Relationships between Work-related Characteristics, Needs Satisfaction, Motivation and
Mental Health in Midwifery Students

Ferrand, C., Courtois, R., Martinent, G., Rivière, M.*, & Rusch, E.

Abstract

The present study examined the relationships between work-related characteristics in internships, psychological needs satisfaction, motivation and mental health using a partial least squares path modeling. Midwifery students ($N = 214$; $M_{age} = 22.8$ years) from three French schools completed different questionnaires online. Results showed (1) the importance of work resources (work control and social support) as protective factors of psychological needs satisfaction; and (2) the role of competence need satisfaction through motivation in the relationships between work resources and mental health. Midwifery schools should pay more attention to these two results, and take them into account in midwifery students' training.

Keywords: self-determination, midwifery students, psychological needs satisfaction, motivation, mental health

Relationships between Work-related Characteristics, Needs Satisfaction, Motivation and Mental Health in Midwifery Students

In midwifery studies, internships in hospitals are a vital component of the student experience. Some studies have pointed out that internships were often recognized as work-stressful places (e.g., Carolan-Olah & Gruger, 2014), and too much work-related stress might have negative effects on students' learning and success (e.g., Sarikaya, Civaner, & Kalaca, 2006), and can cause mental health problems (e.g., Gammon & Morgan-Samuel, 2005). Indeed, learning occurs though interaction in the environment and the conflicting demands of being both a learner and an emerging professional can be particularly a difficult experience physically and stressful, for students when the environment is not conducive to learning (Flenghi, 2012; Pearcey & Elliott, 2004). Thus, it seems necessary to gain insight into the psychological processes underlying the relationships between work-related characteristics and mental health. Few studies have focused on the interplay between work-related characteristics in internships, psychological needs satisfaction, motivation and mental health. Consequently, the present study examined these relationships using a partial least squares path modeling approach (PLS-PM; Sanchez, 2013).

One theory on which we can rely for this study is the self-determination theory (SDT, Deci & Ryan, 1985). SDT has shown the existence of three innate basic needs: autonomy need (the need to experience volition, freedom in one's actions and choices), competence need (the need to feel competent in doing optimally challenging activities and in mastering one's environment) and relatedness need (the need to have a sense of belonging and mutual respect) (e.g., Li, Wang, Pyun, & Kee, 2013, p.327). The satisfaction of these needs plays a crucial part in the process of maintaining autonomous forms of motivation in individuals. Indeed, the distinction between autonomous forms of motivation (intrinsic motivation, identified and integrated regulations), controlled regulations (introjected, external regulations)

1 and amotivation allows us to understand that the extent to which needs are satisfied will
2 determine the types of motivation endorsed by individuals and their effects on mental health
3 (Ryan & Deci, 2002). High levels of needs satisfaction would be positively related to
4 autonomous regulations, and negatively associated to controlled regulations and amotivation.
5 Moreover, SDT has shown that greater mental health was associated with needs satisfaction
6 and autonomous regulations (e.g., Ryan & Deci, 2002), and considers mental health as a state
7 of complete physical, mental and social well-being and not merely the absence of disease. For
8 these reasons two indexes such as quality of life and psychological distress will be taken into
9 account to measure mental health.

10 The Demand-Control-Support model (DCS, Karasek & Theorell, 1990) is one of the
11 most used models of stress in the workplace and indicated that individuals who were exposed
12 to high levels of psychological work demands and low work control and social support levels
13 were likely to be subjected to a lot of stress. In contrast, the work resources (e.g., work control
14 and social support), when they are high, can reduce psychological work demands and
15 contribute to the good mental health of individuals. SDT has shown some positive
16 relationships between work resources and psychological needs. Work control was positively
17 related to autonomy and competence needs, and social support was positively linked to
18 relatedness need (e.g., Van den Broeck, Vanteenkiste, De Witte, Soenens, & Lens, 2010) or to
19 relatedness and autonomy needs (e.g., Ryan & Solby, 1996).

20 A model was tested in which psychological needs act as mediators indirectly through
21 motivation of the relationship between psychological work demands, work resources (i.e.,
22 work control and social support) and mental health. It was predicted (1) a negative
23 relationship between psychological work demands and psychological needs satisfaction; (2) a
24 positive relationship between work resources and psychological needs satisfaction; (3) that
25 psychological needs satisfaction would be associated positively with autonomous motivation

and negatively with controlled regulations and amotivation ; and (4) that autonomous motivation would be associated positively with quality of life and controlled regulations and amotivation would be associated positively with psychological distress.

Methods

Participants

214 French midwifery students ($M_{age} = 22.8$ years, age range: 19-41 years) were recruited from three midwifery schools in the regions “Centre” and ‘Pays de la Loire” to participate in this study. Participants represented 68.6% of students of the three schools (n = 312). Table 1 shows the students’ characteristics.

Measures

Questionnaires. Participants will be asked to complete several validated questionnaires relating to (1) psychological needs satisfaction (three different questionnaires assessing autonomy need satisfaction [5 items; Standage, Duda, & Ntoumanis, 2003]; competence need satisfaction (IMI; 5 items, Mc Auley, Duncan, & Tammen, 1989) and relatedness need satisfaction (6 items, NRS-10; Richer & Vallerand, 1998)); (2) behavioural regulations [24 items with six 4-item subscales representing the motivational regulations; Van Hove, Ramanoel, Heuze, & Sarrazin, 2010)] (3) mental health [26 items; the WHOQOL-Bref, Leplege, Reveillere, Ecosse, Caria, & Riviere (2000) and the General Health Questionnaire-12 items, Lesage, Martens-Resende, Deschamps,& Berjot (2011)]; and (4) the Demand-Control-Support model [DCS, 26-item with psychological work demands (9 items), decisional latitude (9 items) and social support at work (8 items), Niedhammer, Chastaing, Gendrey, & David (2006)]. Cronbach's alphas for psychological needs satisfaction range between .70 and .87, for behavioural regulations they range between .67 and .95, for Whoquol-Bref and psychological distress they are .85 and .84, and for DCS they range between .70 and .80, respectively, showing acceptable internal consistency (Nunnally, 1978)

Procedure

Permission to conduct this study was granted by the University of Human Research Ethics. Written informed consent was obtained from students. Participation was voluntary, and students responded individually and anonymously to an online set of questionnaires (approximately 35 minutes).

Data analysis

PLS-PM was used. To retain a reasonable number of manifest variables in the model, the different constructs were measured by three or four aggregates of items (e.g., Little, Cunningham, Shahar, & Widaman, 2002). See Table 3.

Results

Descriptive statistics and correlations for all study variables are shown in Table 2.

Results from the PLS-PM measurement model (outer model) provided evidence for the reliability and validity of all the constructs. Loadings, ρ values, AVE values, and first and second eigenvalues are reported in Table 3.

Results from the PLS-PM structural model (inner model) are presented in Figure 1.

Discussion

Results showed that work control and social support were positively related to the three needs satisfaction. Individuals who are surrounded by resourceful work characteristics would be more likely to experience a general feeling of psychological freedom (i.e., autonomy), interpersonal connectedness (i.e., relatedness), and effectiveness (i.e., competence). So, our findings highlight the importance of these factors for improving psychological needs satisfaction. Contrary to our expectation, psychological work demands were unrelated to the three needs satisfaction. This result suggests that the level of demands has not functional significance in terms of needs satisfaction (Deci, Ryan, Gagne, Leone, Usunov, & Kornazheva (2001).

Results also showed that only competence need satisfaction contributed positively and significantly to the prediction of autonomous motivation and negatively and significantly to controlled regulations and amotivation. Autonomous motivation was a significant positive predictor of quality of life, and controlled regulations and amotivation were significant positive predictors of psychological distress. The need for competence leads to the perception of mastery, achievement and control, and allows individuals to efficiently adapt to complex and changing environments (Van den Broeck et al., 2010). Findings highlight the link between competence need satisfaction and motivational mechanisms leading to a good perceived mental health (e.g., low psychological distress and high quality of life).

Some limitations of the present study should be considered. First, all measures were self-reported. Caution with regard to over-interpretation should be considered. Second, participants are in different levels of training and internships (1st through 4th year). Warr (1990) suggested that for testing the relationships between work-related characteristics and outcomes, it was important to include a large range of work increasing the variability in work-related characteristics. Lastly, midwifery student volunteers are a geographically-select sample, and expanding the study into a broader sample of midwifery students is required.

Conclusion and implications for practice

Our results underscore the positive predictive relationships of not only social support, but also work control characteristics on needs satisfaction. If work resources are recognized as stimulating personal growth, development and learning (Schaufeli & Bakker, 2004), our findings highlight the importance in training of boosting psychological needs satisfaction to improve the students' optimal functioning and work-related well-being. The findings also provided evidence that competence need satisfaction though motivation played a crucial role in the relationships between work resources and mental health. This suggests that participants are very focused on skills acquisition to better prepare themselves for practice and gain

confidence (e.g., McIntosh, Fraser, Stephen, & Avis, 2012), are motivated, and it seems possible because the work-related environment is perceived as sufficiently supportive. The overall results suggest the importance of interpersonal relationships and the focal role of clinical preceptor in training (Maxwell, Black, & Baillie, 2015). Feedback in general, and debriefing after acute situations in particular, are important in enhancing their learning. Midwifery schools should continue to develop appropriate strategies such as a personalized follow up or the use of preceptorship programs (Licqurish & Seibold, 2008) to better accompany the transition between the student status and that of professional.
