We inspect the influence of the spacing on the resonance of a periodic arrangement of Helmholtz resonators. An effective problem is used which captures accurately the properties of the resonant array within a large range of frequency, and whose simplified version leaves us with an impedance condition. It is shown that the strength of the resonance is enhanced when the array becomes sparser. This degree of freedom on the radiative damping is of particular interest since it does not affect the resonance frequency nor the damping due to losses within each resonator; besides, it does not affect the total thickness of the array. We show that it can be used for the design of a perfect absorbing walls.

I. INTRODUCTION

Originally studied for their musical properties [1], the Helmholtz resonators are the most classical resonators for the acoustic waves. When organized in two or three dimensional arrays, they are known to have a collective behavior which has been used for several applications, including the improvement of edifice sonority [2] or to the opposite the reduction of noises in ventilation systems or in aircraft engines [3]. With the development of meta-materials, it has been promoted to a key piece in devices as perfect absorbers efficient in the low frequency regime [4, 5], or devices acting beyond the diffraction limit, as superlenses [6] or sensors [7] designed at the subwavelength scale [8, 9].

Such resonators have been largely studied using approximate modal methods [10, 11]. Nowadays, the most popular model for an array of Helmholtz resonators consists in applying a condition of the Robin type on a plane at the top of the necks. The acoustic pressure p is linked to the normal velocity v on this plane through the condition $p = -Zv$. The so-called wall impedance Z encapsulates a frequency dependence chiseled to properly account for the lowest resonance. Chiseled means that the initial approximated modal result has been improved using physical arguments. This leads to the notion of added length entering in the expression of Z which accounts for the contribution of the near field [10], and to the addition of an imaginary part to Z which accounts for the viscothermal losses [12]. Beyond the parameters of a single resonator in the array (geometry of the cavity and of the neck), the array spacing h is of particular interest since it does not affect the thickness $(d + e)$ of the whole device (Fig. 1). Often, when h becomes larger than the dimensions of a single resonator, discrete models are preferred. This may lead to discrete potential problem (Kronig-Penney system), see [13, 14] for one dimensional

FIG. 1: Array of Helmholtz resonators. Each resonator has dimensions (d, e, h_c, h_n) , and we define the aspect ratios $\varphi_c = h_c/h$ for the cavity and $\varphi_n = h_n/h$ for the neck. A compact array corresponds to $h_c \sim h$, a sparse array to $h_c \ll h$.

array, or to discrete network problem in two-dimensions [15]. In previous studies, we presented a homogenized model able to accurately reproduce the behavior of such arrays up to unexpected high frequencies $kh \sim 2\pi$, that is which is limited only by the appearance of higher orders of diffraction [16, 17]; a similar approach is presented in [18], see also [19].

In this paper, we use this model to study the influence of the array spacing, from compact to sparse arrays. In its complete form, the effective model provides a comprehensive picture of the wave pattern inside the resonators (in particular the pressure amplitude is correctly predicted), and it can be simplified to a wall impedance model (where the resonators have disappeared); this is presented in Section II. We shall see that the strength of the resonance can be tuned by the spacing h (Section III). Intuitively, the resonance of a resonator within a sparse array is close to that of a single one and it turns out that the collective effect of closer resonators weakens their resonance. This provides a degree of freedom to tune the radiative damping without affecting the damping due to the losses, this latter being related to the geometry of a

single resonator, not to the array spacing. Thus, when the losses are accounted for, the two dampings can be tuned independently to reach the so-called critical coupling condition realizing perfect absorption (Section IV).

II. THE HOMOGENIZED MODEL - TOWARD AN IMPEDANCE CONDITION

A. The complete homogenized problem

The homogenization of the array of Helmholtz resonators (Fig. 2(a) - (b)) has been detailed in [17]. To capture the leakage of the resonance, the propagation inside the region of the cavities is taken into account, and this provides an equivalent anisotropic medium replacing that region. There, the wave equation reads as

$$\frac{\partial^2 p}{\partial y^2} + k_c^2 p = 0, \quad (1)$$

where k_c is the wavenumber in the cavities, being possibly complex when the losses are accounted for (and $k_c = k$ in the lossless case). The acoustic velocity $\mathbf{u} = (u, v)$ reads

$$\mathbf{u} = \begin{pmatrix} 0 & 0 \\ 0 & \varphi_c \end{pmatrix} \nabla p. \quad (2)$$

As expected, we find that the propagation is not allowed in the direction perpendicular to the vertical rigid walls ($u = 0$) and the velocity along y is $v = \varphi_c \partial_y p$. This result anticipates that the continuity of the velocity, which applies in the actual problem, has been replaced by the continuity of the flow-rate in the homogenized problem. Eventually, the effect of the necks is encapsulated in non intuitive jump conditions, namely

$$[[p]] = h\mathcal{B}\bar{v}, \quad [[v]] = -h\mathcal{C} \frac{\partial^2 \bar{p}}{\partial x^2} - e\varphi_n k_n^2 \bar{p}. \quad (3)$$

In the above expressions, we have defined the jump of f being $[[f]] \equiv f|_{y=0} - f|_{y=-e}$, and its mean value $\bar{f} \equiv \frac{1}{2}(f|_{y=0} + f|_{y=-e})$. Then, k_n refers to the wavenumber in the neck, being possibly complex valued in the lossy case (and $k_n = k$ otherwise).

In principle, the interface parameters $(\mathcal{B}, \mathcal{C})$ are deduced from elementary problems (typically of potential flows) that have to be solved numerically and we provide scripts to calculate them in the Appendix A. In addition, good estimates of $(\mathcal{B}, \mathcal{C})$ are given by

$$\begin{cases} \mathcal{B} \simeq \frac{e}{h\varphi_n} - \frac{1}{\pi} \log \left(\sin \left(\pi \frac{\varphi_n}{2} \right) \sin \left(\pi \frac{\varphi_n}{2\varphi_c} \right) \right), \\ \mathcal{C} \simeq \frac{\pi}{16} \varphi_n^2, \end{cases} \quad (4)$$

see Figs. 3 (these coefficients are given in [16], note however a misprint for $\mathcal{C}$ in this reference). Eventually, the boundary condition to be applied at the bottom of

FIG. 2: The problem is set for (a) the actual array of Helmholtz resonators, (b) the equivalent structure in the complete homogenized problem, Eqs. (1-3) and (c) the equivalent surface in the impedance model, Eq. (8) with Z given by (9).

the cavities at $y = -D$ remains the condition of rigid wall (zero normal velocity) which holds all along the anisotropic equivalent medium, see [20], specifically for any x value

$$\frac{\partial p}{\partial y}(x, -D) = 0. \quad (5)$$

FIG. 3: Interface parameters $(\mathcal{B}, \mathcal{C})$; in plain line, deduced from the numerical resolution of the elementary problems (see Appendix A) and in dotted lines given by the closed forms (4).

The Figs. 2(a-b) show the actual problem and the equivalent homogenized one. With the origin at the upper side of the neck, an anisotropic medium fills the region $-D < y < -e$, with $D = d + e$, and the air fills the region $y > 0$. The wave equations read in the two regions

$$\begin{cases} \frac{\partial^2 p}{\partial y^2} + k_c^2 p = 0, & -D < y < -e, \\ \Delta p + k^2 p = 0, & 0 < y, \end{cases} \quad (6)$$

where the losses in the air outside the cavities are neglected. Next, the jump conditions (3) apply between $y = -e$ and $y = 0$ (it is worth noting that the region

$-e < y < 0$ is not questioned) and the boundary condition (5) applies at $y = -D$. Specifically, denoting $p^+ = p(x, 0)$, $p^- = p(x, -e)$ (and the same for v), we have

$$\begin{cases} p^+ - p^- = \frac{h\mathcal{B}}{2}(v^+ + v^-), \\ v^+ - v^- = -\frac{h\mathcal{C}}{2}\left(\frac{\partial^2 p^+}{\partial x^2} + \frac{\partial^2 p^-}{\partial x^2}\right) - \frac{e\varphi_n}{2}k_n^2(p^+ + p^-), \end{cases} \quad (7)$$

where $v^+ = \partial_y p(x, 0)$ and $v^- = \varphi_c \partial_y p(x, -e)$ using (2).

The above system (6-7) involving plane interfaces along x between homogeneous media is a one dimensional problem (along y) for which explicit solutions are available. We shall see in the forthcoming section that this model can be further simplified to get an impedance condition.

B. Toward a homogenized impedance condition

A classical description of an array of Helmholtz resonators consists in imposing, at $y = 0$, an impedance condition (Fig. 2(c)) which links the pressure and the normal velocity in a relation of the Robin type

$$Z = -\frac{p(x, 0)}{v(x, 0)}, \quad (8)$$

with Z the wall impedance. It is shown in the appendix B that neglecting the variations of p^+ and p^- along x allows us to get an impedance of the form

$$Z = \frac{1 - h\mathcal{B}\varphi_c k_c \tan k_c d - \frac{h\mathcal{B}}{4}e\varphi_n k_n^2}{\varphi_c k_c \tan k_c d + e\varphi_n k_n^2 \left(1 - \frac{h\mathcal{B}}{4}\varphi_c k_c \tan k_c d\right)}. \quad (9)$$

This expression does not compare easily to that obtained using approximate modal method, see (C5) derived in Appendix C. However, if we consider the dominant order with $k_n e \ll 1$, we find that the effective length e_{eff} in (C5) has to be chosen as

$$e_{\text{eff}} = h\varphi_n \mathcal{B}, \quad (10)$$

hence for simple neck shape

$$e_{\text{eff}} = e - \frac{h\varphi_n}{\pi} \log \left(\sin \left(\pi \frac{\varphi_n}{2} \right) \sin \left(\pi \frac{\varphi_n}{2\varphi_c} \right) \right), \quad (11)$$

using (4); the extra term corresponds to the so-called added length and it encapsulates the effect of the evanescent field at the extremities of the neck, this is discussed further in [16].

III. SCATTERING OF AN INCIDENT PLANE WAVE - THE LOSSLESS CASE

In this section, we inspect the accuracy of the homogenized model for an incident plane wave in the lossless

case. We have checked that the impedance model using Z in Eq. (9) is as accurate as the complete homogenized model (results are not reported); thus, we refer to the scattering coefficients in the homogenized model indifferently for both versions; obviously, when the wavefield in the region of the cavities is concerned, it corresponds to the complete model (it is not given by the impedance model).

A. Reflection of a plane wave at oblique incidence

1. The complete homogenized model

For an incident wave $p^{\text{inc}}(x, y) = e^{-i\alpha y + i\beta x}$ ($\alpha = k \cos \theta$, $\beta = k \sin \theta$), the solution $p(x, y)$ of the homogenized problem (6-7) reads

$$\begin{cases} p(x, y) = A \cos k_c(y + D)e^{i\beta x}, & -D < y < -e, \\ p(x, y) = [e^{-i\alpha y} + R e^{i\alpha y}] e^{i\beta x}, & 0 < y. \end{cases} \quad (12)$$

Next, (A, R) are obtained applying the jump conditions (7) to (12) and we find that

$$R = -\frac{z_r - iz_i}{z_r + iz_i}, \quad (13)$$

where

$$\begin{cases} z_r = \varphi_c k_c \tan k_c d + (e\varphi_n k_n^2 - h\mathcal{C}\beta^2) \left(1 - \frac{h\mathcal{B}}{4}\varphi_c k_c \tan k_c d\right), \\ z_i = \alpha(1 - h\mathcal{B}\varphi_c k_c \tan k_c d - \frac{h\mathcal{B}}{4}(e\varphi_n k_n^2 - h\mathcal{C}\beta^2)), \end{cases} \quad (14)$$

(as expected, $|R| = 1$ in the lossless case),

$$A = 2k \cos \theta \frac{1 + \frac{h\mathcal{B}}{4}(e\varphi_n k_n^2 - h\mathcal{C}\beta^2)}{z_r + iz_i}, \quad (15)$$

and we denote $A_c = |A|$ the maximum amplitude in the cavities reached at $y = -D$.

2. The impedance model

In the impedance model, the solution is sought in the half plane $y > 0$ only, with

$$p(x, y) = [e^{-i\alpha y} + R e^{i\alpha y}] e^{i\beta x}, \quad 0 < y. \quad (16)$$

and from (8), we get

$$R = -\frac{1 - ikZ \cos \theta}{1 + ikZ \cos \theta}. \quad (17)$$

Expectedly, setting $\mathcal{C} = 0$ or $\beta = 0$ in (13) along with (14) gives (17) along with (9). This is because the term of tangential derivative of the pressure (providing the contribution $h\mathcal{C}\beta^2$) is proportional to the pressure (providing the contribution $e\varphi_n k_n^2$) for an incident plane wave. In general, it is not possible to encapsulate the contribution of the tangential derivative in a Robin condition.

B. From compact to sparse arrays of Helmholtz resonators

We now move to the study of the transition from compact to sparse arrays of resonators. To do so, the geometry of the resonators is kept constant and we vary only their spacing h . The geometry is close to that considered in [4] with $h_c = 1$ cm, and the array working in the kHz regime; next, $d/h_c = 5$, $e/h_c = 0.6$, and $h_c/h_n = 3$.

To begin with, we report in Figs. 4 and 5 the pressure fields and the profiles along the centerline of a resonator for increasing h at incidence $\theta = 40^\circ$ and $kh_c = 0.2$. A comparison between the homogenized solution and that obtained numerically is shown. It is noticeable that the increase in h produces an increase of the pressure in the cavities, and we shall see that this corresponds to sharper resonances.

FIG. 4: Spatial distribution of the pressure field at the first resonance ($kh_c \simeq 0.2$ and $\theta = 40^\circ$); each panel contains the homogenized solution (left half panel) and the solution given by direct numerics (half right panel).

To do so, we report in Figs. 6 the real part of R and A_c against kh_c and h/h_c and in Figs. 7 the profiles for $h/h_c = 1.1$ and 9. The region of low frequency, with a unique order of diffraction, lies below the line $kh(1 + \sin \theta) = 2\pi$ (in dashed line). There, from (13) and (15), R and A are roughly given

$$R \simeq \frac{k \tan kd - \frac{1}{h_c \mathcal{B}} - i\alpha_{\text{RD}}}{k \tan kd - \frac{1}{h_c \mathcal{B}} + i\alpha_{\text{RD}}}, A \simeq \frac{\frac{2}{h_c \mathcal{B} \cos kd}}{k \tan kd - \frac{1}{h_c \mathcal{B}} + i\alpha_{\text{RD}}}, \quad (18)$$

FIG. 5: Profile of pressure along a line containing the centerline of a resonator, from numerics (symbols) and given by the homogenized model (plain lines).

FIG. 6: First two resonances of the array for increasing h/h_c . The resonances $R = -1$ are associated to maximum pressure amplitude in the resonators. Dashed lines delimit the regions with higher diffraction orders $kh(1 + \sin \theta) = 2\pi$ and 4π .

where

$$\alpha_{\text{RD}} = \frac{\tan kd}{h \mathcal{B} \cos \theta}, \quad (19)$$

characterizes the radiative damping. It follows that the resonance at $k = k_H$ is characterized by

$$k_H \tan k_H d = \frac{1}{h_c \mathcal{B}}, \quad A_c \sim \frac{2h}{h_c} \frac{\cos \theta}{\sin k_H d}, \quad (20)$$

(hence $R = -1$). As $h_c \mathcal{B} = \text{Cte} - \frac{h_c}{\pi} \log(\sin(\frac{\pi h_c}{2h}))$ has a logarithm increase with h , the resonance frequency is not significantly impacted by variations of h . To the opposite, from (20) and (18), it is easy to see that $\partial_k R|_{k \simeq k_H}$

FIG. 7: First two resonances of an array of Helmholtz resonators for h/h_c .

and A_c increase linearly with h . Hence increasing h produces sharper variations of R around $k = k_H$ (where $R = -1$) and higher pressures in the cavities, two characteristics of a stronger resonance.

IV. INCLUDING THE LOSSES IN THE HOMOGENIZED MODEL – PERFECT ABSORPTION

The losses are due to viscothermal effects which are dominant within the resonators, and we assume that they can be neglected in the air outside. Strictly speaking, losses could be accounted for by considering the whole set of equations (linearized Navier-Stokes equation with the equations of energy conservation, see *e.g.* [21]). More usually, it is done by considering complex values of the wavenumbers, distinguishing between the losses in the cavity and in the neck, namely

$$k_{c,n} = k \left(1 + \frac{1+i}{\sqrt{k}} \alpha_{c,n} \right), \quad (21)$$

with α_c, α_n defined by

$$\alpha_{c,n} = \sqrt{\frac{\nu}{c}} \left(1 + \frac{\gamma-1}{\sqrt{P_r}} \right) \frac{1}{h_{c,n}}, \quad (22)$$

with in the air $P_r = 0.7$ the Prandtl number, $\nu = 1.5 \cdot 10^{-5} \text{ m}^2 \cdot \text{s}^{-1}$ the kinematic viscosity, $c = 340 \text{ m} \cdot \text{s}^{-1}$ the sound speed and $\gamma = 1.4$ the heat capacity of air [14, 22], hence $\alpha_{c,n} = 3 \cdot 10^{-4} / h_{c,n} \text{ m}^{-1/2}$.

Results on R and A_c as a function of $kh \in (0, 1)$ are reported in Fig. 8 for $\theta = 40^\circ$. As expected, the effect of the losses is in general visible at the two resonances, by means of low $|R| < 1$ values and a decrease in A_c when compared to the lossless case in Fig. 7. However, the first resonance at $kh \simeq 0.15$ is weakly affected by the losses in the compact array ($|R|$ does not decrease significantly, and A_c is not peaked). In contrast, for the sparse array, almost perfect absorption $|R| = 0$ is obtained. In this case, the enhancement of the resonance produces higher absorption. It is worth noting that the tendency is inverse at the second resonance frequency $kh_c \simeq 0.6$, with a decrease in the absorption. This is known to result from a balance between the losses and the leakage.

FIG. 8: (a) Reflection coefficient $|R|$ and (b) maximum amplitude in the cavity A_c as a function of kh . Direct numerics (symbols) and homogenized solutions (plain lines). The incidence is $\theta = 40^\circ$ for a spacing $h = 3$ and 9 cm realizing perfect absorption at the resonance.

To inspect this balance, we use an approximate value of Z in (9) and from (17)

$$R \simeq \frac{k_r t_r - \frac{1}{h_c \mathcal{B}} - (i - \delta_v) \alpha_{RD} + i \alpha_{VD}}{k_r t_r - \frac{1}{h_c \mathcal{B}} + (i - \delta_v) \alpha_{RD} + i \alpha_{VD}}, \quad (23)$$

$$A_c \simeq \frac{2}{k_r t_r - \frac{1}{h_c \mathcal{B}} + (i - \delta_v) \alpha_{RD} + i \alpha_{VD}},$$

where

$$\alpha_{RD} = \frac{k_r}{k} \frac{t_r}{\cos \theta h \mathcal{B}}, \quad \alpha_{VD} = \delta_v k_r t_r, \quad (24)$$

where we have defined $k_c = k_r + ik_i$ and $\tan k_c d = t_r + it_i$, and the parameter $\delta_v = (k_i/k_r + t_i/t_r)$ which encapsulates the losses. In the lossless case, $\delta_v = 0$, we recover (18) and the resonance is simply given by $\varphi_c k h \tan k d = 1/\mathcal{B}$. In the lossy case, perfect absorption can be obtained at the critical coupling, when the losses iL balance the leakage $ik \cos \theta \left(\frac{1}{\varphi_c k_r t_r} - h\mathcal{B} \right)$ and in the present case, when this condition is compatible with that of $1 = kh \cos \theta \mathcal{B} L$. In order to fulfill these two conditions, we need two degrees of freedom which are provided by (k, h) , although it is not guaranteed that a solution can be found for any geometry of the resonators. We report $|R|$ computed numerically against (k, h) in Fig. 9 for the same geometry of the resonators as in Fig. 8 ($e = 0.6$ cm) and in Fig. 10 by enlarging $e = 2.4$ cm.

FIG. 9: Modulus of the reflection coefficient $|R|$ in the presence of losses. The geometry of the resonators is given and $|R|$ is computed against (k, h) revealing a perfect absorption $|R| = 0$ for $h = 9.165$ cm and $k = 0.191$ cm $^{-1}$. (b) same representation for $e = 2.4$. $h = 5.65$ cm, $k = 0.1261$ cm $^{-1}$

Finally, the sensitivity of the perfect absorption on h is illustrated in Figs. 10 where we report the wavefields for the same Helmholtz resonators arranged on an array with spacing $h = 9$ cm (realizing perfect absorption) and with a spacing $h = 3$ cm. To get a perfect absorption for a spacing $h = 3$ cm, we should use $e = 7$ cm (and for a spacing $h = 1$ cm, e about 15 cm).

V. CONCLUSION

An effective homogenized model for an array of Helmholtz resonators has been proposed. The model has been shown to accurately capture the scattering properties of the array, and provides a comprehensive picture of the acoustic pressure field inside the cavities. A simplified version of this model yields a new impedance condition which guarantees the same accuracy as the complete model. Among the various geometrical parameters of the array, the degree of freedom provided by the spacing is of particular interest since it does not affect the total thickness of the decorated wall. Moreover, we have shown that sparser arrays produce stronger resonances. This means

FIG. 10: Wavefields for an incident wave ($kh_c = 0.19$, $\theta = 40^\circ$) on an array of Helmholtz resonators ($d/h_c = 5$, $e/h_c = 0.6$, $h_n/h_c = 0.3$) and (a) $h/h_c = 9$ realizing perfect absorption, (b) $h/h_c = 3$ for comparison.

that the array spacing modifies the radiative damping while it does not influence the viscous damping, this latter being dictated by the geometry of a single resonator within the array. As such, it can be used to reach the critical coupling condition realizing perfect absorption.

A direct extension of the present study is the case of Helmholtz cavities open at their two sides, including asymmetrical termination as considered in [23]. Another, less straightforward, extension is the case of different Helmholtz resonators within a periodic cell, which should produce broadband absorption.

Appendix A: Simple procedure to get the coefficients $(\mathcal{B}, \mathcal{C})$

The problem 1 reads, with P periodic *w.r.t.* x ,

$$\begin{cases} \Delta P = 0, \\ \partial_n P|_\Gamma = 0 \\ \lim_{y \rightarrow +\infty} \nabla P = \mathbf{e}_y, \quad \lim_{y \rightarrow -\infty} \nabla P = \frac{\mathbf{e}_y}{h_c}, \end{cases} \quad (\text{A1})$$

P can be written for the problem 1,

$$P(\mathbf{y}) = \begin{cases} \frac{y}{h_c} + \sum_{n=0}^{N^c} R_n e^{a_n^c(y+e)} P_n^c(x), \\ \frac{y}{h_n} + \sum_{n=0}^{N^n} A_n e^{a_n^y} P_n^n(x) + \sum_{n=1}^{N^n} B_n e^{-a_n^y(y+e)} P_n^n(x), \\ \frac{y}{h} + \sum_{n=-N, n \neq 0}^N T_n e^{-|b_n|y} P_n(x), \end{cases} \quad (A2)$$

with $a_n^{c,n} = n\pi/h_{c,n}$, $b_n = 2n\pi/h$, and

$$P_n(x) = e^{ib_n x}, \quad P_n^{c,n}(x) = \sqrt{\frac{2 - \delta_{n0}}{h_{c,n}}} \cos\left(a_n^{c,n} x + \frac{n\pi}{2}\right), \quad (A3)$$

the transverse functions (forming a basis) adapted to solutions being respectively h - periodic and the transverse functions adapted to solutions with zero derivatives at $x = \pm h_{c,n}/2$. Mode matching techniques are then used at $y = -e$ and $y = 0$ (we ask to P to match on average their values and their first derivatives, accounting for the boundary conditions at $y = -e, 0$ and $|x| > h_{c,n}/2$). We get a matrix system for the vectors $\mathbf{R}$, $\mathbf{A}$, $\mathbf{B}$ and $\mathbf{T}$ of the form

$$\begin{pmatrix} C_1 & 0 & -e^{-A^n e} & -1 & 0 \\ A^c & 0 & -A^n e^{-A^n e} D_1 & A^n D_1 & 0 \\ 0 & C_2 & -1 & -e^{-A^n e} & 0 \\ 0 & |B| & -A^n D_2 & -A^n e^{-A^n e} D_2 & 0 \\ c_1 & 0 & 0 & 0 & -1 \\ 0 & c_2 & 0 & 0 & -1 \end{pmatrix} \begin{pmatrix} \mathbf{R} \\ \mathbf{T} \\ \mathbf{A} \\ \mathbf{B} \\ A_0 \end{pmatrix} = \begin{pmatrix} Q_C \\ S_1 \\ 0 \\ S_2 \\ s \\ 0 \end{pmatrix}, \quad (A4)$$

with $A^{c,n} = \text{diag}(a_n^{c,n})$, $B = \text{diag}(|b_n|)$, and

$$C_{1,mn} = \int_{-h_c/2}^{h_c/2} dx P_m^n(x) P_n^c(x),$$

$$C_{2,mn} = \int_{-h_c/2}^{h_c/2} dx P_m^n(x) P_n(x).$$

Finally, $D_i = {}^t C_i^*$, $i = 1, 2$ are the transposed conjugated matrices and $c_{i,n} = C_{i,1n}$. The source terms read

$$\begin{cases} S_{1,m} = D_{1,m1}/\sqrt{h_n} - \delta_{m0}/\sqrt{h_c}, \\ S_{2,m} = -D_{2,m1}/\sqrt{h_n}, s = (e/h_c - e/h_n)\sqrt{h_n}. \end{cases} \quad (A5)$$

The system invertible and can be solved to find $\mathbf{R}$, $\mathbf{T}$. Finally, $\mathcal{B}$ is given by

$$\mathcal{B} = -\frac{R_0}{\sqrt{h_c}}. \quad (A6)$$

The problem 2 reads, with $(P - x)$ periodic *w.r.t.* x ,

$$\begin{cases} \Delta P = 0, \\ \partial_n P|_{\Gamma} = 0 \\ \lim_{y \rightarrow +\infty} \nabla P = \mathbf{e}_x, \quad \lim_{y \rightarrow -\infty} \nabla P = \mathbf{0}, \end{cases} \quad (A7)$$

P can be written

$$y < -e, \quad \begin{cases} \sum_{n=1}^{N^c} R_n e^{a_n^c(y+e)} P_n^c(x), \\ \sum_{n=1}^{N^n} (A_n e^{a_n^y} P_n^n(x) + B_n e^{-a_n^y(y+e)}) P_n^n(x), \end{cases} \quad y < -e, \\ 0 < y, \quad \begin{cases} x + \sum_{n=-N, n \neq 0}^N T_n e^{-|b_n|y} P_n(x), \end{cases} \quad 0 < y, \quad (A8)$$

where n only takes odd values (P being odd *w.r.t.* x). The mode matching procedure is the same as in the problem 1, and we get

$$\begin{pmatrix} C_1 & 0 & -e^{-A^n e} & -1 \\ A^c & 0 & -A^n e^{-A^n e} D_1 & A^n D_1 \\ 0 & C_2 & -1 & -e^{-A^n e} \\ 0 & |B| & -A^n D_2 & -A^n e^{-A^n e} D_2 \\ c_1 & 0 & 0 & 0 \\ 0 & c_2 & 0 & 0 \end{pmatrix} \begin{pmatrix} \mathbf{R} \\ \mathbf{T} \\ \mathbf{A} \\ \mathbf{B} \end{pmatrix} = \begin{pmatrix} \mathbf{0} \\ \mathbf{0} \\ \mathbf{S}_3 \\ \mathbf{0} \end{pmatrix}, \quad (A9)$$

with $S_{3,m} = 2\sqrt{2/h_n}/(a_m^n)^2$, and $\mathcal{C}$ is given by

$$\begin{pmatrix} Q_C \\ S_1 \\ 0 \\ S_2 \\ s \\ 0 \end{pmatrix} = -2\sqrt{\frac{2}{h_c}} \sum \frac{R_n}{a_n^c} - 2\sqrt{\frac{2}{h_n}} \sum (1 - e^{-a_n^y e}) \frac{(A_n + B_n)}{a_n^n}. \quad (A10)$$

Appendix B: From the complete model to an impedance model

We shall now simplify the complete model to get such condition and to that aim, we consider the general solution

$$p(x, y) = A(x) \cos k_c(y + D), \quad -D < y < -e, \quad (B1)$$

satisfying the wave equation in (6) and the Neumann boundary condition (5) at $y = -D$. Next, applying (7), we get that

$$\begin{cases} p^+ = \frac{h\mathcal{B}}{2} v^+ + \hat{A} \left[1 - \frac{h\mathcal{B}}{2} \varphi_c k_c \tan k_c d \right], \\ \frac{e\varphi_n}{2} k_n^2 p^+ = -v^+ + \hat{A} \left[\varphi_c k_c \tan k_c d + \frac{e\varphi_n}{2} k_n^2 \right] \\ -\frac{h\mathcal{C}}{2} \frac{d^2}{dx^2} (\hat{A} + p^+), \end{cases} \quad (B2)$$

where $\hat{A} = p^-$ hence $\hat{A} = A(x) \cos k_c d$ from (B1) and $v^- = -\hat{A} \varphi_c k_c \tan k_c d$. Obviously, the obtention of an impedance condition requires the variations of $(\hat{A} + p^+)$ on x to be neglected. Doing so, we get $p^+ = -Zv^+$ with

$$Z = \frac{1 - h\mathcal{B}\varphi_c k_c \tan k_c d - \frac{h\mathcal{B}}{4} e\varphi_n k_n^2}{\varphi_c k_c \tan k_c d + e\varphi_n k_n^2 (1 - \frac{h\mathcal{B}}{4} \varphi_c k_c \tan k_c d)}. \quad (B3)$$

Appendix C: Derivation of the classical impedance condition

A classical derivation of the impedance condition is done using a monomodal approximation in the cavity and in the neck, whence all the fields are dependent on y only. In the cavity, the solution is then simply $p(y) = A \cos(k_c(y + D))$ with $D = d + e$ ensuring the Neumann boundary condition at $y = -D$ to be satisfied. With $v(y) = p'(y)$, it follows that

$$\frac{v(-e^-)}{p(-e^-)} = -k_c \tan k_c d. \quad (C1)$$

Next, the continuities of the pressure $p(-e^-) = p(-e^+)$ and of the flow rate $\varphi_c v(-e^-) = \varphi_n v(-e^+)$ yield

$$Y_e \equiv \frac{v(-e^+)}{p(-e^+)} = -\frac{\varphi_c}{\varphi_n} k_c \tan k_c d. \quad (C2)$$

In the neck, the propagation is written $p(y) = a \cos(k_n(y + e)) + b \sin(k_n(y + e))$ (whence $a = p(-e^+)$

and $b = v(-e^+)/k_n$). It follows that

$$\frac{v(0^-)}{p(0^-)} = -\frac{k_n \tan k_n e - Y_e}{1 + Y_e \tan k_n e/k_n}. \quad (C3)$$

It is now sufficient to apply again the continuity of the pressure and of the flow rate ($\varphi_n v(0^-) = v(0^+)$) to get

$$\frac{v(0^+)}{p(0^+)} = -\varphi_n \frac{k_n \tan k_n e + \frac{\varphi_c}{\varphi_n} k_c \tan k_c d}{1 - \frac{k_c \varphi_c}{k_n \varphi_n} \tan k_c d \tan k_n e}, \quad (C4)$$

which gives $Z = -p(0)/v(0)$ of the form

$$Z = \frac{1 - \frac{k_c \varphi_c}{k_n \varphi_n} \tan k_c d \tan k_n e_{\text{eff}}}{\varphi_c k_c \tan k_c d + \varphi_n k_n \tan k_n e_{\text{eff}}} \quad (C5)$$

where e has been replaced by e_{eff} .
