#### Abstract

Monte-Carlo tree search is a powerful paradigm for full information games. We present various changes applied to this algorithm to deal with the stochastic game Chinese Dark Chess. We experimented with group-nodes and chance-nodes using various configurations: with different playout policies, with different playout size, with true or evaluated wins. Results show that extending playout size over the real draw condition is beneficial to group-nodes and to chance-nodes. It also shows that using evaluation function can reduce the number of draw games with group-nodes and can be increased with chance-nodes.

## 1 Introduction

Chinese Dark Chess (CDC) is a popular stochastic two players game in Asia that is often played on $4 \times 8$ rectangular board where players do not know flipping moves' payoff. The two player (called black and red) start with the same set of pieces: one king, two guards, two bishop, two knights, two rooks, two cannons and five pawns (pieces that are similar to Chinese Chess). Before the first move, players do not know their color. The first player move defines the first player color. In classical games, pieces evolve on squares and can move vertically and horizontally from one square to an adjacent free square (i.e up, down, left and right). A piece can capture another piece according to pieces value. Captures are done on vertical and horizontal adjacent squares except for cannons that capture pieces by jumping over another piece. Such jump is done over a piece (called the jumping piece) and to the target piece. Free spaces can stand between its initial position and the jumping piece and between the jumping piece and the target position. Even if flipping moves imply multiple board possibilities, classical moves can lead to similar positions during the game and capturing rules are different for each piece, MonteCarlo Tree Search (MCTS) programs have been recently improved as best. We show in this paper two different MCTS implementations that can be further improved using longer playouts, playing policies playout and heuristic playout.

Section 2 describes related works. Section 3 presents two MCTS implementations. Section 4 shows experimental results achieved with different playout size, playout policies and playout evaluation functions. At the end, section 5 concludes.

## 2 Related works

In this section we expose related works on CDC. Even if there are few works on this game, previous works concern alpha-beta, move policies, endgame databases and MCTS.

Chen et al. [1] used alpha-beta algorithm with different revealing policies combined with a initial-depth flipping method to reduce the branching factor. They distinguished opening, middle and endgame to apply different policies.

Chen et al. [2] built an endgame databases with retrograd analysis. Created databases are done for each first move color, up to 8 revealed pieces. They used 2 TB of memory to represent $10^{12}$ positions. Positions status are stored as win, lost or draw.

Yen et al. [3] presented a non-deterministic Monte Carlo tree search model by combining chance nodes [4] and MCTS. They create shorter simulation by moderating the three policies named Capture First, Capture Stronger Piece First and Capture and Escape Stronger Piece First. As draw rate decreases, win rate increases and simulations are more meaningful for MCTS.

Chang and Hsu [5] solved the 2 x 4 variant. They created a Oracle variant where every pieces are known. Comparing the Oracle variant and the classical variant shows that the first move is crucial on 2 x 4 board.

Chen and Hsu [6] presented a policy-oriented search method to build opening books in case of very large state space as it is in CDC. Attack, defend, claim or discover territory are compared according to player's turn. Results show that player's level is a little stronger with openings. As flipping moves can completely change the game issue, they showed that enhancements provided are probabilistically acquired.

Safidine et al. [7] exploit pieces combinations to reduce endgame databases. By combining material symmetry identified by relations between pieces and endgames building with retrograd analysis, winning positions are recorded in databases. This general method has been applied to Skat, Dominoes and CDC. Even if relationship between pieces in CDC creates intricate symmetries, they reduced the size of 4 elements endgame tables by 9.92 and the size of 8 elements endgame tables by 3.68 .

Chen et al. [8] present equivalence classes computation for endgames with unrevealed pieces. Boards are identified by threats and pieces' positions that are compared in a multiple steps algorithm. Compression rates of material has been studied from 3 to 32 pieces. Endgames database has been computed with 3 to 8 pieces and its number of element is reduced by 17.20 .

Move groups have been proposed in [9] to address the problem of MCTS in games with a high branching factor. When there are too many moves, it can be a good heuristic to regroup the statistics of moves that share some properties. For example in the game of Amazons where the branching factor can be of the order of a thousand of moves a natural way to reduce the branching factor is to separate the queen move from the stone placement. In the imperfect information game Dou Di Zhu, Information Set [10] has been combined with move groups: the player first chooses the base move and then the kicker, as two separate
consecutive decision nodes in the tree. Move groups have also been analyzed on an abstract game [11].

## 3 Stochastic MCTS

In this section, we present the use of chance-nodes and of group-nodes with MCTS. Group-nodes are used to reduce the branching factor created by flipping moves. In a similar manner to move groups that regroup moves, we define groupnodes to consider all revealing moves at the same position in a single node. Apart from that, chance-nodes are the classical way to manage stochastic information in trees. We present the main loop and the selection function of MCTS with group-nodes and with chance-nodes. Both algorithms are presented as anytime interruptible process, that tend to produce better solution over computing time and that are instantaneously interrupt when time is up or when a winning move is found.

### 3.1 With group-nodes

During the game, applying a flipping move can conduct to different boards. At the beginning of the game, the first player has 32 possible moves that correspond to $4 * 10^{36}$ possibilities. During the game, the number of possible boards linked to flipping moves decreases with the number of unrevealed pieces. For the penultimate flipping move, 2 boards are possible and for the last flipping move, only one board. But as the number of possible boards stays over 120 for more than 5 different pieces, the number of possible boards remains important at most of the time before endgame. To reduce the number of children node produced by flipping moves, all possible boards that arise from a flipping move are gathered in single group-node. Therefore, at the beginning of the game, the root node is followed by 32 children that are group-nodes. Then other actions (moves, jumps and captures) are represented in the tree with classical nodes. The main loop of MCTS with group-nodes is presented in Alg 1. The selection phase (line 2) returns a node $q$ to expand, its corresponding board and $\mathcal{L}$ the list of moves to apply for expansion. By default, all nodes inserted in the tree have UNSET winning color. If this node is known as winning position, the process is interrupted (line 3). Otherwise each element of $\mathcal{L}$ creates a new child to $q$ and store it in $\mathcal{N}$. For each element of $\mathcal{N}$, the board is modified, a new simulation is applied from the modified board and a new result is backpropagate from the new node up to the root_node. At the end, the bestNext function selects the best next node $q_{b e s t}$ of the root_node that defines the best next move.

The selection function of MCTS with group-nodes is presented in AlG 2. The process iterates to find the best node $q$, its corresponding board and its moves $\mathcal{M}$. There are 4 different cases:
$-q$ is known as winning position. Then the process is interrupted (line 5).
$-q$ is leading a player to a new winning position. Then it returns $q$ with the corresponding board and an empty set (line 7).

```
Algorithm 1 MCTS with group-nodes
    while not-interrupted do
        \((q\), board, \(\mathcal{L}) \leftarrow\) select ()
        if q.winning_color \(!=U N S E T\) then break
        \(\mathcal{N} \leftarrow\) expandAll \((q, \mathcal{L})\)
        for each \(e \in \mathcal{N}\) do
            board \({ }^{\prime} \leftarrow\) applyMove \((e\), board \()\)
            simulate ( \(e\), board')
            backpropagate (e)
        end for
    end while
    \(q \leftarrow\) bestNext (root_node)
    return \(q\)
```

$-q$ is a new node that has not been extended previously. Then it returns $q$ with the corresponding board and new moves that corresponds to the board (lines 9 to 11).
$-q$ is a group-node previously evaluated with a different flipping outlet that produces new moves that are not yet considered in $q$ children. Then it returns $q$ with the corresponding board and new moves that corresponds to only previously unconsidered moves in $q$ group-node (line 13 to 15).

The next function (Alg 2 line 6) returns all current next nodes of $q$. The move function (line 8) returns all next moves of the current board. If $\mathcal{M}$ is empty (line 9), the corresponding node is noted as winning node for the opponent player of the current board turn. The test applied line 13, checks if the current situation fits with the current group-node. If it fits, then the best_next function is applied to select the best nodes inside $\mathcal{M}$ (line 17). If it does not fit, then the selection process is stopped and $\mathcal{M}$ becomes a set of previously unconsidered moves (line 14).

### 3.2 With chance-nodes

During the game, moves can conduct to the creation of chance-nodes. As different pieces are unknown, each flipping move is represented with a chance-node. Other board modifications, like moves, jumps and captures, are represented with classical nodes. Chance-nodes are composed of classical nodes. At a chance-node, each flipping possibility corresponds to a new child. The main loop of MCTS with chance-nodes is presented in Alg 3.

According to UCT formulae, this process applies iteratively selection, simulation and backpropagation. From a selected node $q$, the simulation leads to a new node $q_{\text {new }}$ from which the result of the last simulation is backpropagate toward the root_node. At the end, the bestNext function selects the best next node $q_{b e s t}$ of the root_node that defines the best next move. The selection of a chance node can lead to different boards and the selection of a classical node leads to an expected situation. At the beginning, all nodes are inserted in the

```
Algorithm 2 select () with group-nodes
    \(q \leftarrow\) root
    board \(\leftarrow\) root_board
    \(\mathcal{M} \leftarrow \emptyset\)
    while not-interrupted do
        if \(q\).winning_color \(!=U N S E T\) then break
        \(\mathcal{N} \leftarrow \operatorname{next}(q)\)
        if size \((\mathcal{N})=0\) then break
        \(\mathcal{M} \leftarrow\) moves (board)
        if size \((\mathcal{M})=0\) then
            q.winning_color \(\leftarrow\) opponent (board.turn)
            break
        end if
        if \(\exists e \in \mathcal{M}\) with \(e \notin \mathcal{N}\) then
            \(\mathcal{M} \leftarrow \mathcal{M}-(\mathcal{M} \cap \mathcal{N})\)
            break
        end if
        \((q\), board \() \leftarrow\) best_next \((q, \mathcal{M})\)
    end while
    return ( \(q\), board, \(\mathcal{M}\) )
```

```
Algorithm 3 MCTS with chance-nodes
    while not-interrupted do
        ( \(q\), board) \(\leftarrow\) select ( )
        if \(q_{\text {new }}\).winning_color \(!=U N S E T\) then break
        \(q_{\text {new }} \leftarrow\) simulate ( \(q\), board)
        backpropagate ( \(q_{\text {new }}\) )
    end while
    \(q_{\text {best }} \leftarrow\) bestNext (root_node)
    return \(q_{b e s t}\)
```

tree without winning color information. If the selected node is a winning node, the process can be immediately interrupted (line 3 Alg 3 and line 4 Alg 4).

```
Algorithm 4 select ( ) with chance-nodes
    \(q \leftarrow\) root
    board \(\leftarrow\) root_board
    while not-interrupted do
        if \(q\).winning_color \(!=U N S E T\) then break
        \(\mathcal{M} \leftarrow\) moves (board)
        if size \((\mathcal{M})=0\) then
            q.winning_color \(\leftarrow\) opponent (board.turn)
            return ( \(q\), board)
        end if
        if \(\left(\operatorname{pos}_{i}, \operatorname{pos}_{f}\right) \leftarrow\) newMove \((q\), board, \(\mathcal{M})\) then
            if \(\left(p o s_{i}=p o s_{f}\right)\) then
                \(q^{\prime} \leftarrow\) addChanceNode \((q)\)
            \(q_{\text {new }} \leftarrow\) addNode \(\left(q^{\prime}\right)\)
            else
            \(q_{\text {new }} \leftarrow\) addNode ( \(q\) )
            end if
            board \(\leftarrow \operatorname{play}\left(\right.\) pos \(_{i}\), pos \(\left._{f}\right)\)
            return ( \(q_{\text {new }}\), board)
        end if
        \((q\), board \() \leftarrow\) best \((q\), board, \(\mathcal{M})\)
    end while
```

The selection function of MCTS with chance-nodes is presented in Alg 4. The process iterates to find the best node $q$ and its corresponding board. From the root_node and the root_board, the current board is updated according to the best move. At each iteration, a set of moves $\mathcal{M}$ is defined according to the selected board position and its turn. If this set is empty (line 6), the corresponding node is noted as winning node for the opponent player of the current board turn. If the best move is a new flipping move (line 11), a new chance node and a new node are added in the tree. If initial and final positions differ, a simple classical node is added.

## 4 Experiments

In this section, we present various experiments to select fastest policies, to reduce draw endgames, with varying playout size, with or without evaluation function.

### 4.1 Fastest policies

In this section, we present various policies used to enhance playouts. We present basic and advanced ones and evaluate them to be useful in MCTS with as fast
simulations as possible. The fastest policies are considered as most promising and are selected to continue our study.

We have used 4 basic playout policies, that are natural to use in CDC :

- Random, where players play randomly.
- Capture, where players try to capture opponent pieces.
- Avoid, where players try to avoid opponent's capture.
- Trap, where players try to minimize opponents moves.

According to these basics policies, we settled 4 advanced policies declined from the basics:

- Capture and avoid, where players try first to capture one opponent, try second to avoid opponents and otherwise play randomly.
- Avoid and capture, where players try first to avoid opponents, try second to capture one opponent and otherwise play randomly
- Capture and trap, where players try first to capture one opponent and otherwise to trap opponents.
- Capture avoid and trap, where players try first to capture an opponent, try second to avoid opponents and otherwise to trap opponents.

All these policies have been tested for 2000 playouts at the beginning, the middle and the end of the game. Results are shown in Fig. 1-3 and in Tab. 1.

Fig. 1 show the board at the beginning of the game, when player colors are unknown. Best moves are colored in gray on the board and are bold in Tab. 1.

Fig. 1: Beginning.

Fig. 2: Middlegame.

Fig. 3: Endgame.

Table 1: Playing 2000 playouts at beginning, middle game and endgame.

| Policy | Time | Rem. pieces | Playout size | Without eval. fun. |  |  | With eval. fun. |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Best\| | W | L D | Best | W | L | D |
| At beginning |  |  |  |  |  |  |  |  |  |  |
| Random | 0.660 | $12.16{ }_{\text {(2.31) }}$ | 106.37 (9.25) | d7 | - | - 100 | b7 | 69 | 30 | 01 |
| Capture | 0.375 | 5.67 (2.20) | $100.01 \quad$ (17.69) | c2 | 25 | $22 \quad 53$ | b3 | 52 | 48 |  |
| Avoid | 5.973 | $16.78{ }_{(2.88)}$ | 207.41 (74.49) | b2 | - | 100 | c8 | 57 | 43 |  |
| Capture and avoid | 0.598 | $7.24{ }_{\text {(2.25) }}$ | 107.27 (18.05) | b1 | 34 | 1353 | c8 | 55 | 45 |  |
| Avoid and capture | 1.049 | 7.69 (2.20) | 123.02 (20.15) | c4 | 18 | 0676 | c6 | 38 | 60 | 02 |

| At midlle game |  |  |  |  |  |  |  |  |  |  |
| Random | 0.606 | $12.18{ }_{(2.24)}$ | 91.89 (9.20) | d8 |  | - 100 | c6-c7 | 43 | 57 |  |
| Capture | 0.348 | $6.91{ }_{(2.17)}$ | 75.60 (19.26) | c6-c7 | 48 | 0250 | c6-c7 | 90 | 10 |  |
| Avoid | 5.072 | $16.60{ }_{(2.72)}$ | 194.68 (87.18) | d4 | - | - 100 | d4 | 55 | 44 | 01 |
| Capture and avoid | 0.585 | 7.53 (1.96) | 89.06 (17.93) | c6-c7 | 34 | 0264 | c6-c7 | 84 | 16 | - |
| Avoid and capture | 0.885 | 7.55 (2.02) | 103.68 (15.79) | c6-c7 | 04 | 1482 | c6-c7 | 30 | 69 | 01 |
| Trap | 157.911 | 9.68 (1.86) | 704.73 (62.78) | d7 |  | - 100 | d8 | 97 | 03 | - |
| Capture and trap | 123.055 | $14.49{ }_{(2.89)}$ | 711.58 (45.01) | b8 | 01 | - 99 | d4 | 76 | 24 | - |
| Capture avoid and trap | 34.201 | 9.92 (1.59) | 370.29 (177.85) | c6-c7 | 54 | $00 \quad 46$ | c6-c7 | 10 |  |  |
| At endgame |  |  |  |  |  |  |  |  |  |  |
| Random | 0.504 | 8.23 (1.14) | 42.72 (1.46) | a8-a7 | - | - 100 | a8-a7 | - | 100 | - |
| Capture | 0.469 | 6.26 (0.94) | 41.93 (6.02) | a8-a7 | 00 | 2278 | a8-a7 | - | 100 | - |
| Avoid | 0.781 | 10.12 (0.54) | 40.66 (1.55) | d2-c2 | - | 0298 | d2-c2 | - | 100 | - |
| Capture and avoid | 0.733 | 8.00 (0.00) | 43.00 (0.00) | a8-a7 | - | - 100 | a8-a7 | - | 100 | - |
| Avoid and capture | 0.817 | 9.80 (0.53) | 40.34 (4.36) | d2-c2 | - | 0496 | d2-c2 | - | 100 | - |
| Trap | 11.138 | 7.00 (0.00) | 44.00 (0.00) | d2-c2 | - | - 100 | d2-c2 | - | 100 | - |
| Capture and trap | 7.389 | 11.00 (0.00) | 40.00 (0.00) | d2-c2 | - | - 100 | d2-c2 | - | 100 |  |
| Capture avoid and trap | 6.030 | 8.0 (0.00) | $43.00_{(0.00)}$ | a8-a7 | - | - 100 | a8-a7 | - | 100 | - |

Fig. 2 shows the resulting board situation after the following 10 turns. Unknown pieces are represented with white circles. The 10 moves played are (columns are annotated with letters and rows are annotated with numbers. Flipping moves indicate a revealed piece under parenthesis. Moving and capturing moves indicate two coordinates. ) :
c4(k) d1 (P) ; d2(N) d5(p) ; c2(G) c3(c) ; c5(C) c5-c3 ;
c4 (p) c6(M) ; b3(r) c6-c5 ; b3-c3 c2-c3 ; c7(C) c5-d5 ;
b6(g) d5-c5 ; b6-c6 b7(G) ;
It is now first player's turn to play. 19 reveal moves remain. First player is black and its non-flipping possible moves are :
b4-b3 ; c6-b6 ; c6-c7 ; c6-c5 ;
Second player is white (i.e. red) and its non-flipping possible moves are :
b7-b6 ; c5-c4 ; c5-d5 ; c3-b3 ; c3-c2 ; c3-c4 ; d2-c2 ;
First player has captured only one C piece and second player has captured 3 pieces that are p c r. Good move for black is c6-c5, or reveal c8 and d7.

Fig. 3 shows an endgame board, where everything is known. Black has clearly lost the game.

As CDC games can end in a draw, we settled an evaluation function that can evaluate a draw board. This evaluation is based on the material that is remaining on the board for one player over its opponent. It allows to assign numerical value to draw endgame boards. As we do not know if playing first is an advantage, we allow this evaluation to reply draw if material are equivalent.

In some specific cases, draw depends on pieces position and then this function gives false win detection. In order, pieces $\{\mathrm{K} G \mathrm{M} \mathrm{R} \mathrm{N} \mathrm{C} \mathrm{P}\}$ are associated to $\{0.15,0.1,0.07,0.05,0.03,0.05,0.05\}$.

Tab. 1 compares the time needed by basic and advanced policies to achieve 2000 playouts. This table also gives the average of remaining pieces and its standard deviation, the average playout size and its standard deviation, best moves with and without evaluation function.

It shows that some policies are too slow (i.e. Avoid, Avoid and capture, Trap, Capture and trap, Capture avoid and trap) to play a significant number of playouts to be simply used in MCTS. Remaining pieces and playout size showed us that longer playout could be interesting.

### 4.2 Reducing draw endgames

In this section, we select the best policies by checking their ability to create as less draw endgames as possible. Results are presented according to various draw conditions.

As some policies are considered as too slow, we only kept Random (i.e. RND), Capture (i.e. CAP_RND), Capture and avoid (i.e. CAP_AVD_RND) and Avoid and Capture (i.e. AVD_CAP_RND) (where these three last also call random if nothing has been done first).

Table 2: Applying 2000 playouts from beginning board.

| Policy | time[sec] | draw | Rem. pieces | Playout size | Draw condition |
| :--- | ---: | ---: | ---: | ---: | ---: |
| RND | 0.630 | 1.00 | 12.62 | 106.07 | 40 |
|  | 1.067 | 0.99 | 6.03 | 232.11 | 160 |
|  | 1.801 | $\mathbf{0 . 6 7}$ | 3.24 | 622.37 | 640 |
| CAP_RND | 0.376 | 0.70 | 5.66 | 103.71 | 40 |
|  | 0.522 | 0.46 | 4.59 | 171.77 | 160 |
|  | 0.802 | $\mathbf{0 . 3 1}$ | 4.29 | 335.92 | 640 |
| CAP_AVD_RND | 0.598 | 0.73 | 7.15 | 110.45 | 40 |
|  | 0.953 | 0.53 | 6.07 | 185.41 | 160 |
|  | 2.139 | $\mathbf{0 . 4 3}$ | 5.87 | 403.44 | 640 |
| AVD_CAP_RND | 1.012 | 0.87 | 7.77 | 124.29 | 40 |
|  | 1.707 | 0.69 | 6.19 | 223.51 | 160 |
|  | 4.353 | $\mathbf{0 . 5 9}$ | 5.85 | 550.41 | 640 |

Tab. 2 shows the time used to generate 2000 playouts from the beginning board. Next columns show the draw ratio, the average number of pieces at the end, the playout size according to different draw conditions. In a normal game, the draw condition is equal to 40 moves without capture or reveal. It shows that the number of draw can be reduced significantly by increasing the draw condition. In the same time, the number of remaining pieces are reduced. It shows that CAP_RND is really efficient for very important value of draw condition. We decided to eliminate the AVD_CAP_RND policy that increases the time with fewer draw than simple RND policy.

### 4.3 Group-nodes vs. chance-nodes

In this section, we challenge MCTS players by facing group-nodes against chancenodes, with different playout size, with most promising policies. For each combination, we also checked the evaluation influence in helping MCTS formulae to select better player. All the player are tested against a reference player, that simply plays randomly when pieces are unrevealed and otherwise applies minimax to find the best move. Results are shown in Tab. 3 for 500 games with half as first player and half as second player. Each player has 1 sec to generate a new move. The corresponding number of draw games are shown in Fig. 4 for MCTS with group-nodes and in Fig 5 for MCTS with chance-nodes.

Table 3: Playing 500 games against reference player.

| chance-nodes | playout size | 40 |  | 160 |  | 640 |  | 2560 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | win | lost | win | lost | win | lost | win | lost |
|  | C2-R | 0 | 255 | 4 | 298 | 213 | 109 | 164 | 72 |
|  | C2-R-h | 9 | 137 | 104 | 64 | 116 | 43 | 135 | 42 |
|  | C2-CR | 244 | 16 | 242 | 21 | 245 | 15 | 149 | 21 |
|  | C2-CR-h | 131 | 15 | 143 | 14 | 138 | 23 | 129 | 23 |
|  | C2-CAR | 199 | 33 | 245 | 27 | 239 | 46 | 159 | 47 |
|  | C2-CAR-h | 129 | 16 | 125 | 25 | 122 | 9 | 104 | 30 |
| group-nodes | playout size | 40 |  | 160 |  | 640 |  | 2560 |  |
|  |  | win | lost | win | lost | win | lost | win | lost |
|  | C1-R | 10 | 249 | 51 | 185 | 78 | 187 | 64 | 233 |
|  | C1-R-h | 60 | 269 | 103 | 231 | 80 | 219 | 85 | 263 |
|  | C1-CR | 35 | 46 | 101 | 52 | 146 | 61 | 137 | 66 |
|  | C1-CR-h | 120 | 87 | 167 | 98 | 182 | 88 | 147 | 127 |
|  | C1-CAR | 41 | 35 | 103 | 52 | 128 | 93 | 72 | 170 |
|  | C1-CAR-h | 109 | 100 | 167 | 86 | 175 | 97 | 130 | 143 |

The RND policy is now abbreviate with R, the CAP_RND policy is abbreviate CR and the CAP_AVD_RND) policy is abbreviate CAR. C1 stands for group-nodes and C 2 stands for chance-nodes. h mentions evaluation function usage and no h means that only true victories are considered inside playouts.

Results shows that chance-nodes are less effective with evaluation function where group-nodes are more effective with evaluation function. It further shows that chance-nodes are more dependant on playout size than group-nodes. Best group-nodes players achieved 182 and 175 victories when chance-nodes achieved 244 and 245 victories.

For each policy, Fig 4 shows that evaluation function reduces the number of draw games with group-nodes. Nonetheless the number of draw games is equal or more important with chance-nodes (see Fig 5).

Table 4: Tournament between UCT players.

|  | C1-CAR-h-640 | C2-CR-40 | C2-CR-640 | C2-CAR-160 |
| :--- | ---: | ---: | ---: | ---: |
| C1-CR-h-640 | $\mathbf{2 6 8} / 169$ | $\mathbf{2 8 2} / r 97$ | $176 / \mathbf{2 5 2}$ | $287 / 131$ |
| C1-CAR-h-640 |  | $\mathbf{2 2 8} / 137$ | $156 / \mathbf{2 8 5}$ | $236 / 175$ |
| C2-CR-40 |  |  | $149 / \mathbf{2 2 0}$ | $176 / 204$ |

Fig. 4: Group-node draw of TAB 3

Fig. 5: Chance-node draw of TAB 3

Tab. 4 presents a tournament of best chance-nodes and group-nodes players. It shows that :

- Between group-nodes, CR-h-640 (i.e. Capture with evaluation function and playout size of 640) is the best policy.
- Chance-nodes even simply with Capture policy are better than group-nodes.
- Between all players, the best is chance-nodes with Capture, without evaluation function and with playout size of 640 .

It shows that sophisticated policies are better with group-nodes where the basic Capture policy is the best with chance-nodes. Extending playout size over the real draw condition is beneficial to group-nodes and to chance-nodes.

## 5 Conclusion

We have presented different Monte-Carlo tree search that deal with the stochastic game Chinese Dark Chess. We have shown relations with playout size, basic or advanced policies and evaluation function usage. While extending the playout size is useful to create more inform playouts, an evaluation function usage can increase or decrease player's effectiveness through modifying the number of draw possibilities.
