S$ and for all $n \in \mathbb{N}$, $u_{n+1}(x) = \phi \left( 1 + \frac{s_n(x)}{S} \right)^{1+\zeta} u_n(x)$. Let

$$ B(x) = \left\{ n \in \mathbb{N} \mid s_n(x) < -S + \frac{S}{\phi^{1/(1+\zeta)}} \right\}. $$

Let us assume $B(x) = \emptyset$, hence for all $n \in \mathbb{N}$, $s_n(x) \geq -S + \frac{S}{\phi^{1/(1+\zeta)}}$. As $x \neq 0$, for all $n \in \mathbb{N}$, $u_n(x) \neq 0$ and $\frac{|u_{n+1}(x)|}{|u_n(x)|} = |\phi| \left( 1 + \frac{s_n(x)}{S} \right)^{1+\zeta}$ implying that $|u_{n+1}(x)| \geq |u_n(x)|$.

Hence $(s_{2n}(x))_{n \in \mathbb{N}}$ is a non-decreasing real valued sequence and $(s_{2n+1}(x))_{n \in \mathbb{N}}$ is non-increasing. The sequence $(s_n(x))_{n \in \mathbb{N}}$ being bounded by Assumption 1, $(s_{2n}(x))_{n \in \mathbb{N}}$ and $(s_{2n+1}(x))_{n \in \mathbb{N}}$ are convergent. Let $l(x) = \lim_{n \to +\infty} s_{2n+1}(x)$ and $l'(x) = \lim_{n \to +\infty} s_{2n}(x)$. As $l(x) < 0$ and $l'(x) > 0$, we have $l(x) < l'(x)$. Besides the sequence $(|u_n(x)|)_{n \in \mathbb{N}}$ is convergent and $\lim_{n \to +\infty} |u_n(x)| = l'(x) - l(x) > 0$, hence $\lim_{n \to +\infty} \frac{|u_{2n+1}(x)|}{|u_{2n}(x)|} = 1$. We have also for all $n \in \mathbb{N}$,

$$ \frac{|u_{2n+1}(x)|}{|u_{2n}(x)|} = |\phi| \left( 1 + \frac{s_{2n}(x)}{S} \right)^{1+\zeta} $$

which gives

$$ \lim_{n \to +\infty} \frac{|u_{2n+1}(x)|}{|u_{2n}(x)|} = |\phi| \left( 1 + \frac{l'(x)}{S} \right)^{1+\zeta}. $$

This leads to $l'(x) = -S + \frac{S}{\phi^{1/(1+\zeta)}} \leq l(x)$ which implies a contradiction. Thus $B(x)$ is a non empty subset of $\mathbb{N}$ and has a least element $n_1(x)$. Without loss of generality let us suppose that $n_1(x)$ is odd hence we can write $n_1(x) = 2k(x) + 1$ with $k(x) \in \mathbb{N}$. Set

$$ C(x) = \left\{ n \in \mathbb{N} \mid s_n(x) \lor s_{n+1}(x) < -S + \frac{S}{\phi^{1/(1+\zeta)}} \right\}. $$

If $C(x) = \emptyset$ then $(s_{2n}(x))_{n \geq k(x)}$ and $(s_{2n+1}(x))_{n \geq k(x)}$ are two sequences non-increasing bounded from below. Thus $(s_{2n}(x))_{n \geq k(x)}$ and $(s_{2n+1}(x))_{n \geq k(x)}$ are convergent. Let denote by $l(x)$ and $l'(x)$ their respective limit such that $l(x) = \lim_{n \to +\infty} s_{2n+1}(x)$ and $l'(x) = \lim_{n \to +\infty} s_{2n}(x)$. As $l(x) < -S + \frac{S}{\phi^{1/(1+\zeta)}}$ and $-S + \frac{S}{\phi^{1/(1+\zeta)}} \leq l'(x)$ we have $l(x) < l'(x)$. As previously this leads to $l(x) = l'(x) = -S + \frac{S}{\phi^{1/(1+\zeta)}}$ which gives a contradiction. Thus $C(x)$ is a non empty subset of $\mathbb{N}$ and has a least element $n_2(x) \geq n_1(x)$ since $C(x) \subset B(x)$. For all $n > n_2(x)$, $\frac{|u_{n+1}(x)|}{|u_n(x)|} = |\phi| \left( 1 + \frac{s_{n_2}(x)}{S} \right)^{1+\zeta} < 1$.

Thus the series $\sum_{n \geq 0} u_n(x)$ is absolutely convergent for any $x \in \mathbb{R}$. $\square$

A.2 Proof of Proposition 2

Proof. Let $R' > 0$ such that $(-R', R') \subset (-S, +\infty)$. Besides by Theorem 2 there exists also $R'' > 0$ such that for all $x \in (-R'', R'')$, $\sum_{n \geq 0} u_n(x)$ converges absolutely. Let $R = R' \wedge R''$, for all $x \in (-R, R)$, $N(x) \geq 1$. 27
• When $N(x) < +\infty$, for all $n \geq N(x)$, $s_n(x) = -S$ and for all $n \geq N(x) + 1$, $u_n(x) = 0$.

Hence for all $n \in \mathbb{N}$, $u_{n+1}(x) = \phi \left( 1 + \frac{s_n(x)}{S} \right)^{1+\zeta} u_n(x)$.

• When $N(x) = +\infty$, for all $n \in \mathbb{N}$, $\phi \left( 1 + \frac{s_n(x)}{S} \right)^{1+\zeta} u_n(x) \geq -s_n(x) - S$ and for all $n \in \mathbb{N}$, $u_{n+1}(x) = \phi \left( 1 + \frac{s_n(x)}{S} \right)^{1+\zeta} u_n(x)$.

In any case for all $n \in \mathbb{N}$, $u_{n+1}(x) = \phi \left( 1 + \frac{(1+\zeta) s_n(x)}{S} + \frac{\zeta s_n^2(x)}{S^2} \right) u_n(x)$. This implies

\[
\frac{N(x)}{n=1} u_n(x) = \phi \frac{N(x)}{n=0} u_n(x) + \frac{(1+\zeta) \phi}{S} \frac{N(x)}{n=0} s_n(x) u_n(x) + \frac{\phi}{S} \frac{N(x)}{n=0} s_n^2(x) u_n(x)
\]

\[
\frac{N(x)}{n=0} u_n(x) = x + \phi \frac{N(x)}{n=0} u_n(x) + \frac{(1+\zeta) \phi}{S} \frac{N(x)}{n=0} s_n(x) u_n(x) + \frac{\phi}{S} \frac{N(x)}{n=0} s_n^2(x) u_n(x)
\]

\[
(1-\phi) \frac{N(x)}{n=0} u_n(x) = x + \frac{(1+\zeta) \phi}{S} \frac{N(x)}{n=0} s_n(x) u_n(x) + \frac{\phi}{S} \frac{N(x)}{n=0} s_n^2(x) u_n(x)
\]

which finally gives

\[
\frac{N(x)}{n=0} u_n(x) = \frac{x}{1-\phi} + \frac{1}{S} \frac{(1+\zeta) \phi}{1-\phi} \frac{N(x)}{n=0} s_n(x) u_n(x) + \frac{1}{S} \frac{\phi}{1-\phi} \frac{N(x)}{n=0} s_n^2(x) u_n(x).
\]

A.3 Proof of Proposition 3

Proof.

• $\phi = 0$, in that case for all $x \in \mathbb{R}$, $N(x) = +\infty$.

• $|\phi| \in (0, 1)$, let $r \in (|\phi|, 1 \wedge \frac{2}{|\phi|})$, $R = (1-r)S \left( \sqrt{\frac{p}{|\phi|}} - 1 \right)$ and $x \in [-R, R]$. Let us show by induction that for all $n \in \mathbb{N}$, $|u_{n+1}(x)| \leq r|u_n(x)|$.

• If $n = 0$, $|u_1(x)| = |\phi| \left| 1 + \frac{x}{S} \right|^{1+\zeta} |u_0(x)|$ and $|x| \leq R \leq S$. Thus

\[
|u_1(x)| \leq |\phi| \left( 1 + \frac{|x|}{S} \right)^2 |u_0(x)|
\]

with $\frac{|x|}{S} \leq \frac{|x|}{1-r} \leq \sqrt{\frac{r}{|\phi|}} - 1$, which gives $|u_1(x)| \leq r|u_0(x)|$.

• Let $n \geq 1$ and suppose that for all $k \in [0, n-1]$, $|u_{k+1}(x)| \leq r|u_k(x)|$. Hence for all $k \in [0, n]$, $|u_k(x)| \leq r^k |x|$ and

\[
|s_n(x)| \leq \sum_{k=0}^{n} r^k |x| \leq \frac{|x|}{(1-r)} \leq S \left( \sqrt{\frac{p}{|\phi|}} - 1 \right) < S.
\]

Besides

\[
-s_n(x) - S \leq -S + \frac{|x|}{1-r}
\]
and
\[
\left| \phi \left( 1 + \frac{s_n(x)}{S} \right)^{1+\zeta} u_n(x) \right| \leq |\phi| \left( 1 + \frac{|s_n(x)|}{S} \right)^2 |u_n(x)| \\
\leq |\phi| \left( 1 + \frac{|s_n(x)|}{S} \right)^2 |u_n(x)| \\
\leq r |u_n(x)| \\
\leq r^{n+1} |x| \\
\leq \frac{|x|}{1-r}.
\]

Hence
\[-s_n(x) - S \leq -S + \frac{|x|}{1-r} \leq -\frac{|x|}{1-r} \leq \phi \left( 1 + \frac{s_n(x)}{S} \right)^{1+\zeta} u_n(x)\]
and
\[u_{n+1}(x) = \phi \left( 1 + \frac{s_n(x)}{S} \right)^{1+\zeta} u_n(x)\]
which implies
\[|u_{n+1}(x)| = |\phi| \left( 1 + \frac{s_n(x)}{S} \right)^2 |u_n(x)| \leq |\phi| \left( 1 + \frac{|s_n(x)|}{S} \right)^2 |u_n(x)| \leq r |u_n(x)|.\]

Thus for all \(x \in [-R, R]\), \(n \in \mathbb{N}\), \(|u_{n+1}(x)| \leq r |u_n(x)|\) and \(|s_n(x)| \leq S \left( \sqrt{\frac{r}{|\phi|}} - 1 \right)\) which gives the absolute convergence of the series \(\sum_{n \geq 0} u_n(x)\) with
\[
\left| \sum_{n=0}^{+\infty} u_n(x) \right| \leq S \left( \sqrt{\frac{r}{|\phi|}} - 1 \right) < S.
\]

Therefore for all \(x \in [-R, R]\), \(N(x) = +\infty\).

\[\square\]

**A.4 Proof of Proposition 4**

*Proof.* • By Theorem 2 and Proposition 3 there exists \(R > 0\) such that for all \(x \in (-R, R)\), \(N(x) = +\infty\) and \(\sum_{n \geq 0} u_n(x)\) converges absolutely. Let \(x \in (-R, R)\), by Proposition 2 we have
\[
\sum_{n=0}^{+\infty} u_n(x) = \frac{x}{1-\phi} + \frac{1}{S} \frac{(1 + \zeta)\phi}{1-\phi} \sum_{n=0}^{+\infty} s_n(x) u_n(x) + \frac{1}{S^2} \frac{\zeta\phi}{1-\phi} \sum_{n=0}^{+\infty} s_n^2(x) u_n(x) := u(x)
\]
and for all \(n \in \mathbb{N}\),
\[
\begin{cases}
  u_0(x) = x \\
  \forall n \in \mathbb{N}, \ u_{n+1}(x) = \phi \left( 1 + \frac{s_n(x)}{S} \right)^{1+\zeta} u_n(x).
\end{cases}
\]

Hence by induction for all \(n \in \mathbb{N}\), \(x \in (-R, R)\), \(u_n(x) = P_n(x)\) with \(P_n \in \mathbb{R}[X]\) and the sequence of polynomials \((P_n)_{n \in \mathbb{N}}\) satisfying the following properties:
\[
\begin{align*}
\forall n \in \mathbb{N}, & \quad P_{n+1} = \phi \left( 1 + \frac{1}{S} \sum_{k=0}^{n} P_k \right)^{1+\zeta} P_n \quad \forall n \in \mathbb{N}, \quad P_n(0) = 0.
\end{align*}
\]

The series \( \sum_{n \geq 0} u_n(x) \) being absolutely convergent is also unconditionally convergent which implies that \( \sum_{n \geq 0} u_n \) has a power series expansion on \((-R, R)\).

For all \( n \in \mathbb{N} \), \( P_n(0) = 0 \) hence there exists \( Q_n \in \mathbb{R}[X] \) such that \( P_n = XQ_n \). The sequence of polynomials \((Q_n)_{n \in \mathbb{N}}\) satisfy the following recurrence relation
\[
\begin{align*}
Q_0 &= 1 \\
\forall n \in \mathbb{N}, & \quad Q_{n+1} = \phi \left( 1 + \frac{1}{S} \sum_{k=0}^{n} P_k \right)^{1+\zeta} Q_n
\end{align*}
\]
which implies for all \( n \in \mathbb{N} \), \( Q_n(0) = \phi^n \). Besides
\[
u(x) = \frac{x}{1 - \phi} + \frac{1}{S} \frac{(1 + \zeta)\phi}{1 - \phi} \sum_{n=0}^{\infty} \left( \sum_{k=0}^{n} P_k(x) \right) P_n(x) + \frac{\zeta \phi}{1 - \phi} \sum_{n=0}^{\infty} \left( \sum_{k=0}^{n} P_k(x) \right)^2 P_n(x).
\]

Let us show that \( v(x) = \sum_{n=0}^{\infty} \left( \sum_{k=0}^{n} Q_k(0) \right) Q_n(0)x^2 + o(x^2) \) and \( w(x) = o(x^2) \) as \( x \to 0 \).

Let \( x \in \mathbb{R} \) such that \( |x| < R \land (1 - r) \sqrt{\frac{r}{|\phi|}} - 1 \) with \( r \in (|\phi|, 1 \land \frac{9}{10}|\phi|) \). As shown in Proposition 3 for all \( n \in \mathbb{N} \), \( |P_n(x)| \leq r^n|x| \) which gives for all \( n \in \mathbb{N} \), \( |Q_n(x)| \leq r^n \). Let \( x \neq 0 \), we have \( \frac{v(x)}{x^2} = \sum_{n=0}^{\infty} \left( \sum_{k=0}^{n} Q_k(x) \right) Q_n(x) \) and for all \( n \in \mathbb{N} \),
\[
\begin{align*}
\left| \left( \sum_{k=0}^{n} Q_k(x) \right) Q_n(x) \right| &\leq \left( \sum_{k=0}^{n} |Q_k(x)| \right) |Q_n(x)| \\
&\leq \left( \sum_{k=0}^{n} r^k \right) r^n \\
&\leq 1 - r^{n+1} \\
&\leq \frac{1 - r^n}{1 - r} r^n
\end{align*}
\]
and \( \sum_{n=0}^{\infty} (1 - r^{n+1}) r^n < +\infty \). This leads to \( \lim_{x \to 0} \frac{v(x)}{x^2} = \sum_{n=0}^{\infty} \left( \sum_{k=0}^{n} Q_k(0) \right) Q_n(0) \). Similarly
we have \( \lim_{x \to 0} \frac{w(x)}{x^2} = \sum_{n=0}^{+\infty} \left( \sum_{k=0}^{n} Q_k(0) \right)^2 P_n(0) = 0 \). We have also

\[
\sum_{n=0}^{+\infty} \left( \sum_{k=0}^{n} Q_k(0) \right)^2 Q_n(0) = \sum_{n=0}^{+\infty} \left( \sum_{k=0}^{n} \phi^k \right) \phi^n
\]

\[
= \sum_{n=0}^{+\infty} \frac{1 - \phi^{n+1}}{1 - \phi} \phi^n
\]

\[
= \frac{1}{1 - \phi} \sum_{n=0}^{+\infty} [\phi^n - \phi^{2n+1}]
\]

\[
= \frac{1}{1 - \phi} \left( \frac{1}{1 - \phi} - \frac{\phi}{1 - \phi^2} \right)
\]

\[
= \frac{1}{1 - \phi} \left( \frac{1}{1 - \phi} - \frac{\phi}{(1 - \phi)(1 + \phi)} \right)
\]

leading to

\[
u(x) = \frac{1}{1 - \phi} x + \frac{1}{S(1 - \phi^2)(1 + \phi)} x^2 + o(x^2) \text{ as } x \to 0.
\]

\[\square\]

**A.5 Proof of Theorem 3**

*Proof.* The final price of an \((N,K)\)-execution strategy is given by

\[
S_{N,K}(n_1, \ldots, n_K) = S \left( 1 + \sum_{k=1}^{K} \lambda^k \sum_{1 \leq i_1 < i_2 < \cdots < i_k \leq K} n_{i_1} n_{i_2} \cdots n_{i_k} \right).
\]

Using Maclaurin’s inequalities (see e.g. [Hardy et al., 1952]) we have

\[
S_{N,K}(n_1, \ldots, n_K) \leq S \left( 1 + \sum_{k=1}^{K} \frac{(\lambda N)^k}{K^k k!} \right)
\]

with equality exactly if and only if all the \(n_k\) are equal. Furthermore we have

\[
S \left( 1 + \lambda \sum_{k=1}^{K} n_k \right) \leq S_{N,K}(n_1, \ldots, n_K) \leq S \left( 1 + \sum_{k=1}^{K} \frac{(\lambda N)^k}{k!} \right),
\]

leading straightforwardly to (19). To derive (20) let us study the maximum of the following function

\[
f : \mathbb{R}^K \to \mathbb{R}
\]

\[
(x_1, \ldots, x_K) \mapsto \sum_{k=1}^{K} x_k \prod_{i=1}^{k-1} (1 + x_i)
\]

on

\[
\Lambda^* := \left\{ (x_1, \ldots, x_K) \in (\mathbb{R}_+^*)^{K} \mid \sum_{k=1}^{K} x_k = \lambda N \right\}.
\]

31
by setting for all \( k \in [1, K] \), \( x_k := \lambda n_k \). Let us consider the compact set
\[
\Lambda := \left\{ (x_1, \ldots, x_K) \in (\mathbb{R}_+)^K \mid \sum_{k=1}^K x_k = \lambda N \right\}.
\]
As the function \( f \) is continuous \( f|_\Lambda \) is bounded and reaches its upper bound, so there exists \( a \in \Lambda \) such that \( f(a) = \sup_{x \in \Lambda} f(x) \). Let us suppose that there exists \( i \in [1, K] \) such that \( a_i = 0 \).

Without loss of generality by rearranging the terms \( a_k \) we can take \( i = K \). We set
\[
k^* := \max \left\{ 1 \leq i \leq K \mid a_i > 0 \right\} < K,
\]
well-defined as \( \sum_{k=1}^K a_k = 1 \). Let \( 0 < \varepsilon < a_{k^*} \), we have that
\[
f(a_1, \ldots, a_{k^*} - \varepsilon, \varepsilon, 0, \ldots, 0) - f(a_1, \ldots, a_{k^*}, 0, \ldots, 0) = \varepsilon (a_{k^*} - \varepsilon) \prod_{i=1}^{k^*-1} (1 + a_i) > 0
\]
giving a contradiction. Hence for all \( i \in [1, K] \), \( a_i > 0 \) and \( \sup_{x \in \Lambda} f(x) = \sup_{x \in \Lambda^*} f(x) = f(a) \). Let us set
\[
g : \mathbb{R}^K \rightarrow \mathbb{R} \quad (x_1, \ldots, x_K) \mapsto \sum_{k=1}^K x_k - \lambda N
\]
hence \( \{ x \in (\mathbb{R}_+)^K \mid g(x) = 0 \} = \Lambda^* \). \( f \) and \( g \) are of class \( C^1 \), so there exists a Lagrange multiplier \( \beta \in \mathbb{R} \), such that for all \( k \in [1, K] \),
\[
\frac{\partial f}{\partial x_k}(a) = \beta \frac{\partial g}{\partial x_k}(a)
\]
which reads
\[
\prod_{1 \leq i \leq K \atop i \neq k} (1 + a_i) = \frac{\prod_{1 \leq i \leq K} (1 + a_i)}{1 + a_k} = \beta.
\]
Thus we have that \( a_1 = \cdots = a_K = \frac{\lambda N}{K} \). Noticing that
\[
1 + \sum_{k=1}^K \lambda^k \sum_{1 \leq i_1 < i_2 < \cdots < i_k \leq K} n_{i_1} n_{i_2} \cdots n_{i_k} = \prod_{k=1}^K (1 + \lambda n_k),
\]
we get that
\[
\overline{S}_{N,K}(n_1, \ldots, n_K) \leq \overline{S}_{N,K} \left( \frac{N}{K}, \ldots, \frac{N}{K} \right) \\
\leq \frac{1}{N} \sum_{k=1}^{K} \frac{N}{K} S \prod_{i=1}^{k-1} \left( 1 + \frac{\lambda N}{K} \right) \\
\leq S \frac{K-1}{K} \sum_{k=0}^{k-1} \left( 1 + \frac{\lambda N}{K} \right)^k \\
\leq S \left( 1 + \frac{\lambda N}{K} \right)^K - 1 \\
\leq S e^{\lambda N} - 1 \frac{\lambda N}{\lambda N}.
\]

Besides we have also
\[
\overline{S}_{N,K}(n_1, \ldots, n_K) \geq \frac{1}{N} \sum_{k=1}^{K} n_k S \left( 1 + \sum_{i=1}^{k-1} n_i \right) \\
\geq S + \frac{\lambda S}{N} \sum_{1 \leq i < k \leq \mathcal{K}} n_k n_l \\
\geq S + \frac{1}{2N} \lambda S \sum_{1 \leq l < \mathcal{K} \atop l \neq k} n_k n_l \\
\geq S + \frac{1}{2N} \lambda S \left( \sum_{1 \leq k, l \leq \mathcal{K}} n_k n_l - \sum_{k=1}^{K} n_k^2 \right) \\
\geq S + \frac{1}{2} \lambda S \left( N - \frac{1}{N} \sum_{k=1}^{K} n_k^2 \right) \\
\geq S + \frac{1}{2} \lambda S \left( N - \sup_{1 \leq k \leq \mathcal{K}} n_k \right)
\]
since the following inequality holds
\[
\frac{N}{K} \leq \frac{1}{N} \sum_{k=1}^{K} n_k^2 \leq \sup_{1 \leq k \leq \mathcal{K}} n_k.
\]

\[\square\]

A.6 Proof of Theorem 4

Proof. Let us notice that
\[
1 + \sum_{k=1}^{K} \lambda^k \sum_{1 \leq i_1 < i_2 < \cdots < i_k \leq \mathcal{K}} n_{i_1} n_{i_2} \cdots n_{i_k} = \prod_{k=1}^{K} (1 + \lambda n_k).
\]

33
We have
\[
0 \leq \lambda N - \ln \left( \prod_{k=1}^{\mathcal{K}} (1 + \lambda n_k) \right) = \sum_{k=1}^{\mathcal{K}} (\lambda n_k - \ln(1 + \lambda n_k)) \\
\leq \frac{\lambda^2}{2} \sum_{k=1}^{\mathcal{K}} n_k^2 \\
\leq \frac{\lambda^2 N}{2} \sup_{1 \leq k \leq \mathcal{K}} n_k \xrightarrow{K \to +\infty} 0.
\]

Hence
\[
\lim_{K \to +\infty} \left( 1 + \sum_{k=1}^{\mathcal{K}} \lambda^k \sum_{1 \leq i_1 < i_2 < \cdots < i_k \leq \mathcal{K}} n_{i_1} n_{i_2} \ldots n_{i_k} \right) = e^{\gamma \lambda N}.
\]

Besides we also have that
\[
\left| \frac{e^{\lambda N} - 1}{\lambda} - \sum_{k=1}^{\mathcal{K}} n_k \prod_{i=1}^{k-1} (1 + \lambda n_i) \right| = \left| \int_{0}^{N} e^{\lambda n} dn - \sum_{k=1}^{\mathcal{K}} n_k \prod_{i=1}^{k-1} (1 + \lambda n_i) \right| \\
\leq \int_{0}^{N} e^{\lambda n} dn - \sum_{k=1}^{\mathcal{K}} n_k e^{\lambda \sum_{i=1}^{k-1} n_i} \\
+ \sum_{k=1}^{\mathcal{K}} n_k e^{\lambda \sum_{i=1}^{k-1} n_i} - \sum_{k=1}^{\mathcal{K}} n_k e^{\sum_{i=1}^{k-1} \ln(1 + \lambda n_i)} \\
\leq \int_{0}^{N} e^{\lambda n} dn - \sum_{k=1}^{\mathcal{K}} n_k e^{\lambda \sum_{i=1}^{k-1} n_i} \\
+ \sum_{k=1}^{\mathcal{K}} n_k \left( e^{\lambda \sum_{i=1}^{k-1} n_i} - e^{\sum_{i=1}^{k-1} \ln(1 + \lambda n_i)} \right).
\]

In addition we have that,
\[
0 \leq \sum_{k=1}^{\mathcal{K}} n_k \left( e^{\lambda \sum_{i=1}^{k-1} n_i} - e^{\sum_{i=1}^{k-1} \ln(1 + \lambda n_i)} \right) \\
\leq e^{\lambda N} \sum_{k=1}^{\mathcal{K}} n_k \left( \lambda \sum_{i=1}^{k-1} n_i - \sum_{i=1}^{k-1} \ln(1 + \lambda n_i) \right) \\
\leq e^{\lambda N} \sum_{k=1}^{\mathcal{K}} n_k \frac{\lambda^2}{2} \sup_{1 \leq k \leq \mathcal{K}} n_k \\
\leq e^{\lambda N} \frac{(\lambda N)^2}{2} \sup_{1 \leq k \leq \mathcal{K}} n_k
\]

where we have used that for all \((a, b) \in [0, \lambda N]^2\), \(|e^a - e^b| \leq e^{\lambda N}|a - b|\). As
\[
\lim_{K \to +\infty} \sup_{1 \leq k \leq \mathcal{K}} |n_k| = 0,
\]
we get that
\[
\lim_{K \to +\infty} \sum_{k=1}^{\mathcal{K}} n_k \prod_{i=1}^{k-1} (1 + \lambda n_i) = \int_{0}^{N} e^{\lambda n} dn.
\]
Consequently,
\[
\lim_{K\to+\infty} \sum_{k=1}^{K} n_k \prod_{i=1}^{k-1} (1 + \lambda n_i) = e^{\lambda N} - 1.
\]

\[\square\]

A.7 Proof of Theorem 9

**Proposition A.7.1.** Suppose the assumptions of Theorem 8 hold. Let \((\delta^n)_{n\in\mathbb{N}}\) a sequence of processes defined on \([0, T]\) such that for all \(t \in [0, T]\),

\[
\delta^n_t := \sum_{i=0}^{n-1} \delta^n_{t_i} \mathbb{1}_{\{t_i \leq t < t_{i+1}\}} + \delta^n_T \mathbb{1}_{\{t = T\}}.
\]

Assume that \(\lim_{n \to +\infty} \Delta_n = 0\). Then there exists a constant \(C > 0\) such that for all \(n \in \mathbb{N}^*\),

\[
\sup_{t \in [0, T]} \mathbb{E}[|\delta_t - \delta^n_t|^2] \leq C\Delta_n.
\]

**Proof.** Let \(t \in [0, T]\), if \(t = T\), then we have \(\delta^n_T = \delta_T\). Let us take now \(t \in [t^n_{i-1}, t^n_i)\) with \(i \in \{1, n\}\).

For all \(t \in [t^n_{i-1}, t^n_i)\),

\[
\delta_t - \delta^n_t = \delta_t - \delta^n_{t^n_{i-1}} = \int_{t^n_{i-1}}^{t} \alpha_s \, dW_s + \int_{t^n_{i-1}}^{t} \beta_s \, ds.
\]

This gives by Ito’s lemma

\[
d|\delta_t - \delta^n_t|^2 = 2(\delta_t - \delta^n_{t^n_{i-1}})(\alpha_t dW_t + \beta_t dt) + \alpha_t^2 dt
\]

\[
= 2(\delta_t - \delta^n_{t^n_{i-1}})\alpha_t dW_t + [2(\delta_t - \delta^n_{t^n_{i-1}})\beta_t + \alpha_t^2] dt
\]

and for all \(t \in [t^n_{i-1}, t^n_i)\),

\[
\mathbb{E}[|\delta_t - \delta^n_{t^n_{i-1}}|^2] = 2\mathbb{E} \left[ \int_{t^n_{i-1}}^{t} (\delta_s - \delta^n_{t^n_{i-1}}) \beta_s \, ds \right] + \mathbb{E} \left[ \int_{t^n_{i-1}}^{t} \alpha_s^2 \, ds \right]
\]

\[
\leq \mathbb{E} \left[ \int_{t^n_{i-1}}^{t} |\delta_s - \delta^n_{t^n_{i-1}}|^2 \, ds \right] + \mathbb{E} \left[ \int_{t^n_{i-1}}^{t} \beta_s^2 \, ds \right] + \mathbb{E} \left[ \int_{t^n_{i-1}}^{t} \alpha_s^2 \, ds \right]
\]

\[
\leq \int_{t^n_{i-1}}^{t} \mathbb{E}[|\delta_s - \delta^n_{t^n_{i-1}}|^2] \, ds + \int_{t^n_{i-1}}^{t} (\mathbb{E}[\beta_s^2] + \mathbb{E}[\alpha_s^2]) \, ds.
\]

Therefore there exists a constant \(C_1 > 0\) such that for all \(t \in [t^n_{i-1}, t^n_i)\),

\[
\mathbb{E}[|\delta_t - \delta^n_{t^n_{i-1}}|^2] \leq C_1 \int_{t^n_{i-1}}^{t} \mathbb{E}[|\delta_s - \delta^n_{t^n_{i-1}}|^2] \, ds + C_1 \Delta_n
\]

which implies by Gronwall’s lemma, for all \(t \in [t^n_{i-1}, t^n_i)\),

\[
\mathbb{E}[|\delta_t - \delta^n_{t^n_{i-1}}|^2] \leq C_1 \Delta_n \exp(C_1(t - t^n_{i-1})) \leq \underbrace{C_1 \Delta_n \exp(C_1\Delta_n)}_{=O(\Delta_n)}
\]

35
hence there exists a constant $C_2 > 0$ such that for all $t \in [t_{i-1}^n, t_i^n]$,
\[ \mathbb{E}[(\delta_t - \delta_{t_{i-1}}^n)^2] \leq C_2 \Delta_n. \]

Let $(\tau_k^i)_{k \in \mathbb{N}}$ a non-decreasing sequence such that $\lim_{k \to +\infty} \tau_k^i = t_i^n$, by Fatou's lemma we have
\[ \mathbb{E}\left[ \liminf_{k \to +\infty} |\delta_{\tau_k^i} - \delta_{t_{i-1}}^n|^2 \right] \leq \liminf_{k \to +\infty} \mathbb{E}[|\delta_{\tau_k^i} - \delta_{t_{i-1}}^n|^2] \leq C_2 \Delta_n, \]
and
\[ \mathbb{E}\left[ \liminf_{k \to +\infty} |\delta_{\tau_k^i} - \delta_{t_{i-1}}^n|^2 \right] = \mathbb{E}\left[ \lim_{k \to +\infty} |\delta_{\tau_k^i} - \delta_{t_{i-1}}^n|^2 \right] = \mathbb{E}[|\delta_{t_i^n} - \delta_{t_{i-1}}^n|^2] \]

since $\delta$ is a continuous process. Therefore we have for all $n \in \mathbb{N}^*$, $i \in \llbracket 1, n \rrbracket$, $t \in [t_{i-1}^n, t_i^n]$,
\[ \mathbb{E}[|\delta_t - \delta_{t_i^n}|^2] \leq C_2 \Delta_n, \]
and
\[ \sup_{t \in [0, T]} \mathbb{E}[|\delta_t - \delta_{t_i^n}|^2] = \max \sup_{1 \leq i \leq n} \mathbb{E}[|\delta_t - \delta_{t_i^n}|^2]. \]

This gives that for all $n \in \mathbb{N}^*$,
\[ \sup_{t \in [0, T]} \mathbb{E}[|\delta_t - \delta_{t_i^n}|^2] \leq C_2 \Delta_n. \]

\[ \square \]

**Proposition A.7.2.** Suppose the assumptions of Theorem 8 hold. Let $(S^n)_{n \in \mathbb{N}}$ a sequence of processes defined on $[0, T]$ such that for all $t \in [0, T]$,
\[ S^n_t := S_0 + \sum_{k=1}^{n} 1_{\{t_{k-1}^n \leq t \leq T\}} \left( \int_{t_{k-1}^n}^{t_{k}^n} \tilde{\sigma}(s, S^n_s) \, dW_s + \int_{t_{k-1}^n}^{t_{k}^n} \tilde{\nu}(s, S^n_s) \, ds \right) \]
\[ + \sum_{k=1}^{n} 1_{\{t_k^n \leq t \leq T\}} (\delta_{t_k^n} - \delta_{t_{k-1}^n}) \tilde{\lambda}(t_k^n, S^n_{t_k^n}). \] (65)

Assume that $\Delta_n = O\left(\frac{1}{n}\right)$. Then there exists a constant $C > 0$ such that for all $n \in \mathbb{N}^*$,
\[ \sup_{t \in [0, T]} \mathbb{E}[|S_t - S^n_t|^2] \leq C \Delta_n. \]

**Proof.** Let $n \in \mathbb{N}^*$, $\Delta S^n := S - S^n$ and $t \in [t_{i-1}^n, t_i^n)$ for $i \in \llbracket 1, n \rrbracket$. We have for all $t \in [t_{i-1}^n, t_i^n)$,
\[ dS_t = \tilde{\sigma}(t, S_t) \, dW_t + \left( \tilde{\nu}(t, S_t) + \alpha_t (\tilde{\sigma} \partial_x \tilde{\lambda})(t, S_t) \right) \, dt + \tilde{\lambda}(t, S_t) \, d\tilde{\delta}_t, \]
\[ dS_i^n = \tilde{\sigma}(t, S_i^n) \, dW_t + \tilde{\nu}(t, S_i^n) \, dt, \]
which gives
\[ d\Delta S^n_t = dS_t - dS_t^n \]
\[ = (\tilde{\sigma}(t, S_t) - \tilde{\sigma}(t, S_i^n) + \alpha_t \tilde{\lambda}(t, S_t)) \, dW_t \]
\[ + (\tilde{\nu}(t, S_t) - \tilde{\nu}(t, S_i^n) + \alpha_t (\tilde{\sigma} \partial_x \tilde{\lambda})(t, S_t) + \beta_t \tilde{\lambda}(t, S_t)) \, dt. \]
Hence by Ito’s lemma,
\[ d|\Delta S^n_t|^2 = 2\Delta S^n_t d\Delta S^n_t + d(\Delta S^n, \Delta S^n)_t. \]

Therefore for all \( t \in [t^n_{i-1}, t^n_i) \),
\[
E[|\Delta S^n_t|^2] = E[|\Delta S^n_{t^n_{i-1}}|^2]
\]
\[
+ 2E \left[ \int_{t^n_{i-1}}^t \Delta S^n_t (\tilde{\nu}(s, S_s) - \nu(s, S^n_s) + \alpha_s (\tilde{\sigma} \partial_x \tilde{\lambda})(s, S_s) + \beta_s \tilde{\lambda}(s, S_s)) \, ds \right]
\]
\[
+ E \left[ \int_{t^n_{i-1}}^t (\tilde{\sigma}(s, S_s) - \sigma(s, S^n_s) + \alpha_s \tilde{\lambda}(s, S_s))^2 \, ds \right]
\]
\[
\leq E[|\Delta S^n_{t^n_{i-1}}|^2]
\]
\[
+ 2E \left[ \int_{t^n_{i-1}}^t |\Delta S^n_s||\nu(s, S_s) - \nu(s, S^n_s)| \, ds \right]
\]
\[
+ E \left[ \int_{t^n_{i-1}}^t (|\Delta S^n_s|^2 + |\alpha_s (\tilde{\sigma} \partial_x \tilde{\lambda})(s, S_s) + \beta_s \tilde{\lambda}(s, S_s)|^2)^2 \, ds \right]
\]
\[
+ 2E \int_{t^n_{i-1}}^t (|\tilde{\sigma}(s, S_s) - \sigma(s, S^n_s)|^2 + |\alpha_s \tilde{\lambda}(s, S_s)|^2) \, ds ,
\]

hence there exists a constant \( C_1 > 0 \) such that for all \( t \in [t^n_{i-1}, t^n_i) \),
\[
E[|\Delta S^n_t|^2] \leq E[|\Delta S^n_{t^n_{i-1}}|^2] + C_1 \Delta_n + C_1 \int_{t^n_{i-1}}^t E[|\Delta S^n_s|^2] \, ds. \tag{66}
\]

Applying Gronwall’s lemma we obtain for all \( t \in [t^n_{i-1}, t^n_i) \),
\[
E[|\Delta S^n_t|^2] \leq \left( E[|\Delta S^n_{t^n_{i-1}}|^2] + C_1 \Delta_n \right) \exp(C_1 (t - t^n_{i-1}))
\]
\[
\leq \left( E[|\Delta S^n_{t^n_{i-1}}|^2] + C_1 \Delta_n \right) \exp(C_1 \Delta_n). \tag{67}
\]

Plugging (67) in (66) leads to, for all \( t \in [t^n_{i-1}, t^n_i) \),
\[
E[|\Delta S^n_t|^2] \leq E[|\Delta S^n_{t^n_{i-1}}|^2] + C_1 \Delta_n + C_1 \Delta_n \left( E[|\Delta S^n_{t^n_{i-1}}|^2] + C_1 \Delta_n \right) \exp(C_1 \Delta_n)
\]
\[
\leq E[|\Delta S^n_{t^n_{i-1}}|^2] \left( 1 + C_1 \Delta_n \exp(C_1 \Delta_n) \right) + C_1 \Delta_n + C_1 \Delta_n \exp(C_1 \Delta_n).
\]

37
This implies that there exists a constant $C_2 > 0$ such that for all $t \in [t^i_n, t^o_n)\),

$$
\mathbb{E}[|\Delta S^i_n|^2] \leq \mathbb{E}[|\Delta S^o_{t^i_n}|^2](1 + C_2 \Delta n) + C_2 \Delta n.
$$

(68)

We have

$$
d((\delta t - \delta t^i_{n-1})\hat{\lambda}(t, S^i_n)) = (\delta t - \delta t^i_{n-1})d(\hat{\lambda}(t, S^i_n)) + \hat{\lambda}(t, S^i_n)d(\delta t - \delta t^i_{n-1}) + d(\delta - \delta t^i_{n-1}, \hat{\lambda}(., S^i_n))_t
$$

and

$$
d\hat{\lambda}(t, S^i_n) = (\tilde{\sigma}\partial_x\hat{\lambda})(t, S^i_n) dW_t + \left(\partial_t\hat{\lambda} + \tilde{\nu}\partial_x\hat{\lambda} + \frac{1}{2}\tilde{\sigma}^2\partial_{xx}\hat{\lambda}\right)(t, S^i_n) dt.
$$

This gives that

$$
d((\delta t - \delta t^i_{n-1})\hat{\lambda}(t, S^i_n)) = ((\delta t - \delta t^i_{n-1}) (\tilde{\sigma}\partial_x\hat{\lambda})(t, S^i_n) + \alpha_t\hat{\lambda}(t, S^i_n)) dW_t
$$

$$
+ (\delta t - \delta t^i_{n-1}) \left(\partial_t\hat{\lambda} + \tilde{\nu}\partial_x\hat{\lambda} + \frac{1}{2}\tilde{\sigma}^2\partial_{xx}\hat{\lambda}\right)(t, S^i_n) dt
$$

$$
+ (\beta_t\hat{\lambda}(t, S^i_n) + \alpha_t(\tilde{\sigma}\partial_x\hat{\lambda})(t, S^i_n)) dt,
$$

which implies that for all $t \in [t^i_{n-1}, t^i_n)$,

$$
(\delta t - \delta t^i_{n-1})\hat{\lambda}(t, S^i_n) = \mathcal{R}^{i,n}_t,
$$

by setting for all $t \in [t^i_{n-1}, t^i_n]$,

$$
\mathcal{R}^{i,n}_t := \int_{t^i_{n-1}}^t ((\delta s - \delta t^i_{n-1}) (\tilde{\sigma}\partial_x\hat{\lambda})(s, S^i_s) + \alpha_s\hat{\lambda}(s, S^i_s)) dW_s
$$

$$
+ \int_{t^i_{n-1}}^t (\delta s - \delta t^i_{n-1}) \left(\partial_t\hat{\lambda} + \tilde{\nu}\partial_x\hat{\lambda} + \frac{1}{2}\tilde{\sigma}^2\partial_{xx}\hat{\lambda}\right)(s, S^i_s) ds
$$

$$
+ \int_{t^i_{n-1}}^t (\beta_s\hat{\lambda}(s, S^i_s) + \alpha_s(\tilde{\sigma}\partial_x\hat{\lambda})(s, S^i_s)) ds.
$$

We set for all $t \in [t^i_{n-1}, t^i_n)$,

$$\tilde{S}^i_t := S^i_t + (\delta t - \delta t^i_{n-1})\hat{\lambda}(t, S^i_n).$$

Hence

$$\lim_{t \to (t^i_{n-1})^-} \tilde{S}^i_t = S^i_{t^i_{n-1}} + (\delta t - \delta t^i_{n-1})\hat{\lambda}(t^i_{n-1}, S^i_{t^i_{n-1}}) = S^i_n.$$

Let us consider now for all $t \in [t^i_{n-1}, t^i_n)$, $\Delta \tilde{S}^i_t := S_t - \tilde{S}^i_t = \Delta S^i_t - \mathcal{R}^{i,n}_t$. We have

$$d\Delta \tilde{S}^i_t = d\Delta S^i_t - d\mathcal{R}^{i,n}_t
$$

$$= (\tilde{\sigma}(t, S_t) - \tilde{\sigma}(t, S^i_n) + \alpha_t\hat{\lambda}(t, S_t)) dW_t
$$

$$+ (\tilde{\nu}(t, S_t) - \tilde{\nu}(t, S^i_n) + \alpha_t(\tilde{\sigma}\partial_x\hat{\lambda})(t, S_t) + \beta_t\hat{\lambda}(t, S_t)) dt
$$

$$- ((\delta_t - \delta t^i_{n-1}) (\tilde{\sigma}\partial_x\hat{\lambda})(t, S^i_n) + \alpha_t\hat{\lambda}(t, S^i_n)) dW_t
$$

$$- (\delta_t - \delta t^i_{n-1}) \left(\partial_t\hat{\lambda} + \tilde{\nu}\partial_x\hat{\lambda} + \frac{1}{2}\tilde{\sigma}^2\partial_{xx}\hat{\lambda}\right)(t, S^i_n) dt
$$

$$- (\beta_t\hat{\lambda}(t, S^i_n) + \alpha_t(\tilde{\sigma}\partial_x\hat{\lambda})(t, S^i_n)) dt
$$

This gives by Ito’s lemma,

$$d|\Delta \tilde{S}^i_t|^2 = 2\Delta \tilde{S}^i_t d\Delta \tilde{S}^i_t + d(\Delta \tilde{S}^i_n, \Delta \tilde{S}^i_n)_t$$

38
which implies that for all \( t \in [t^n_{i-1}, t^n_i) \),

\[
E[|\Delta \tilde{S}^n_t|^2] = E[|\Delta S^n_{t^n_{i-1}}|^2] \\
+ 2E \left[ \int_{t^n_{i-1}}^t \Delta \tilde{S}^n_s (\tilde{\nu}(s, S_s) - \nu(s, S^n_s)) \, ds \right] \\
+ 2E \left[ \int_{t^n_{i-1}}^t \Delta \tilde{S}^n_s \alpha_s (\tilde{\sigma} \partial_x \tilde{\lambda})(s, S_s) - (\tilde{\sigma} \partial_x \tilde{\lambda})(s, S^n_s) \, ds \right] \\
+ 2E \left[ \int_{t^n_{i-1}}^t \Delta \tilde{S}^n_s \beta_s (\tilde{\lambda}(s, S_s) - \tilde{\lambda}(s, S^n_s)) \, ds \right] \\
- 2E \left[ \int_{t^n_{i-1}}^t \Delta \tilde{S}^n_s (\delta_s - \delta_{t^n_{i-1}}) \left( \partial_t \tilde{\lambda} + \tilde{\nu} \partial_x \tilde{\lambda} + \frac{1}{2} \tilde{\sigma}^2 \partial_{xx} \tilde{\lambda} \right) (s, S^n_s) \, ds \right] \\
+ E \left[ \int_{t^n_{i-1}}^t \left( \tilde{\sigma}(s, S_s) - \sigma(s, S^n_s) + \alpha_s (\tilde{\lambda}(s, S_s) - \tilde{\lambda}(s, S^n_s)) - (\delta_s - \delta_{t^n_{i-1}})(\tilde{\sigma} \partial_x \tilde{\lambda})(s, S^n_s) \right)^2 \, ds \right] 
\]

leading to for all \( t \in [t^n_{i-1}, t^n_i) \),

\[
E[|\Delta \tilde{S}^n_t|^2] \leq E[|\Delta S^n_{t^n_{i-1}}|^2] \\
\leq E \left[ \int_{t^n_{i-1}}^t |\Delta \tilde{S}^n_s||\tilde{\nu}(s, S_s) - \nu(s, S^n_s)| \, ds \right] \\
+ 2E \left[ \int_{t^n_{i-1}}^t |\Delta \tilde{S}^n_s||\alpha_s||\tilde{\sigma} \partial_x \tilde{\lambda})(s, S_s) - (\tilde{\sigma} \partial_x \tilde{\lambda})(s, S^n_s)| \, ds \right] \\
+ 2E \left[ \int_{t^n_{i-1}}^t |\Delta \tilde{S}^n_s||\beta_s||\tilde{\lambda}(s, S_s) - \tilde{\lambda}(s, S^n_s)| \, ds \right] \\
+ E \left[ \int_{t^n_{i-1}}^t \left( |\Delta \tilde{S}^n_s|^2 + |\delta_s - \delta_{t^n_{i-1}}|^2 \right) \left( \partial_t \tilde{\lambda} + \tilde{\nu} \partial_x \tilde{\lambda} + \frac{1}{2} \tilde{\sigma}^2 \partial_{xx} \tilde{\lambda} \right)^2 (s, S^n_s) \, ds \right] \\
+ 3E \left[ \int_{t^n_{i-1}}^t |\tilde{\sigma}(s, S_s) - \sigma(s, S^n_s)|^2 \, ds \right] \\
+ 3E \left[ \int_{t^n_{i-1}}^t |\alpha_s|^2 ||\tilde{\lambda}(s, S_s) - \tilde{\lambda}(s, S^n_s)|^2 \, ds \right] \\
+ 3E \left[ \int_{t^n_{i-1}}^t |\delta_s - \delta_{t^n_{i-1}}|^2 |(\tilde{\sigma} \partial_x \tilde{\lambda})(s, S^n_s)|^2 \, ds \right] 
\]

hence there exists a constant \( C_3 > 0 \) such that for all \( t \in [t^n_{i-1}, t^n_i) \),

\[
E[|\Delta \tilde{S}^n_t|^2] \leq E[|\Delta S^n_{t^n_{i-1}}|^2] + C_3 \int_{t^n_{i-1}}^t \left( E[\delta_s - \delta_{t^n_{i-1}}|^2] + E[|\Delta S^n_s|^2] + E[|\Delta \tilde{S}^n_s|^2] \right) \, ds. \tag{69} 
\]

Besides by Proposition \( \text{A.7.1} \) there exists a constant \( C_4 > 0 \) such that for all \( t \in [t^n_{i-1}, t^n_i) \),

\[
E[|\delta_t - \delta_{t^n_{i-1}}|^2] \leq C_4 \Delta_n, \tag{70} 
\]

39
therefore by plugging (68) and (70) in the inequality (69) we obtain that for all \( t \in [t^n_{i-1}, t^n_i] \),
\[
E[|\Delta \tilde{S}^n_t|^2] \leq E[|\Delta S^n_{t_{i-1}}|^2] + C_5 C_4 \Delta^2_n + C_3 \Delta_n \left( E[|\Delta S^n_{t_{i-1}}|^2](1 + C_2 \Delta_n) + C_2 \Delta_n \right) + C_3 \int_{t^n_{i-1}}^t E[|\Delta S^n_s|^2] \, ds
\]
\[
\leq E[|\Delta S^n_{t_{i-1}}|^2] \left( 1 + C_3 \Delta_n + C_2 C_3 \Delta^2_n \right) + \left( C_2 + C_4 \right) C_3 \Delta^2_n + C_3 \int_{t^n_{i-1}}^t E[|\Delta \tilde{S}^n_s|^2] \, ds.
\]
Hence there exists a constant \( C_5 > 0 \) such that for all \( t \in [t^n_{i-1}, t^n_i] \),
\[
E[|\Delta \tilde{S}^n_t|^2] \leq E[|\Delta S^n_{t_{i-1}}|^2](1 + C_5 \Delta_n) + C_5 \Delta^2_n + C_5 \int_{t^n_{i-1}}^t E[|\Delta \tilde{S}^n_s|^2] \, ds,
\]
which implies by Gronwall’s lemma that for all \( t \in [t^n_{i-1}, t^n_i] \),
\[
E[|\Delta \tilde{S}^n_t|^2] \leq \exp(C_5(t - t^n_{i-1})) \left( E[|\Delta S^n_{t_{i-1}}|^2](1 + C_5 \Delta_n) + C_5 \Delta^2_n \right)
\]
\[
\leq \exp(C_5 \Delta_n) \left( E[|\Delta S^n_{t_{i-1}}|^2](1 + C_5 \Delta_n) + C_5 \Delta^2_n \right).
\]
By plugging the inequality (72) in (71), we get
\[
E[|\Delta \tilde{S}^n_t|^2] \leq E[|\Delta S^n_{t_{i-1}}|^2](1 + C_5 \Delta_n) + C_5 \Delta^2_n + C_5 \Delta_n \exp(C_5 \Delta_n) \left( E[|\Delta S^n_{t_{i-1}}|^2](1 + C_5 \Delta_n) + C_5 \Delta^2_n \right)
\]
\[
\leq E[|\Delta S^n_{t_{i-1}}|^2] \left( 1 + C_5 \Delta_n + C_5 \Delta_n \exp(C_5 \Delta_n) + C_5 \Delta^2_n \exp(C_5 \Delta_n) \right)
\]
\[
+ \left( C_5 \Delta^2_n + C_5 \Delta^2_n \exp(C_5 \Delta_n) \right).
\]
Therefore there exists a constant \( C_6 > 0 \) such that for all \( t \in [t^n_{i-1}, t^n_i] \),
\[
E[|\Delta \tilde{S}^n_t|^2] \leq E[|\Delta S^n_{t_{i-1}}|^2](1 + C_6 \Delta_n) + C_6 \Delta^2_n.
\]
Let \((\tau^i_k)_{k \in \mathbb{N}}\) a non-decreasing sequence such that \( \lim_{k \to +\infty} \tau^i_k = t^n_i \), by Fatou’s lemma we have
\[
E \left[ \liminf_{k \to +\infty} |\Delta \tilde{S}^n_{\tau^i_k,n}|^2 \right] \leq \liminf_{k \to +\infty} E[|\Delta \tilde{S}^n_{\tau^i_k,n}|^2] \leq E[|\Delta S^n_{t^n_i}|^2](1 + C_6 \Delta_n) + C_6 \Delta^2_n,
\]
and
\[
E \left[ \liminf_{k \to +\infty} |\Delta \tilde{S}^n_{\tau^i_k,n}|^2 \right] = E \left[ \lim_{k \to +\infty} |\Delta \tilde{S}^n_{\tau^i_k,n}|^2 \right] = E[|\Delta S^n_{t^n_i}|^2]
\]
since \( \lim_{t \to (t^n_i)^-} \Delta \tilde{S}^n_t = \Delta S^n_{t^n_i} \). Therefore we have for all \( n \in \mathbb{N}^*, i \in [1, n] \),
\[
E[|\Delta S^n_{t^n_i}|^2] \leq E[|\Delta S^n_{t_{i-1}}|^2](1 + C_6 \Delta_n) + C_6 \Delta^2_n
\]
\[
\leq E[|\Delta S^n_{t_{i-1}}|^2](1 + C_6 \Delta_n)^2 + C_6 \Delta^2_n(1 + C_6 \Delta_n) + C_6 \Delta^2_n
\]
\[
\ldots
\]
\[
\leq E[|\Delta S^n_{t_0}|^2](1 + C_6 \Delta_n) + C_6 \Delta^2_n \sum_{k=0}^{i-1} (1 + C_6 \Delta_n)^k.
\]
Considering the fact that $\Delta S_{t_0}^n = 0$, we have for all $n \in \mathbb{N}^*, i \in [1, n]$

$$
\mathbb{E}[|\Delta S_i^n|^2] \leq C_6 \Delta_n^2 \frac{(1 + C_6 \Delta_n)^i - 1}{C_6 \Delta_n} \leq \Delta_n (1 + C_6 \Delta_n)^n \leq \Delta_n \exp \left( n \ln(1 + C_6 \Delta_n) \right) \leq \Delta_n \exp(C_6 n \Delta_n).
$$

Hence there exists a constant $C_7 > 0$ such that for all $n \in \mathbb{N}^*, i \in [0, n]$

$$
\mathbb{E}[|\Delta S_i^n|^2] \leq C_7 \Delta_n
$$

and for all $n \in \mathbb{N}^*, i \in [0, n], t \in [t^n_{i-1}, t^n_i)$,

$$
\mathbb{E}[|\Delta S_t^n|^2] \leq \mathbb{E}[|\Delta S_{t^n_{i-1}}^n|^2](1 + C_2 \Delta_n) + C_2 \Delta_n^2 \leq C_7 \Delta_n(1 + C_2 \Delta_n) + C_2 \Delta_n^2 = O(\Delta_n)
$$

which implies that there exists a constant $C_8 > 0$ such that for all $n \in \mathbb{N}^*, i \in [1, n]$

$$
\sup_{t \in [t^n_{i-1}, t^n_i]} \mathbb{E}[|\Delta S_t^n|^2] \leq C_8 \Delta_n.
$$

This gives that for all $n \in \mathbb{N}^*$,

$$
\sup_{t \in [0, T]} \mathbb{E}[|\Delta S_t^n|^2] = \max_{1 \leq i \leq n} \sup_{t \in [t^n_{i-1}, t^n_i]} \mathbb{E}[|\Delta S_t^n|^2] \leq C_8 \Delta_n.
$$

Proposition A.7.3. Suppose the assumptions of Theorem 8 hold. Let $(V^n)_{n \in \mathbb{N}}$ a sequence of processes on $[0, T]$ such that for all $t \in [0, T]$,

$$
V^n_t := V_0 + \sum_{k=1}^n 1_{\{t^n_{k-1} \leq t \leq T\}} \delta t^n_{k-1} (\hat{S}_{k,T}^n - \hat{S}_{k-1}^n) + 1_{\{t \leq t^n_{i-1}\}} \left[ \frac{1}{2} (\delta t^n_k - \delta t^n_{k-1})^2 \tilde{\lambda}(t^n_k, S^n_{k-1}) + \delta t^n_{k-1} (\delta t^n_k - \delta t^n_{k-1}) \lambda(t^n_k, S^n_{k-1}) \right]. \quad (73)
$$

Assume that $\Delta_n = O \left( \frac{1}{n} \right)$. Then there exists a constant $C > 0$ such that for all $n \in \mathbb{N}^*$,

$$
\sup_{t \in [0, T]} \mathbb{E}[|V_t - V^n_t|^2] \leq C \Delta_n.
$$

Proof. Let $n \in \mathbb{N}^*, \Delta V^n := V - V^n$ and $t \in [t^n_{i-1}, t^n_i)$ for $i \in [1, n]$. We have for all $t \in [t^n_{i-1}, t^n_i)$,

$$
dV_t = \delta_t dS_t + \frac{1}{2} \tilde{\lambda}(t, S_t) \alpha_t^2 dt
$$

$$
dV^n_t = \delta_t dS_t^n,
$$
which leads to
\[
\begin{align*}
    d\Delta V^n_t &= dV^n_t - dV^n_{t-1} \\
    &= \left( \delta_t \tilde{\sigma}(t, S_t) - \delta_{t-1} \tilde{\sigma}(t, S^n_{t-1}) + \delta_t \alpha(t, S_t) \right) dW_t \\
    &\quad + \left( \delta_t \tilde{\nu}(t, S_t) - \delta_{t-1} \tilde{\nu}(t, S^n_{t-1}) + \frac{1}{2} \delta_t^2 \lambda(t, S_t) + \delta_t \alpha(t, \tilde{\sigma}(t, S_t)) \right) dt.
\end{align*}
\]

By Ito’s lemma we have
\[
d\Delta V^n_t = 2\Delta V^n_{t-1} d\Delta V^n_t + d(\Delta V^n, \Delta V^n)_t,
\]
which gives for all \( t \in [t^n_{i-1}, t^n_i) \),
\[
E[|\Delta V^n_t|^2] = E[|\Delta V^n_{t-1}|^2] \\
+ 2E \left[ \int^{t^n_i}_{t^n_{i-1}} \Delta V^n_s \left( \delta_s \tilde{\sigma}(s, S_s) - \delta_{s-1} \tilde{\sigma}(s, S^n_{s-1}) \right) ds \right] \\
+ 2E \left[ \int^{t^n_i}_{t^n_{i-1}} \Delta V^n_s \left( \frac{1}{2} \alpha^2_s \tilde{\lambda}(s, S_s) + \delta_s \beta_s \tilde{\lambda}(s, S_s) + \delta_s \alpha_s (\tilde{\sigma} \tilde{\lambda})(s, S_s) \right) ds \right] \\
+ E \left[ \int^{t^n_i}_{t^n_{i-1}} \left( \delta_s \tilde{\sigma}(s, S_s) - \delta_{s-1} \tilde{\sigma}(s, S^n_{s-1}) \right)^2 ds \right] \\
\leq E[|\Delta V^n_{t-1}|^2] \\
+ E \left[ \int^{t^n_i}_{t^n_{i-1}} \left( |\Delta V^n_s|^2 + |\delta_s \tilde{\sigma}(s, S_s) - \delta_{s-1} \tilde{\sigma}(s, S^n_{s-1})|^2 \right) ds \right] \\
+ E \left[ \int^{t^n_i}_{t^n_{i-1}} \left( |\Delta V^n_s|^2 + \frac{1}{2} \alpha^2_s \tilde{\lambda}(s, S_s) + \delta_s \beta_s \tilde{\lambda}(s, S_s) + \delta_s \alpha_s (\tilde{\sigma} \tilde{\lambda})(s, S_s) \right)^2 ds \right] \\
+ 2E \left[ \int^{t^n_i}_{t^n_{i-1}} \left( |\delta_s \tilde{\sigma}(s, S_s) - \delta_{s-1} \tilde{\sigma}(s, S^n_{s-1})|^2 + |\delta_s \alpha_s f(s, S_s)|^2 \right) ds \right].
\]

Besides for all function \( h : (t, x) \in \mathbb{R}^2 \mapsto \mathbb{R} \) bounded and Lipschitz in the space variable we have for all \( t \in [t^n_{i-1}, t^n_i) \),
\[
E[|\delta_s h(s, S_s) - \delta_{s-1} h(s, S^n_{s-1})|^2] \leq 2E[|h(s, S^n_s)|^2 |\delta_s - \delta_{s-1} h(s, S^n_s)|^2] + 2E[|\delta_{s-1} h(s, S^n_s)|^2 |h(s, S_s) - h(s, S^n_s)|^2] \\
\leq 2E[|h(s, S^n_s)|^2 |\delta_s - \delta_{s-1} h(s, S^n_s)|^2] + 2\sqrt{E[|\delta_{s-1} h(s, S^n_s)|^2]} \sqrt{E[|h(s, S_s) - h(s, S^n_s)|^2]}
\]
which implies that there exists a constant \( C_h > 0 \) such that for all \( t \in [t^n_{i-1}, t^n_i) \),
\[
E[|\delta_s h(s, S_s) - \delta_{s-1} h(s, S^n_{s-1})|^2] \leq C_h \left( E[|S_s - S^n_s|^2] + E[|\delta_s - \delta_{s-1} h(s, S^n_s)|^2] \right). \tag{74}
\]

Hence by (74) there exists a constant \( C_1 > 0 \) such that for all \( t \in [t^n_{i-1}, t^n_i) \),
\[
E[|\Delta V^n_t|^2] \leq E[|\Delta V^n_{t-1}|^2] \\
+ C_1 \int^{t^n_i}_{t^n_{i-1}} \left( 1 + E[|\Delta V^n_s|^2] + E[|S_s - S^n_s|^2] + E[|\delta_s - \delta_{s-1} h(s, S^n_s)|^2] \right) ds. \tag{75}
\]
By plugging the Propositions A.7.1 and A.7.2 in the inequality (75), we obtain that there exists a constant $C_2 > 0$ such that for all $t \in [t_{n-1}^n, t_n^n)$,

$$\mathbb{E}[|\Delta V_{t_i}^n|^2] \leq \mathbb{E}[|\Delta V_{t_{n-1}}^n|^2] + C_2 \Delta n + C_2 \int_{t_{n-1}^n}^t \mathbb{E}[|\Delta V_{s_i}^n|^2] \, ds.$$  \hfill (76)

By applying Gronwall’s lemma, similarly as the inequality (66) leads to the inequality (68), the inequality (76) implies also that there exists a constant $C_3 > 0$ such that for all $t \in [t_{n-1}^n, t_n^n)$,

$$\mathbb{E}[|\Delta V_{t_i}^n|^2] \leq \mathbb{E}[|\Delta V_{t_{n-1}}^n|^2](1 + C_3 \Delta n) + C_3 \Delta n.$$  \hfill (77)

We have for all $t \in [t_{n-1}^n, t_n^n)$,

$$d(|\delta_t - \delta_{t_{n-1}}|^2 \tilde{\lambda}(t, S_t^n)) = |\delta_t - \delta_{t_{n-1}}|^2 d(\tilde{\lambda}(t, S_t^n)) + \tilde{\lambda}(t, S_t^n) d(|\delta_t - \delta_{t_{n-1}}|^2) + d(|\delta_t - \delta_{t_{n-1}}|^2 \tilde{\lambda}(t, S_t^n))$$
with

$$d\tilde{\lambda}(t, S_t^n) = (\tilde{\sigma} \partial_x \tilde{\lambda})(t, S_t^n) dW_t + \left( \partial_t \tilde{\lambda} + \tilde{\nu} \partial_x \tilde{\lambda} + \frac{1}{2} \tilde{\sigma}^2 \partial_{xx} \tilde{\lambda} \right) (t, S_t^n) dt,$$

and

$$d|\delta_t - \delta_{t_{n-1}}|^2 = 2(\delta_t - \delta_{t_{n-1}}) \alpha_t dW_t + (2(\delta_t - \delta_{t_{n-1}}) \beta_t + \alpha_t^2) dt.$$  

Therefore for all $t \in [t_{n-1}^n, t_n^n)$,

$$d(|\delta_t - \delta_{t_{n-1}}|^2 \tilde{\lambda}(t, S_t^n)) = \left[ |\delta_t - \delta_{t_{n-1}}|^2 (\tilde{\sigma} \partial_x \tilde{\lambda})(t, S_t^n) dW_t + 2(\delta_t - \delta_{t_{n-1}}) \alpha_t \tilde{\lambda}(t, S_t^n) dW_t ight.$$
\begin{align*}
+ |\delta_t - \delta_{t_{n-1}}|^2 \left( \partial_t \tilde{\lambda} + \tilde{\nu} \partial_x \tilde{\lambda} + \frac{1}{2} \tilde{\sigma}^2 \partial_{xx} \tilde{\lambda} \right) (t, S_t^n) dt \\
+ (2(\delta_t - \delta_{t_{n-1}}) \beta_t + \alpha_t^2) \tilde{\lambda}(t, S_t^n) dt \\
+ 2(\delta_t - \delta_{t_{n-1}}) \alpha_t (\tilde{\sigma} \partial_x \tilde{\lambda})(t, S_t^n) dt,
\end{align*}

which implies that for all $t \in [t_{n-1}^n, t_n^n)$,

$$|\delta_t - \delta_{t_{n-1}}|^2 \tilde{\lambda}(t, S_t^n) = S_{t_i}^{t_{n-1}},$$

by setting for all $t \in [t_{n-1}^n, t_n^n)$,

$$S_{t_i}^{t_{n-1}} := \int_{t_{n-1}^n}^t |\delta_s - \delta_{t_{n-1}}|^2 (\tilde{\sigma} \partial_x \tilde{\lambda})(s, S_s^n) \, dW_s + \int_{t_{n-1}^n}^t 2(\delta_s - \delta_{t_{n-1}}) \alpha_s \tilde{\lambda}(s, S_s^n) \, dW_s$$
\begin{align*}
+ \int_{t_{n-1}^n}^t |\delta_s - \delta_{t_{n-1}}|^2 \left( \partial_t \tilde{\lambda} + \tilde{\nu} \partial_x \tilde{\lambda} + \frac{1}{2} \tilde{\sigma}^2 \partial_{xx} \tilde{\lambda} \right) (s, S_s^n) \, ds \\
+ \int_{t_{n-1}^n}^t (2(\delta_s - \delta_{t_{n-1}}) \beta_s + \alpha_s^2) \tilde{\lambda}(s, S_s^n) \, ds \\
+ \int_{t_{n-1}^n}^t 2(\delta_s - \delta_{t_{n-1}}) \alpha_s (\tilde{\sigma} \partial_x \tilde{\lambda})(s, S_s^n) \, ds.
\end{align*}
We set for all \( t \in [t^n_{i-1}, t^n_i) \), \( \tilde{V}^n_t := V^n_t + \delta^n_{i-1} (\delta_t - \delta^n_{i-1}) \tilde{\lambda}(t, S^n_t) + \frac{1}{2} (\delta_t - \delta^n_{i-1})^2 \tilde{\lambda}(t, S^n_t) \). Hence

\[
\lim_{t \to (t^n_i)} \tilde{V}^n_t = V^n_{t^n_i} + \delta^n_{i-1} (\delta_t - \delta^n_{i-1}) \tilde{\lambda}(t^n_i, S^n_{t^n_i}) + \frac{1}{2} (\delta_t - \delta^n_{i-1})^2 \tilde{\lambda}(t^n_i, S^n_{t^n_i}) = V^n_{t^n_i}.
\]

Let us consider now for all \( t \in [t^n_{i-1}, t^n_i) \), \( \Delta V^n_t := V_t - \tilde{V}^n_t = \Delta V^n_t - \delta^n_{i-1} \mathcal{R}^{i,n}_t - \frac{1}{2} S^n_t \), where \( \mathcal{R}^{i,n} \) is defined, as previously, such that for all \( t \in [t^n_{i-1}, t^n_i) \),

\[
\mathcal{R}^{i,n}_t := \int_{t^n_{i-1}}^t \left( (\delta_s - \delta^n_{i-1}) (\tilde{\sigma} \partial_x \tilde{\lambda})(s, S^n_s) + \alpha_s \tilde{\lambda}(s, S^n_s) \right) \, dW_s + \left( \delta_s - \delta^n_{i-1} \right) \left( \partial_t \tilde{\lambda} + \tilde{\nu} \partial_x \tilde{\lambda} + \frac{1}{2} \tilde{\sigma}^2 \partial_{xx} \tilde{\lambda} \right) (s, S^n_s) \, ds + \left( \delta_s - \delta^n_{i-1} \right) (\beta_s \tilde{\lambda}(s, S^n_s) + \alpha_s (\tilde{\sigma} \partial_x \tilde{\lambda})(s, S^n_s)) \, ds.
\]

We have by Ito's lemma

\[
d|\Delta \tilde{V}^n_t|^2 = 2 \Delta \tilde{V}^n_t \, d\Delta \tilde{V}^n_t + d(\Delta \tilde{V}^n_t, \Delta \tilde{V}^n_t)_t,
\]

hence for all \( t \in [t^n_{i-1}, t^n_i) \),

\[
d|\Delta \tilde{V}^n_t|^2 = 2 \Delta \tilde{V}^n_t \left( \delta_t \tilde{\sigma}(t, S^n_t) - \delta^n_{i-1} \tilde{\sigma}(t, S^n_t) + \delta_t \alpha_t \tilde{\lambda}(t, S^n_t) \right) \, dW_t + 2 \Delta \tilde{V}^n_t \left( \delta_t \tilde{\nu}(t, S^n_t) - \delta^n_{i-1} \tilde{\nu}(t, S^n_t) + \frac{1}{2} \alpha^2 \tilde{\lambda}(t, S^n_t) + \alpha_t \tilde{\lambda}(t, S^n_t) \right) \, dt
\]

\[- \frac{1}{2} \Delta \tilde{V}^n_t \left( \delta_t - \delta^n_{i-1} \right) \left( \partial_t \tilde{\lambda} + \tilde{\nu} \partial_x \tilde{\lambda} + \frac{1}{2} \tilde{\sigma}^2 \partial_{xx} \tilde{\lambda} \right) (t, S^n_t) \, dt
\]

\[- 2 \Delta \tilde{V}^n_t \delta^n_{i-1} \left( \beta_t \tilde{\lambda}(t, S^n_t) + \alpha_t (\tilde{\sigma} \partial_x \tilde{\lambda})(t, S^n_t) \right) \, dt
\]

\[- 2 \Delta \tilde{V}^n_t \left( \delta_t - \delta^n_{i-1} \right) \left( \beta_t \tilde{\lambda}(t, S^n_t) + \alpha_t (\tilde{\sigma} \partial_x \tilde{\lambda})(t, S^n_t) \right) \, dt
\]

\[- 2 \Delta \tilde{V}^n_t \left( \delta_t - \delta^n_{i-1} \right) \left( \beta_t \tilde{\lambda}(t, S^n_t) + \alpha_t (\tilde{\sigma} \partial_x \tilde{\lambda})(t, S^n_t) \right) \, dt
\]

We have

\[
\frac{1}{2} | \delta_t - \delta^n_{i-1} |^2 \partial_t \tilde{\lambda} + \frac{1}{2} \tilde{\sigma}^2 \partial_{xx} \tilde{\lambda} \, dt
\]

\[
\frac{1}{2} | \delta_t - \delta^n_{i-1} |^2 \partial_t \tilde{\lambda} + \frac{1}{2} \tilde{\sigma}^2 \partial_{xx} \tilde{\lambda} \, dt
\]

\[
\frac{1}{2} | \delta_t - \delta^n_{i-1} |^2 \partial_t \tilde{\lambda} + \frac{1}{2} \tilde{\sigma}^2 \partial_{xx} \tilde{\lambda} \, dt
\]

\[
\frac{1}{2} | \delta_t - \delta^n_{i-1} |^2 \partial_t \tilde{\lambda} + \frac{1}{2} \tilde{\sigma}^2 \partial_{xx} \tilde{\lambda} \, dt
\]

\[
\frac{1}{2} | \delta_t - \delta^n_{i-1} |^2 \partial_t \tilde{\lambda} + \frac{1}{2} \tilde{\sigma}^2 \partial_{xx} \tilde{\lambda} \, dt
\]

\[
\frac{1}{2} | \delta_t - \delta^n_{i-1} |^2 \partial_t \tilde{\lambda} + \frac{1}{2} \tilde{\sigma}^2 \partial_{xx} \tilde{\lambda} \, dt
\]
Therefore, for all $t \in [t_{n-1}^i, t_n^i)$,

$$E[|\Delta \tilde{V}_s^m|^2] = E[|\Delta V_{n-1}^m|^2]$$

$$+ 2E \left[ \int_{t_{n-1}^i}^t \Delta \tilde{V}_s^m (\delta_s \tilde{v}(s, S_s) - \delta_{n-1}^i \tilde{v}(s, S_{n-1}^m)) \, ds \right]$$

$$+ 2E \left[ \int_{t_{n-1}^i}^t \Delta \tilde{V}_s^m \frac{1}{2} \alpha_s^2 (\tilde{\lambda}(s, S_s) - \tilde{\lambda}(s, S_{n-1}^m)) \, ds \right]$$

$$+ 2E \left[ \int_{t_{n-1}^i}^t \Delta \tilde{V}_s^m \beta_s (\delta_s \tilde{\lambda}(s, S_s) - \delta_{n-1}^i \tilde{\lambda}(s, S_{n-1}^m)) \, ds \right]$$

$$+ 2E \left[ \int_{t_{n-1}^i}^t \Delta \tilde{V}_s^m \alpha_s \delta_s (\delta_s \tilde{\sigma}(s, S_s) - \delta_{n-1}^i \tilde{\sigma}(s, S_{n-1}^m)) \, ds \right]$$

$$+ 2E \left[ \int_{t_{n-1}^i}^t \Delta \tilde{V}_s^m \alpha_s (\delta_s (\tilde{\sigma} \partial_x \tilde{\lambda})(s, S_s) - \delta_{n-1}^i (\tilde{\sigma} \partial_x \tilde{\lambda})(s, S_{n-1}^m)) \, ds \right]$$

$$+ 2E \left[ \int_{t_{n-1}^i}^t \Delta \tilde{V}_s^m (\tilde{\lambda} - \tilde{\lambda}(s, S_s) + \frac{1}{2} \sigma^2 \partial_{xx} \tilde{\lambda})(s, S_{n-1}^m)) \, ds \right]$$

$$+ 2E \left[ \int_{t_{n-1}^i}^t \Delta \tilde{V}_s^m (\tilde{\lambda} - \tilde{\lambda}(s, S_s) + \frac{1}{2} \sigma^2 \partial_{xx} \tilde{\lambda})(s, S_{n-1}^m)) \, ds \right]$$

$$+ 2E \left[ \int_{t_{n-1}^i}^t \Delta \tilde{V}_s^m (\tilde{\lambda} - \tilde{\lambda}(s, S_s) + \frac{1}{2} \sigma^2 \partial_{xx} \tilde{\lambda})(s, S_{n-1}^m)) \, ds \right]$$

$$+ \frac{1}{2} (\delta_t - \delta_{n-1}^i)(\tilde{\sigma} \partial_x \tilde{\lambda})(t, S_{n-1}^m) + \alpha_t \tilde{\lambda}(t, S_{n-1}^m)).$$

with $\gamma_{i,n}^m$ defined such as for all $t \in [t_{n-1}^i, t_n^i)$,

$$\gamma_{i,n}^m := \delta_t \tilde{\sigma}(t, S_t) - \delta_{n-1}^i \tilde{\sigma}(t, S_{n-1}^m)$$

$$+ \alpha_t (\delta_t \tilde{\lambda}(t, S_t) - \delta_{n-1}^i \tilde{\lambda}(t, S_{n-1}^m))$$

$$- (\delta_t - \delta_{n-1}^i)(\delta_{n-1}^i \tilde{\sigma} \partial_x \tilde{\lambda})(t, S_{n-1}^m) + \frac{1}{2} (\delta_t - \delta_{n-1}^i)(\tilde{\sigma} \partial_x \tilde{\lambda})(t, S_{n-1}^m) + \alpha_t \tilde{\lambda}(t, S_{n-1}^m)).$$
Hence, this gives that for all $t \in [t^n_{i-1}, t^n_i]$,

$$ E[|\Delta \tilde{V}^n_t|^2] \leq E[|\Delta V^n_{t^n_{i-1}}|^2] $$

$$ + E \left[ \int_{t^n_{i-1}}^t \left( |\Delta \tilde{V}^n_s|^2 + |\delta_s \tilde{\nu}(s, S_s) - \delta_{t^n_{i-1}} \tilde{\nu}(s, S^n_s)|^2 \right) ds \right] $$

$$ + E \left[ \int_{t^n_{i-1}}^t \left( |\Delta \tilde{V}^n_s|^2 + \left| \frac{1}{2} \sigma_s^2 \right| \left| \tilde{\lambda}(s, S_s) - \tilde{\lambda}(s, S^n_s) \right|^2 \right) ds \right] $$

$$ + E \left[ \int_{t^n_{i-1}}^t \left( |\Delta \tilde{V}^n_s|^2 + |\beta_s^2| \tilde{\lambda}(s, S_s) - \delta_{t^n_{i-1}} \tilde{\lambda}(s, S^n_s) \right)^2 \right] $$

$$ + E \left[ \int_{t^n_{i-1}}^t \left( |\Delta \tilde{V}^n_s|^2 + |\alpha_s^2| \delta_s \tilde{\lambda}(s, S_s) - \delta_{t^n_{i-1}} (\tilde{\sigma} \tilde{\partial}_x \tilde{\lambda}) (s, S^n_s) \right)^2 \right] $$

$$ + E \left[ \int_{t^n_{i-1}}^t \left( |\Delta \tilde{V}^n_s|^2 + \left| \frac{1}{2} \tilde{\partial}_x \tilde{\lambda} + \tilde{\nu} \partial_x \tilde{\lambda} + \frac{1}{2} \tilde{\sigma}^2 \partial_x \tilde{\lambda} \right)^2 \right) \delta_{t^n_{i-1}} (\delta_s - \delta_{t^n_{i-1}})^2 \right] $$

$$ + E \left[ \int_{t^n_{i-1}}^t \left( |\Delta \tilde{V}^n_s|^2 + \left| \beta_s (s, S^n_s) + \alpha_s (\tilde{\sigma} \tilde{\partial}_x \tilde{\lambda})(s, S^n_s) \right|^2 \right) \delta_{s} - \delta_{t^n_{i-1}}^2 \right] $$

$$ + 5E \left[ \int_{t^n_{i-1}}^t \left| \delta_s \tilde{\sigma}(s, S_s) - \delta_{t^n_{i-1}} \tilde{\sigma}(s, S^n_s) \right|^2 \right] $$

$$ + 5E \left[ \int_{t^n_{i-1}}^t \left| \alpha_s \tilde{\lambda}(s, S_s) - \delta_{t^n_{i-1}} \tilde{\lambda}(s, S^n_s) \right|^2 \right] $$

$$ + 5E \left[ \int_{t^n_{i-1}}^t \left| \sigma \tilde{\partial}_x \tilde{\lambda}(s, S^n_s) \right|^2 \delta_{t^n_{i-1}} (\delta_s - \delta_{t^n_{i-1}})^2 \right] $$

$$ + 5E \left[ \int_{t^n_{i-1}}^t \left| \frac{1}{2} \tilde{\sigma} \tilde{\partial}_x \tilde{\lambda}(s, S^n_s) \right|^2 \delta_{s} - \delta_{t^n_{i-1}}^4 \right] $$

$$ + 5E \left[ \int_{t^n_{i-1}}^t \left| \alpha_s \tilde{\lambda}(s, S^n_s) \right|^2 \delta_s - \delta_{t^n_{i-1}}^2 \right] .$$
which implies that there exists a constant $C_4 > 0$ such that for all $t \in [t_{i-1}^n, t_i^n)$,
\[
\mathbb{E}[|\Delta \tilde{V}_n|^2] \leq \mathbb{E}[|\Delta V_{t_{i-1}^n}^n|^2] + C_4 \int_{t_{i-1}^n}^t (\mathbb{E}[|\Delta \tilde{V}_n|^2] + \mathbb{E}[|S_s - S_s^n|^2] + \mathbb{E}[|\delta_s - \delta_s^n|^2]) \, ds
\]
\[
+ C_4 \int_{t_{i-1}^n}^t (\mathbb{E}[|\delta_{t_{i-1}^n} - \delta_{t_{i-1}^n}^n|^2] + \mathbb{E}[|\delta_s - \delta_{t_{i-1}^n}^n|^4]) \, ds
\]
\[
\leq \mathbb{E}[|\Delta V_{t_{i-1}^n}^n|^2]
\]
\[
+ C_4 \int_{t_{i-1}^n}^t (\mathbb{E}[|\Delta \tilde{V}_n|^2] + \mathbb{E}[|S_s - S_s^n|^2] + \mathbb{E}[|\delta_s - \delta_s^n|^2]) \, ds
\]
\[
+ C_4 \int_{t_{i-1}^n}^t \left( \sqrt{\mathbb{E}[|\delta_{t_{i-1}^n}^n|^4]} + \sqrt{\mathbb{E}[|\delta_s - \delta_{t_{i-1}^n}^n|^4]} + \sqrt{\mathbb{E}[|\delta_s - \delta_t^n|^4]} \right) \, ds. \quad (78)
\]

Besides by the generalized Minkowski inequality and the Burkholder-Davis-Gundy inequality (see for instance Section 7.8.1 in [Pagès, 2018]) we have that there exists $K > 0$ such that for all $t \in [t_{i-1}^n, t_i^n)$,
\[
\|\delta_t - \delta_t^n\|_4 \leq K \sqrt{\Delta_n},
\]

hence
\[
\sqrt{\mathbb{E}[|\delta_s - \delta_{t_{i-1}^n}^n|^4]} = \|\delta_t - \delta_{t_{i-1}^n}^n\|^2_4 \leq K^2 \Delta_n. \quad (79)
\]

By plugging (74), (79), Propositions A.7.1 and A.7.2 in the inequality (78), we obtain that there exists a constant $C_5 > 0$ such that for all $t \in [t_{i-1}^n, t_i^n)$,
\[
\mathbb{E}[|\Delta \tilde{V}_n|^2] \leq \mathbb{E}[|\Delta V_{t_{i-1}^n}^n|^2] + C_5 \Delta_n^2 + C_5 \int_{t_{i-1}^n}^t \mathbb{E}[|\Delta \tilde{V}_n|^2] \, ds. \quad (80)
\]

Hence by Gronwall’s lemma we have that for all $t \in [t_{i-1}^n, t_i^n)$,
\[
\mathbb{E}[|\Delta \tilde{V}_n|^2] \leq \exp(C_5(t - t_{i-1}^n)) \left( \mathbb{E}[|\Delta V_{t_{i-1}^n}^n|^2] + C_5 \Delta_n^2 \right)
\]
\[
\leq \exp(C_5 \Delta_n) \left( \mathbb{E}[|\Delta V_{t_{i-1}^n}^n|^2] + C_5 \Delta_n^2 \right), \quad (81)
\]

which leads to, by plugging the inequality (81) in (80), that for all $t \in [t_{i-1}^n, t_i^n)$,
\[
\mathbb{E}[|\Delta \tilde{V}_n|^2] \leq \mathbb{E}[|\Delta V_{t_{i-1}^n}^n|^2] + C_5 \Delta_n^2 + C_5 \Delta_n \exp(C_5 \Delta_n) \left( \mathbb{E}[|\Delta V_{t_{i-1}^n}^n|^2] + C_5 \Delta_n^2 \right)
\]
\[
\leq \mathbb{E}[|\Delta V_{t_{i-1}^n}^n|^2] \left( 1 + C_5 \Delta_n \exp(C_5 \Delta_n) \right) + C_5 \Delta_n^2 + C_5^2 \Delta_n^3 \exp(C_5 \Delta_n). \quad (82)
\]

Therefore there exists a constant $C_6 > 0$ such that for all $t \in [t_{i-1}^n, t_i^n)$,
\[
\mathbb{E}[|\Delta V_{t_{i-1}^n}^n|^2] \leq \mathbb{E}[|\Delta V_{t_{i-1}^n}^n|^2](1 + C_6 \Delta_n) + C_6 \Delta_n^2. \quad (82)
\]

Let $(\tau_k^{i,n})_{k \in \mathbb{N}}$ a non-decreasing sequence such that $\lim_{k \to +\infty} \tau_k^{i,n} = t_i^n$, by Fatou’s lemma we have
\[
\mathbb{E} \left[ \liminf_{k \to +\infty} |\Delta \tilde{V}_{\tau_k^{i,n}}|^2 \right] \leq \liminf_{k \to +\infty} \mathbb{E}[|\Delta \tilde{V}_{\tau_k^{i,n}}|^2] \leq \mathbb{E}[|\Delta V_{t_{i-1}^n}^n|^2](1 + C_6 \Delta_n) + C_6 \Delta_n^2,
\]

47
\[
\mathbb{E}\left[\lim_{k\to+\infty}\left|\Delta \tilde{V}_{n_k}^n\right|^2\right] = \mathbb{E}\left[\lim_{k\to+\infty}\left|\Delta \tilde{V}_{n}^n\right|^2\right] = \mathbb{E}\left|\Delta V_{n}^n\right|^2
\]

since \(\lim_{t\to(t^n_i)^-}\Delta \tilde{V}_{t}^n = \Delta V_{t}^n\). Therefore we have for all \(n \in \mathbb{N}^*, i \in [1, n]\),

\[
\mathbb{E}[|\Delta V_{t_{i-1}}^n|^2] \leq \mathbb{E}[|\Delta V_{t_{i-2}}^n|^2](1 + C_6 \Delta_n) + C_6 \Delta_n^2
\]

\[
\leq \mathbb{E}[|\Delta V_{t_{i-2}}^n|^2](1 + C_6 \Delta_n)^2 + C_6 \Delta_n^2(1 + C_6 \Delta_n) + C_6 \Delta_n^3
\]
\[
\vdots
\]
\[
\leq \mathbb{E}[|\Delta V_{t_0}^n|^2](1 + C_6 \Delta_n)^i + C_6 \Delta_n^2 \sum_{k=0}^{i-1} (1 + C_6 \Delta_n)^k.
\]

Considering the fact that \(\Delta V_{t_0}^n = 0\), we have for all \(n \in \mathbb{N}^*, i \in [1, n]\),

\[
\mathbb{E}[|\Delta V_{t_{i-1}}^n|^2] \leq C_7 \Delta_n^2 \sum_{k=0}^{i-1} (1 + C_6 \Delta_n)^k.
\]

Hence there exists a constant \(C_7 > 0\) such that for all \(n \in \mathbb{N}^*, i \in [0, n]\),

\[
\mathbb{E}[|\Delta V_{t_{i-1}}^n|^2] \leq C_7 \Delta_n
\]

and for all \(n \in \mathbb{N}^*, i \in [0, n], t \in [t_{i-1}^n, t_i^n]\),

\[
\mathbb{E}[|\Delta V_{t}^n|^2] \leq \mathbb{E}[|\Delta V_{t_{i-1}}^n|^2](1 + C_3 \Delta_n) + C_3 \Delta_n
\]
\[
\leq C_7 \Delta_n(1 + C_3 \Delta_n) + C_3 \Delta_n
\]
\[
= O(\Delta_n)
\]

which implies that there exists a constant \(C_8 > 0\) such that for all \(n \in \mathbb{N}^*, i \in [1, n]\),

\[
\sup_{t \in [t_{i-1}^n, t_i^n]} \mathbb{E}[|\Delta V_{t}^n|^2] \leq C_8 \Delta_n.
\]

This gives that for all \(n \in \mathbb{N}^*,\)

\[
\sup_{t \in [0,T]} \mathbb{E}[|\Delta V_{t}^n|^2] = \max_{1 \leq i \leq n} \sup_{t \in [t_{i-1}^n, t_i^n]} \mathbb{E}[|\Delta V_{t}^n|^2] \leq C_8 \Delta_n.
\]
