Abstract. We present a second order scheme for the barotropic and full Euler equations. The scheme works on staggered grids, with numerical unknowns stored at dual locations, while the numerical fluxes are derived in the spirit of kinetic schemes. We identify stability conditions ensuring the positivity of the discrete density and energy. We illustrate the ability of the scheme to capture the structure of complex flows with 1D and 2D simulations on MAC grids.

1 Introduction

This work is concerned with the development of numerical schemes on staggered grids for the Euler equations. Using staggered grids is non standard for the discretization of hyperbolic system (see e.g. [11,19,26,36,50]), since, when stored on a collocated grid, the unknowns of the system are usually gathered in a single vector-valued unknown allowing to identify the wave structure of the system in order to build upwinding techniques. The motivation of the use of staggered grids comes from the attempt to have an unified approach with an incompressible code, see e.g. [25,28,51,53–55]. This is particularly relevant when dealing with low-Mach simulations since letting the Mach number go to 0 enforces incompressibility and collocated approaches might lead to numerical difficulties in this regime, and to the development of spurious instabilities due to an “odd-even decoupling”, see [20,21,57] and the references therein. This is also of interest in multifluid flows simulations that involve additional solenoidal constraints on a velocity field, see e.g. [6,16,17,47]: coupled with a projection approach, the staggered method makes the discretization of the mass conservation equations for all the species interacting in the mixture and the definition of the pressure field (the Lagrange multiplier associated to the solenoidal constraint) compatible.

We first deal with the barotropic Euler system

\[ \begin{align*}
\partial_t \rho + \nabla \cdot (\rho \mathbf{u}) &= 0, \\
\partial_t (\rho \mathbf{u}) + \nabla \cdot (\rho \mathbf{u} \otimes \mathbf{u}) + \nabla (p(\rho)) &= 0.
\end{align*} \]  

(1.1)

This model describes the evolution of a compressible fluid (in the absence of external forces). The unknowns \( \rho \) and \( \mathbf{u} \) stand respectively for the local density and velocity field of the fluid. They depend on the time and space variables, \( t \geq 0 \) and \( x \in \mathbb{R}^N \). The model assumes that the pressure \( p \) depends on the density \( \rho \) only. Here and below, we suppose that the pressure law \( \rho \mapsto p(\rho) \) belongs to \( \mathcal{C}^2([0,\infty)) \) and satisfies

\[ p(\rho) > 0, \quad p'(\rho) > 0, \quad p''(\rho) \geq 0, \quad \forall \rho > 0. \]

For instance, these properties hold for the classical power-law \( p(\rho) = \lambda \rho^\gamma \) with \( \lambda > 0 \) and \( \gamma > 1 \). We refer the reader to the classical treatises [11,19,26,36,50] for a thorough introduction to these equations and for a description of the numerical issues. Our aim is here to extend at the second order and to higher dimension the scheme introduced in [5]. This scheme is characterized by the following two main features:

- first of all, as said previously, it works on staggered grids, meaning that densities and velocities are stored on different grid points,
- second of all, the fluxes are defined with a flavor of kinetic schemes [18,22,23,32,44,45].
Consequently, the scheme differs in many aspects from standard approaches, for which we refer the reader e. g. to [11,50]. In particular, due to the staggered discretization, the system is not treated “as a whole”, but each equation are updated successively, which makes the numerical analysis different, see e.g. [4,24,28,30,49]. Next, the definition of the fluxes involves the characteristic speeds of the system, but, despite the “kinetic” motivation, their evaluation do not require to compute complicated integrals. They are defined by simple formula and they do not require additional computational cost. The scheme can be shown to preserve the positivity of the density and the entropy dissipation property under a suitable CFL condition [5], it is thus consistent with the Euler system [4].

Next, we address the full Euler model

$$\partial_t \begin{pmatrix} \rho \\ \rho u \\ \rho E \end{pmatrix} + \nabla \cdot \begin{pmatrix} \rho u \otimes u + p \mathbb{I} \\ \rho E u + p u \end{pmatrix} = 0. \tag{1.2}$$

As previously, the unknowns depend on the time and space variables \((t,x) \in [0,\infty) \times \mathbb{R}^N\); \(\rho, u, E\) and \(p\) stand for the mass density, the velocity, the total energy and the pressure respectively. The pressure is now related to the independent unknowns \((\rho, u, E)\) through an equation of state; in what follows the internal energy \(e\) and the pressure \(p\) are defined by setting

$$E = \frac{\|u\|^2}{2} + e, \quad p = (\gamma - 1)\rho e, \tag{1.3}$$

where \(\gamma > 1\) is the adiabatic exponent. The staggered approach induces a new difficulty since in the energy equation, the total energy \(E\) involves quantities – the velocity and the internal energy – which are defined on different grids. To cope with this issue, it is tempting to work with the internal energy equation, namely

$$\partial_t (\rho e) + \nabla \cdot (\rho e u) = -p \nabla \cdot u, \tag{1.4}$$

instead of the evolution equation for \(\rho E\), since discrete densities, pressures, and internal energies are naturally stored at the same locations. Unfortunately, as it is well-known, this non conservative formulation is not equivalent to (1.2) when the solution presents discontinuities and schemes that use naively this formulation produce wrong solutions [31]. We refer the reader to [1,33,34] for a thorough description of numerical difficulties and attempts to design a scheme that use the primitive variables \((\rho, u, p)\) and non conservative formulations. In what follows, we shall adapt the approach discussed in [24,28,30] by plugging in the discrete version of (1.4) correction terms that account for the kinetic energy balance. The scheme introduced in [28,30] can be shown: a) to be consistent with (a weak form of) the total energy equation as the space step \(\delta x\) goes to zero and b) to conserve the global discrete total energy. Even if these properties ensures that the scheme properly compute the correct weak solution (in particular, with shocks satisfying the Rankine-Hugoniot conditions), the practitioner can be disappointed by the lack of a form of local conservation for a total energy. We address this issue in this article by defining averaged total energies that satisfy conservation relations.

Thus, the purpose of the present work can be summarized as follows:

• to adapt the scheme of [5] for dealing with the full Euler system (1.2),
• to establish local conservation relations satisfied by averaged total energies,
• to include reconstructed quantities in the definition of the fluxes, in the spirit of MUSCL schemes [52], in order to improve the accuracy of the scheme,
• to explain how the schemes can be extended to higher dimensions. The staggered framework naturally leads to a MAC-like discretization, in the spirit of the pioneering work [27] for incompressible flows,

• to analyse the properties of the schemes. In particular, we will discuss stability conditions so that the numerical densities and internal energies (for full Euler system) remain positive.

This work is organized as follows. In Section 2, we start by briefly describing the scheme designed in [5] for the barotropic Euler system and by recalling its main features. The remainder of this section is then devoted to the extension of the scheme to deal with the full Euler system in 1D. Finally, we exhibit the stability conditions that ensure the positivity of the density and internal energy and we define averaged total energies that satisfy a local conservation equation.

Next, we explain in Section 3 the adaptation of the MUSCL procedure to the staggered schemes and justify that the construction reaches formally the second order accuracy. In Section 4, we briefly explain how to extend the 1D scheme to higher dimensions, when working with Cartesian grids. The case of general meshes will be addressed elsewhere, see [39, Chapter 4]. Section 5 is devoted to numerical validations for both barotropic and full Euler systems. We check numerically the gain of accuracy on explicit solutions and on 1D Riemann problems. Then we address 2D cases, like the simulation of falling columns by the Shallow Water system, as proposed in [2], and the forward facing step inspired from [56].

2 First order numerical schemes and their main properties

2.1 Staggered grids and notation

We focus in this section on the one-dimensional case where \( x \) lies in the slab \([0,L] \subset \mathbb{R}\). To define the discrete unknowns, we proceed as follows, see Fig. 1:

• we introduce a set of \( J+1 \) points \( x_1 = 0 < x_2 < \ldots < x_J < x_{J+1} = L \) in the computational domain; we denote by \( C_{j+\frac{1}{2}} = [x_j, x_{j+1}] \), \( j \in [1,J] \), the cells defined by these points;

• we denote by \( x_{j+\frac{1}{2}} = (x_j + x_{j+1})/2 \), \( j \in [1,J] \), the centers of the cells; these points define the dual cells \( C_j = [x_j - \frac{1}{2}, x_j + \frac{1}{2}] \), \( j \in [2,J] \);

• we set the following notation for the mesh-sizes

\[
\delta x_{j+\frac{1}{2}} = x_{j+1} - x_j, \quad j \in [1,J], \quad \text{and} \quad \delta x_j = \frac{\delta x_{j+\frac{1}{2}} + \delta x_{j-\frac{1}{2}}}{2}, \quad j \in [2,J],
\]

(with the specific definition for the end-cells: \( \delta x_1 = \frac{1}{2} \delta x_{\frac{1}{2}} \) and \( \delta x_{J+1} = \frac{1}{2} \delta x_{J+\frac{1}{2}} \)).

Figure 1: Staggered grid in dimension one.
We have in mind the derivation of Finite Volume schemes where the discrete densities \( \rho_{j + \frac{1}{2}} \) (resp. internal energies \( e_{j + \frac{1}{2}} \)) are thought of as approximation of the density \( \rho \) (resp. internal energy \( e \)) on the cells \( C_{j + \frac{1}{2}} \) whereas the discrete velocities \( u_j \) are thought of as approximation of the velocity \( u \) on the cells \( C_j \).

The time discretization is explicit and we use the convention that, with \( q \) the evaluation of a certain quantity at time \( t \), \( \bar{q} \) stands for its update at time \( t + \delta t \).

### 2.2 Discretization of the barotropic Euler system

The scheme for barotropic Euler equations has the general form

\[
\frac{\bar{p}_{j + \frac{1}{2}} - p_{j + \frac{1}{2}}}{\delta t} + \frac{\bar{F}_{j + \frac{1}{2}} - F_{j + \frac{1}{2}}}{\delta x_{j + \frac{1}{2}}} = 0, \quad \forall j \in [1, J].
\]  

(2.1)

\[
\frac{\bar{p}_{j} - p_{j} u_{j}}{\delta t} + \frac{\bar{G}_{j + \frac{1}{2}} - G_{j + \frac{1}{2}}}{\delta x_{j}} + \frac{\Pi_{j + \frac{1}{2}} - \Pi_{j - \frac{1}{2}}}{\delta x_{j}} = 0, \quad \forall j \in [2, J].
\]  

(2.2)

Equation (2.1) is the discrete version of the mass balance equation and equation (2.2) is the discrete version of the momentum balance equation. Of course, the scheme has to be completed by the definition of mass fluxes \( F_{j} \), momentum fluxes \( G_{j + \frac{1}{2}} + \Pi_{j + \frac{1}{2}} \) (with \( \Pi_{j + \frac{1}{2}} \) an approximation of the pressure) and by initial and boundary conditions. The discrete momentum balance involves quantities \( \rho_{j} \) which stand for the approximations of \( \rho \) at the internal edges of the primal mesh and are obtained as averages of quantities \( \rho_{j - \frac{1}{2}} \) and \( \rho_{j + \frac{1}{2}} \) as follows:

\[
\rho_{j} = \frac{\delta x_{j + \frac{1}{2}} p_{j + \frac{1}{2}} + \delta x_{j - \frac{1}{2}} p_{j - \frac{1}{2}}}{2 \delta x_{j}}, \quad \forall j \in [2, J].
\]  

(2.3)

In contrast to the collocated approach (with the noticeable exception of AUSM schemes [37,38]), a discretization of each physical variables, \( \rho \) and \( u \) separately, is natural on a staggered grid. In particular, the mass flux \( F_{j} \) at the interface \( x_{j} \) can use directly the material velocity \( u_{j} \). For instance, it looks tempting to define the flux \( F_{j} \) based on the UpWinding principles according to the sign of \( u_{j} \), see [30], but this approach does not use the hyperbolic properties of the system (1.1) and requires extra-diffusion to reduce spurious oscillations that might appear, see [5, Appendix B]. Instead, the flux designed in [5,6] makes full use of the characteristic speeds of the system (1.1), namely

\[
\lambda_{\pm}(c,u) = u \pm c,
\]

where \( c \) stands for the sound speed.

In the barotropic case, the sound speed depends only on \( \rho \), that is \( c = c_b(\rho) \) with

\[
c_b(\rho) = \sqrt{\rho'(\rho)}.
\]

The numerical mass fluxes are given by the following formula

\[
F_{j} = F_{j}^{+} + F_{j}^{-}, \quad \forall j \in [1, J + 1],
\]

where

\[
F_{j}^{+} = F^{+}(\rho_{j - \frac{1}{2}}, c_{j}, u_{j}) \quad \text{and} \quad F_{j}^{-} = F^{-}(\rho_{j + \frac{1}{2}}, c_{j}, u_{j}), \quad \forall j \in [2, J],
\]  

(2.4)
with \( c_j = c_b(\rho_j) \). The definition of \( F^+_1 \) and \( F^+_j \) depends on the prescribed boundary conditions. The flux functions \( F^\pm \) are defined as follows

\[
F^+(\rho, c, u) = \begin{cases} 
0 & \text{if } u \leq -c, \\
\frac{\rho}{4c} (u + c)^2 & \text{if } |u| \leq c, \\
\rho u & \text{if } u \geq c,
\end{cases}
\]  
(2.5)

and

\[
F^-(\rho, c, u) = \begin{cases} 
\rho u & \text{if } u \leq -c, \\
-\frac{\rho}{4c} (u - c)^2 & \text{if } |u| \leq c, \\
0 & \text{if } u \geq c.
\end{cases}
\]  
(2.6)

We do not explain in this article the derivation of these expressions which is related to kinetic schemes, but we refer the interested reader to [5, 6] where the complete derivation is provided.

We note that a symmetry property holds

\[
F^-(\rho, c, u) = -F^+(\rho, c, -u),
\]

and it is clear that the flux–consistency condition is fulfilled

\[
F^+(\rho, c, u) + F^-(\rho, c, u) = \rho u. \quad (2.7)
\]

It is worth having in mind Fig. 2, which clarifies the correction with respect to the mere UpWind flux based on the sign of the material velocity. As explained in [5], it induces some numerical diffusion which prevents the formation of oscillations in the vicinity of small material velocities.

![Figure 2: Comparison of the flux (2.5)–(2.6) and the UpWind flux for a fixed \( \rho \).](image-url)

For the momentum flux, the pressure gradient at \( x_{j+\frac{1}{2}} \) is naturally centered by using the densities in the neighboring cells with

\[
\Pi_{j+\frac{1}{2}} = p(\rho_{j+\frac{1}{2}}),
\]  
(2.8)

while the convection flux is written by applying the UpWinding principle, based on the “sign” of the mass fluxes \( F_j \) and \( F_{j+1} \), to the velocity field. We arrive at the following definition

\[
G_{j+\frac{1}{2}} = u_j F^+_{j+\frac{1}{2}} + u_{j+1} F^-_{j+\frac{1}{2}},
\]
where the quantities $F_{j+{1\over 2}}^\pm$ are expressed as mean values of $F_j^\pm$, $F_{j+1}^\pm$:
\[
F_{j+{1\over 2}}^\pm = \frac{F_j^\pm + F_{j+1}^\pm}{2}.
\] (2.9)

It is remarkable that a conservation relation holds with the dual quantities $\rho_j$ and $F_{j+{1\over 2}}^\pm$:
\[
\rho_j - \rho_j + \frac{\delta t}{\delta x_j} (F_{j+{1\over 2}} - F_{j-{1\over 2}}) = 0
\] (2.10)

where, of course, $F_{j+{1\over 2}} = F_{j+1}^+ + F_{j+1}^-$. Due to (2.7), it is clear that the momentum flux is also consistent.

The scheme has the following properties and abilities, at least in this simple 1D framework:
- stability analysis [5]: up to a (quite standard) stability condition on the numerical parameters, the scheme preserves the positivity of the density, and it makes the total energy of the system decay,
- consistency analysis [4]: the scheme satisfies a Lax-Wendroff type theorem,
- simulations: the scheme has the advantage of algorithmic simplicity (it does not require to solve Riemann problems and the definition of the flux (2.5)-(2.6) is fully explicit; despite its “kinetic” flavor, it does not require an additional integration procedure...), it performs well on the standard test cases of Riemann problems and it works for very general pressure laws, like with close-packing pressures, see [5,6].

We propose in the next section an extension of this scheme to the discretization of the full Euler system.

2.3 Discretization of the full Euler system

The discrete mass and momentum balance equations have been already derived in the previous section. We use here the same definitions except for the sound speed and the pressure. Indeed, as for the barotropic Euler system, the smallest and largest characteristic speeds of the full Euler system are $\lambda_{\pm}(c,u) = u \pm c$ (the third one being $u$) where $c$ is the sound speed. The sound speed now depends only on the internal energy, that is $c_c = c_f(\epsilon)$ with
\[
c_f(\epsilon) = \sqrt{(\gamma - 1)\gamma \epsilon}.
\]

Hence, it leads us to write
\[
c_j = c_f(\epsilon_j) \quad \text{with} \quad \epsilon_j = \frac{\epsilon_{j-{1\over 2}} + \epsilon_{j+{1\over 2}}}{2},
\]
in the definition of the mass fluxes (2.4). Moreover, in the full Euler system, the pressure is no longer defined as a function of the density only but instead using the state law (1.3), so that we set:
\[
\Pi_{j+{1\over 2}} = (\gamma - 1)\rho_j^{1\over 2} \epsilon_j^{1\over 2},
\]

instead of (2.8).

We now turn to the discrete version of the internal energy equation
\[
\frac{\overline{\rho}_j + \overline{\rho}_{j+{1\over 2}}} - \rho_j + \rho_j^{1\over 2} \epsilon_j^{1\over 2} \delta t \frac{\delta (\epsilon_j^{1\over 2})}{\delta x_j + {1\over 2}} + \epsilon_{j+1} - \epsilon_j + \Pi_{j+{1\over 2}} \delta x_j + {1\over 2} = S_{j+{1\over 2}}.
\] (2.11)
The left hand side corresponds to the discretization of (1.4), where the internal energy flux $E_j$ is given by

$$E_j = e_j - \frac{1}{2} F^+_j + e_{j+\frac{1}{2}} F^-_j. \tag{2.12}$$

This formula still corresponds to the UpWinding principle associated to the transport of $\rho e$ with velocity $u$, according to the definition of the mass fluxes. Note that the discretization of the non conservative term $p \partial_x u$ uses the velocity field $\bar{u}$, just updated in the previous step. Following [28], the right hand side $S_{j+\frac{1}{2}}$ is designed to account for the remainder term that appears in the discrete kinetic energy balance; it does not vanish when $\delta x$ goes to zero, precisely because it is intended to capture the correct behavior at discontinuities. To be more specific, the kinetic energy balance is obtained by multiplying (2.2) by $u_j$. We find, see [5,28]:

$$\frac{1}{2} \rho_j u_j^2 - \rho_j u_j^2 \delta t \frac{K_{j+\frac{1}{2}} - K_{j-\frac{1}{2}}}{\delta x_j} + \frac{\Pi_{j+\frac{1}{2}} - \Pi_{j-\frac{1}{2}}}{\delta x_j} \pi_j = - R_j,$$

where the kinetic energy flux is given by

$$K_{j+\frac{1}{2}} = \frac{u_{j+1}^2}{2} F^+_{j+\frac{1}{2}} + \frac{u_j^2}{2} F^-_{j+\frac{1}{2}} \tag{2.13}$$

and the remainder reads

$$R_j = \frac{1}{2 \delta t} \rho_j (\pi_j - u_j)^2 + \frac{1}{\delta x_j} \left( \frac{(u_j - u_j - 1)^2}{2} F^+_{j+\frac{1}{2}} - \frac{(u_{j+1} - u_j)^2}{2} F^-_{j+\frac{1}{2}} \right)$$

$$+ \frac{1}{\delta x_j} \left( (\pi_j - u_j)(u_j - u_{j+1}) F^+_{j+\frac{1}{2}} + \frac{1}{\delta x_j} (\pi_j - u_j)(u_{j+1} - u_j) F^-_{j+\frac{1}{2}} \right). \tag{2.14}$$

It motivates to define the source term for (2.11) as follows

$$S_{j+\frac{1}{2}} = \frac{\delta x_{j+1} R_{j+1} + \delta x_j R_j}{2 \delta x_{j+\frac{1}{2}}}.$$

The scheme shares similarities with the 1D version of the scheme presented in [30, Section 4], see also [49, Chapter 2] and [24]. However, it differs by the following two points:

- firstly, the mass fluxes in [24,28,30,49] are upwinded with respect to the material velocity (in other words, it corresponds to the choice $F^\pm(\rho,c,u) = \pm \rho[u]^\pm$ instead of (2.5) and (2.6), see also Fig. 2). The mass flux based (2.5) and (2.6) introduces a bit of numerical diffusion [5, Appendix B] which prevents the occurrence of spurious oscillations when the material velocity vanishes, see [29, Section 6.1.1] and [49, Section 2.3.5] where an artificial viscosity is added to damp these oscillations.

- secondly, the organization of the time steppings are different: even if both schemes are explicit, the variables are not updated in the same order. We solve the discrete equations in the order $\rho \rightarrow u \rightarrow e$, as in [1], whereas [30] proceeds according to $\rho \rightarrow e \rightarrow u$. In particular, here the corrective term $S_{j+\frac{1}{2}}$ does not need any time shift since the updated velocity $\bar{u}$ is known when solving (2.11).

### 2.4 Stability conditions

We now turn to the study of the stability conditions which ensure the positivity of the density and the internal energy. We start by stating a lemma that will be useful in this section and in Section 3.3. This lemma about the flux functions $F^\pm$ is proved in [5].
Lemma 2.1. For all \( u \in \mathbb{R} \), for all \( \rho > 0 \) and for all \( c > 0 \), the fluxes \( \mathcal{F}^\pm \) satisfy the following inequalities:

\[
0 \leq \mathcal{F}^+(\rho, c, u) \leq \rho [\lambda_+(c, u)]^+ \quad \text{and} \quad -\rho [\lambda_-(c, u)]^- \leq \mathcal{F}^-(\rho, c, u) \leq 0.
\]

(2.15)

With this lemma at hand, we can prove the following statement.

Proposition 2.2. Assume that \( e_{j+\frac{1}{2}} \geq 0 \), \( \rho_{j+\frac{1}{2}} \geq 0 \), for any \( j \). If the following CFL-like conditions hold for all \( j \)

\[
\frac{\delta t}{\delta x_{j+\frac{1}{2}}} \left( [u_{j+1}]^+ + \frac{c_f(e_{j+\frac{1}{2}}) + c_f(e_{j+\frac{1}{2}})}{\sqrt{2}} + [u_{j}]^- + \frac{c_f(e_{j+\frac{1}{2}}) + c_f(e_{j-\frac{1}{2}})}{\sqrt{2}} \right) \leq \frac{1}{\gamma},
\]

(2.16)

\[
\frac{\delta t}{\delta x_{j+\frac{1}{2}}} c_f(e_{j+\frac{1}{2}}) \leq \frac{(\gamma-1)}{2\sqrt{2}}, \quad \forall k \in \{-1,0,1\},
\]

(2.17)

then \( e_{j+\frac{1}{2}} \geq 0 \) and \( \rho_{j+\frac{1}{2}} \geq 0 \).

Roughly speaking, the stability condition has the expected form of a constraint governed by the speed \( |u| + c \). However, in contrast to what happened for the barotropic case [5, Proposition 3.7], we observe that the expression of the constraint involves additional factors depending on the adiabatic exponent \( \gamma \). This has to be compared to [30, eq. (39)].

Proof. We assume that \( e_{j+\frac{1}{2}} \geq 0 \), \( \rho_{j+\frac{1}{2}} \geq 0 \) and that (2.16) and (2.17) holds for all \( j \). We start by observing that

\[
[\lambda_\pm(c,u)]^\pm \leq [u]^\pm + c,
\]

(2.18)

\[
\sqrt{2} c_j \leq c_f(e_{j-\frac{1}{2}}) + c_f(e_{j+\frac{1}{2}}).
\]

(2.19)

Positivity of the density. As proved in [5], the positivity of \( \bar{\rho}_{j+\frac{1}{2}} \) comes from the inequality

\[
\frac{\delta t}{\delta x_{j+\frac{1}{2}}} ([\lambda_+(c_{j+1}, u_{j+1})]^+ + [\lambda_-(c_j, u_j)]^-) \leq 1.
\]

It is directly implied by (2.16) since \( \gamma > 1 \) and (2.18), (2.19) hold.

Positivity of the internal energy. We rewrite the terms \( (-1)^i [\Pi_{j+\frac{1}{2}} \bar{\rho}_{j+i}, i \in \{0,1\}, which are involved in (2.11), by making the discrete time derivative \( (\bar{\rho}_{j+i} - u_{j+i}) \) appear. Then, we make use of the Young inequality as follows

\[
(-1)^i [\Pi_{j+\frac{1}{2}} \bar{\rho}_{j+i} = (-1)^i (\gamma-1) \left( \rho_{j+\frac{1}{2}} e_{j+\frac{1}{2}} (\bar{\rho}_{j+i} - u_{j+i}) + \rho_{j+\frac{1}{2}} e_{j+\frac{1}{2}} u_{j+i} \right)
\]

\[
\geq -\rho_{j+\frac{1}{2}} \left( \frac{c_f(e_{j+\frac{1}{2}})}{2\sqrt{2}} - (\bar{\rho}_{j+i} - u_{j+i})^2 + (\gamma-1)e_{j+\frac{1}{2}} \left( \frac{c_f(e_{j+\frac{1}{2}})}{\sqrt{2}} - (-1)^i u_{j+i} \right) \right) .
\]

Next, we write \( \bar{\rho}_{j+\frac{1}{2}} \bar{E}_{j+i} \geq T_0 + T_{10} + T_1 \) where:

\[
T_0 = \rho_{j+\frac{1}{2}} e_{j+\frac{1}{2}} \left( 1 - \frac{\delta t}{\delta x_{j+\frac{1}{2}}} (\gamma-1) \left( \frac{c_f(e_{j+\frac{1}{2}})}{\sqrt{2}} - u_j + u_{j+1} \right) \right) - \frac{\delta t}{\delta x_{j+\frac{1}{2}}} \bar{E}_{j+1} - \bar{E}_j,
\]

\[
T_1 = \frac{\delta t}{\delta x_{j+\frac{1}{2}}} [\bar{E}_{j+i} - R_{j+i} - \frac{\delta t}{\delta x_{j+\frac{1}{2}}} c_f(e_{j+\frac{1}{2}}) \rho_{j+\frac{1}{2}} (\bar{\rho}_{j+i} - u_{j+i})^2].
\]

In order to guarantee that \( \bar{E}_{j+\frac{1}{2}} \) is non negative it is sufficient to ensure that these three terms are non negative. This holds under the assumptions (2.16) and (2.17).
Indeed, using the definition of the flux $\mathcal{E}_j$ and owing to (2.15), we obtain

$$\begin{align*}
T_0 \geq \rho_j + \frac{e_j}{2}, \quad & \left(1 - \frac{\delta t}{\delta x_j + \frac{1}{2}} (\gamma - 1) \left( |u_j| - \frac{c_f(e_j + \frac{1}{2})}{2} + [u_{j+1}]^+ + \frac{c_f(e_j + \frac{1}{2})}{\sqrt{2}} \right) \right) \\
& - \frac{\delta t}{\delta x_j + \frac{1}{2}} \rho_j + \frac{e_j + \frac{1}{2}}{2} ([\lambda_+ (e_j + 1, u_{j+1})]^+ + [\lambda_- (c_j, u_j)]^-) 
\end{align*}$$

where, due to (2.16), the right hand side is non negative by virtue of (2.18) and (2.19).

Next, we turn to $T_1^i$. Using twice the Young inequality and bearing in mind the definition of $\mathcal{P}_j$, we observe that

$$\frac{\delta t}{2} \frac{\delta x_{j+1}}{\delta x_j + \frac{1}{2}} R_{j+1}^i \geq \frac{\delta x_{j+1}}{4 \delta x_j + \frac{1}{2}} (\pi_{j+1} - u_{j+1})^2 \left( \rho_j + \frac{1}{2} \frac{\delta t}{\delta x_j + \frac{1}{2}} (\mathcal{E}_{j+1}^+ - \mathcal{E}_{j+1}^-) \right).$$

Hence, we have

$$T_1^i \geq \frac{\delta x_{j+1}}{4 \delta x_j + \frac{1}{2}} (\pi_{j+1} - u_{j+1})^2 \left( \rho_j + \frac{1}{2} \frac{\delta t}{\delta x_j + \frac{1}{2}} (\mathcal{E}_{j+1}^+ - \mathcal{E}_{j+1}^-) \right).$$

Coming back to (2.3) and (2.9), we write $T_1^i \geq \frac{(\pi_{j+1} - u_{j+1})^2}{4 \delta x_j + \frac{1}{2}} \left( T_2^{i,0} + T_2^{i,1} \right)$ where, for $k = 0, 1$,

$$T_2^{i,k} = \frac{\delta x_{j+i+k-\frac{1}{2}}}{2} \rho_j + \frac{e_j + \frac{1}{2}}{2} - \frac{\delta t}{\delta x_{j+i+k-\frac{1}{2}} - \mathcal{E}_{j+i+k-\frac{1}{2}} - \mathcal{E}_{j+i+k-\frac{1}{2}} - \frac{\delta t}{\gamma \sqrt{2}} \rho_j + \frac{e_j + \frac{1}{2}}{2}.$$}

Note that a non negative term has been added to obtain a symmetric formulation in the above inequality. Due to (2.15) and (2.16) we get

$$\mathcal{E}_{j+i+k}^+ - \mathcal{E}_{j+i+k-1}^- \leq \frac{\delta x_{j+i+k-\frac{1}{2}}}{\gamma \delta t} \rho_j + \frac{e_j + \frac{1}{2}}{2}$$

and this allows us to write

$$T_2^{i,k} \geq \frac{\delta x_{j+i+k-\frac{1}{2}}}{2 \gamma} \rho_j + \frac{e_j + \frac{1}{2}}{2} \cdot \left( \gamma - 1 - \frac{\delta t}{\delta x_{j+i+k-\frac{1}{2}} - \mathcal{E}_{j+i+k-\frac{1}{2}} - \mathcal{E}_{j+i+k-\frac{1}{2}} - \frac{\delta t}{\gamma \sqrt{2}} \rho_j + \frac{e_j + \frac{1}{2}}{2} \right).$$

We conclude by observing that this term is non negative by virtue of (2.17).

\section{2.5 Numerical diffusion, contact discontinuities}

It is worth discussing the expression of the numerical diffusion produced by the scheme (see \cite[Appendix B]{5} for a similar discussion concerning the barotropic case). Let us introduce the following non negative quantity

$$C_j = \begin{cases} 
-u_j & \text{if } u_j \leq -c_j, \\
\frac{u_j^2 + c_j^2}{4c_j} & \text{if } |u_j| < c_j, \\
u_j & \text{if } u_j > c_j.
\end{cases}$$

It is convenient to use the following shorthand notations for averaged quantities

$$\{q\}_j = \frac{q_{j-\frac{1}{2}} + q_{j+\frac{1}{2}}}{2} \quad \text{and} \quad \{q\}_{j+1} = \frac{q_{j+\frac{1}{2}} + q_{j+1}}{2}.$$

Finally, we denote

$$\mathcal{F}^\pm = \mathcal{F}^+ - \mathcal{F}^-.$$
which is a positive quantity. The mass and momentum fluxes can be cast as the sum of a centered term and a diffusion term

\[ F_j = \{\rho\} \frac{C_j}{2} (\rho_{j+\frac{1}{2}} - \rho_{j-\frac{1}{2}}), \]

\[ G_{\frac{j+1}{2}} = \{\mathcal{F}\}_{\frac{j+1}{2}} \{u\}_{\frac{j+1}{2}} - \frac{\{\mathcal{F}\}_{\frac{j+1}{2}}}{2} (u_{j+1} - u_j). \]

Concerning the internal energy (2.12) and kinetic energy fluxes (2.13), they become:

\[ E_j = \{\rho e\} \frac{C_j}{2} (e_{j+\frac{1}{2}} \rho_{j+\frac{1}{2}} - e_{j-\frac{1}{2}} \rho_{j-\frac{1}{2}}), \]

\[ K_{\frac{j+1}{2}} = \{\mathcal{F}\}_{\frac{j+1}{2}} \left( \frac{u^2}{2} \right)_{\frac{j+1}{2}} - \frac{\{\mathcal{F}\}_{\frac{j+1}{2}}}{2} \left( \frac{u^2_{j+1} - u^2_j}{2} \right). \]

**Remark 2.3.** As a by-product, it is remarkable that the scheme properly deals with 1D-**contact discontinuities**. Indeed, let us assume that the discrete velocity and pressure are constant in the neighborhood of \( x_{\frac{j+1}{2}} \), which means that \( u_{j-1} = u_j = u_{j+1} = u_{j+2} = u \) and \( \Pi_{j-\frac{1}{2}} = \Pi_{j+\frac{1}{2}} = \Pi_{j+\frac{3}{2}} = \Pi \) holds. Then the scheme guarantees that they remain constant in the neighborhood of this point at the next time: \( \Pi_{\frac{j+1}{2}} = \Pi \) and \( u_{j+1} = u = u_j \).

### 2.6 Conservation of total energy

As said in the introduction, it is far from clear that we can obtain a consistent approximation of the conservation equations (1.2) when the scheme is defined on the basis of the non-conservative formulation (1.4). In order to analyze this issue, let us now introduce the averaged total energy at \( x_{\frac{j+1}{2}} \) and \( x_j \), defined by

\[ E_{\frac{j+1}{2}} = e_{\frac{j+1}{2}} + \frac{1}{2} \frac{\delta x_j \rho_j u^2_j + \delta x_{j+1} \rho_{j+1} u^2_{j+1}}{\delta x_{\frac{j+1}{2}} \rho_{\frac{j+1}{2}}}, \]

and

\[ E_j = \frac{u^2_j}{2} + \frac{\delta x_{\frac{j+1}{2}} \rho_{\frac{j+1}{2}} e_{\frac{j+1}{2}} + \delta x_{\frac{j-1}{2}} \rho_{\frac{j-1}{2}} e_{\frac{j-1}{2}}}{2 \delta x_j \rho_j}. \]

Note that, by definition of \( \delta x_j \), \( E_j \) involves a **convex** combination of the internal energies stored in \( x_{j+\frac{1}{2}} \). In contrast, \( E_{\frac{j+1}{2}} \) involves a linear combination of the kinetic energies which can be non-convex for non uniform grids. We wish to obtain conservative equations for those quantities. To this end, we introduce the fluxes

\[ T_j = E_j + \frac{K_{\frac{j+1}{2}} + K_{\frac{j-1}{2}}}{2} \]

and

\[ T^*_j = \frac{E_{j+1} + E_j + K_{\frac{j+1}{2}}}{2} - \frac{\delta x_{j+1} R_{j+1} - \delta x_j R_j}{4} \]

which use the quantities defined in (2.12), (2.13), (2.14). Note that the flux \( T^*_j \) keeps a contribution depending on the reminders, which, in general, does not vanish.
By combining the internal energy discrete equation (2.11) and the kinetic energy balance, let us compute

$$\frac{\rho_{j+\frac{1}{2}} E_{j+\frac{1}{2}} - \rho_{j+\frac{1}{2}} E_{j+\frac{1}{2}}}{\delta t} = -\frac{E_{j+1} - E_j}{\delta x_{j+\frac{1}{2}}} - \Pi_{j+\frac{1}{2}} \frac{\nabla_j + \nabla_j}{\delta x_{j+\frac{1}{2}}} + S_{j+\frac{1}{2}} - \frac{K_{j+\frac{1}{2}} - K_{j+\frac{1}{2}} + K_{j+\frac{1}{2}} - K_{j-\frac{1}{2}}}{2\delta x_{j+\frac{1}{2}}}$$

Re-arranging the terms, we get the following consistent local balance equations for the total energy $$\rho_{j+\frac{1}{2}} E_{j+\frac{1}{2}}$$ defined on the primal mesh

$$\frac{\rho_{j+\frac{1}{2}} E_{j+\frac{1}{2}} - \rho_{j+\frac{1}{2}} E_{j+\frac{1}{2}}}{\delta t} + \frac{T_{j+1} - T_j}{\delta x_{j+\frac{1}{2}}} + \frac{\Pi_{j+1} \Pi_{j+1} - \Pi_j \Pi_j}{\delta x_{j+\frac{1}{2}}} = 0.$$

Similarly, for the total energy $$\rho_j E_j$$ on the dual mesh, we get

$$\frac{\rho_j E_j - \rho_j E_j}{\delta t} + \frac{T_{j+\frac{1}{2}} - T_j}{\delta x_j} + \frac{\Pi_{j+\frac{1}{2}} \Pi_{j+\frac{1}{2}} - \Pi_j \Pi_j}{\delta x_j} = 0,$$

with the “hybrid” flux $$T_{j+\frac{1}{2}}$$. We thus obtain in both cases a conservative discrete equation. Note that this construction of a local conservation equation for an averaged total energy also holds for the extension to higher dimensions on MAC grids presented in Section 4 and also for an extension of this scheme on unstructured meshes. It will be explained in a forthcoming work, see [39].

### 3 A MUSCL-scheme on staggered grids

In this section we discuss how we adapt the MUSCL principles [52] to the staggered framework. Classically, we first reconstruct second order quantities at edges of primal or dual cells depending on the domain of definition of the different variables. Then, concerning the discretization of the mass flux, we keep unchanged the velocity defined at the interface $$x_j$$ and we shall replace the UpWind value $$\rho_{j+\frac{1}{2}}$$ by a MUSCL reconstruction $$\rho^j_{mcl}$$ of the density: it defines the upgraded mass flux $$F^{JL}_{j+\frac{1}{2}}$$. For the momentum flux, since the discretization of the pressure is centered, we only need to define the convection flux $$G^{JL}_{j+\frac{1}{2}}$$: we shall combine the obtained mass fluxes $$F^{JL}_{j+\frac{1}{2}}$$ and $$F^{JL}_{j+\frac{1}{2}}$$ with a MUSCL reconstructed velocity $$u_{j+\frac{1}{2}}^\pm$$ at the interfaces $$x_{j+\frac{1}{2}}$$. When considering full Euler equation, for the internal energy fluxes, a first attempt would follow the same strategy by combining the upgraded mass fluxes $$F^{JL}_{j+\frac{1}{2}}$$ with a MUSCL reconstructed internal energy $$e_{j+\frac{1}{2}}^\pm$$. However, this approach produces a bad behaviour of the scheme when contact discontinuities occur, see [49] for further comments on this issue. Instead, we combine the upgraded mass fluxes $$F^{JL}_{j+\frac{1}{2}}$$ with a MUSCL reconstruction of the internal energy defined from the ratio $$\frac{(\rho e)^j_+}{\rho_j^+}$$.

We shall see that stability issues might require to strengthen the limitation procedure applied to define the reconstructed velocities $$u_{j+\frac{1}{2}}^\pm$$. 

12
3.1 MUSCL reconstruction at edges of primal or dual mesh

We introduce piecewise linear reconstructions of the mass density $\rho$ and of the density of internal energy $\rho_e$, defined, on each cell $C_{j+\frac{1}{2}}$, by

$$
\hat{q}_{j+\frac{1}{2}}(x) = q_{j+\frac{1}{2}} + s_{j+\frac{1}{2}}(x - x_{j+\frac{1}{2}}), \text{ for any } x \in C_{j+\frac{1}{2}} \text{ and with } q = \rho \text{ or } \rho_e. \quad (3.1)
$$

The slope $s_{j+\frac{1}{2}} \in \mathbb{R}$ is intended to be an approximation of the gradient of $q$ on the cell $C_{j+\frac{1}{2}}$. Classically, it is obtained as a symmetric function of the two discrete derivatives computed using the values of $q$ on the neighboring cells,

$$
\frac{s_{j+\frac{1}{2}}}{\delta x_{j+1}} = \Phi \left( \frac{q_{j+\frac{1}{2}} - q_{j-\frac{1}{2}}}{\delta x_j}, \frac{q_{j+\frac{3}{2}} - q_{j+\frac{1}{2}}}{\delta x_{j+1}} \right).
$$

A suitable adaptation of this formula needs to be introduced at the boundaries of the computational domain; for instance we can simply make the scheme degenerate to first order next to the boundaries ($s_{j+\frac{1}{2}} = 0$ and $s_{j+\frac{3}{2}} = 0$).

For stability reasons, in order to prevent the formation of over- and undershoots, the value of the reconstructed quantities at an edge should not exceed the values of the quantity in the two neighboring cells and the slope $s_{j+\frac{1}{2}}$ should vanish at extrema. These properties are classically ensured by the definition of the function $\Phi$, the so-called limiter function. It is seen here as a function of two variables $(a, b)$ but it is also customary to use instead a function $\Phi$ of the single variable $a/b$ with the following equalities

$$
\hat{\Phi}(a, b) = b \Phi \left( \frac{a}{b} \right) = a \Phi \left( \frac{b}{a} \right) = \Phi(b, a),
$$

where it is understood that the function $\Phi$ satisfies the symmetry property

$$
\Phi(r) = \Phi \left( \frac{1}{r} \right), \forall r \neq 0. \quad (3.2)
$$

On uniform grids, the geometric properties stated above are ensured when the limiter function lies in the well-known Sweby TVD region, see [48, 52], which is characterized by the three conditions

$$
\begin{align*}
\Phi(r) &= 0, \forall r \leq 0, \\
0 &\leq \left( \frac{\Phi(r)}{r} \right), \forall r \geq 0. \\
\end{align*}
$$

On non-uniform grids, the situation is more intricate as explained in [3]: in condition (c) the upper bound 2 should be replaced by a quantity that depends on the mesh regularity. More precisely the limiter $\Phi$ must satisfy

$$
\begin{align*}
\Phi(r) &= 0, \forall r \leq 0, \\
0 &\leq \left( \frac{\Phi(r)}{r} \right) \leq \tau, \forall r \geq 0, \\
\end{align*}
$$

where $1 < \tau \leq 2$ is the mesh dependent number defined by

$$
\tau = \min_{j \in \{2, J-1\}} \left( \frac{2\delta x_j}{\delta x_{j+\frac{1}{2}}}, \frac{2\delta x_{j+1}}{\delta x_{j+\frac{1}{2}}} \right).
$$

We will that a strengthened version is needed for the approximation of the full Euler equation, for which we assume that

$$
\tau < 2. \quad (3.4)
$$
The role of this last restriction will appear in the stability analysis for proving the positivity of the internal energy (see Section 3.3).

Finally, in order to ensure that the scheme is second order in space (see Section 3.4 below), the limiter function \( r \mapsto \Phi(r) \) should be a smooth function – with at least left and right derivatives at the point \( r = 1 \) – and satisfy
\[
\Phi(1) = 1. \tag{3.5}
\]

As discussed in Lemma 3.6 (in Section 3.4 below), if \( x \mapsto q(x) \) is a smooth function with bounded derivatives, then we get
\[
s_{j+\frac{1}{2}}^q = q'(x_{j+\frac{1}{2}}) + O(\delta x).
\]

From classical limiters defined for uniform meshes, we can define \( \tau \)-limiters that satisfy properties (3.2), (3.3) and (3.5), see [15]:

- the MinMod limiter: \( \Phi_{mm}(r) = \max(0, \min(1, r)) \), which is actually upper-bounded by 1, and the \( \tau \)-MinMod limiter:
  \[
  \Phi_{\tau,mm}(r) = \max\left(0, \min(r, \tau)\right) \tag{3.6}
  \]

- the SuperBee limiter: \( \Phi_{sb}(r) = \max(0, \min(2r, 1, \min(r, 2))) \), bounded by 2, and the \( \tau \)-SuperBee limiter:
  \[
  \Phi_{\tau,eb}(r) = \max\left(0, \min(\tau r, 1, \min(r, \tau))\right)
  \]

The affine reconstruction \( \hat{q} \) of \( q \) in (3.1) allows us to define the two values \( q^-_j = \hat{q}_j^{-\frac{1}{2}}(x_j) \) and \( q^+_j = \hat{q}_{j+\frac{1}{2}}(x_j) \) at the interface \( x_j \):

- \( q^-_j = q_j - \frac{\delta x_{j+\frac{1}{2}}}{2} s_{j+\frac{1}{2}}^q \)
- \( q^+_j = q_j + \frac{\delta x_{j+\frac{1}{2}}}{2} s_{j+\frac{1}{2}}^q \)

which will be used in the numerical fluxes. As discussed in Lemma 3.6, if \( x \mapsto q(x) \) is a smooth function, bounded with bounded derivatives, then we get
\[
s_{j+\frac{1}{2}}^q = q'(x_{j+\frac{1}{2}}) + O(\delta x),
\]

which can be used to check that the scheme is formally second-order accurate.

A similar reconstruction is used for the velocity on the dual mesh. We set
\[
\tilde{u}_j(x) = u_j + w_j(x - x_j), \quad \forall x \in C_j, \quad \forall j \in [1, J + 1].
\]

The slopes \( w_j \in \mathbb{R} \) are now defined by
\[
w_j = \lambda_j \Phi\left(\frac{u_j - u_{j-1}}{\delta x_{j-\frac{1}{2}}}, \frac{u_{j+1} - u_j}{\delta x_{j+\frac{1}{2}}}\right), \quad \forall j \in [2, J], \quad \text{and} \quad w_1 = 0 = w_{J+1}. \tag{3.7}
\]

Here, the situation is slightly more involved since we have introduced a parameter \( \lambda_j \in [0, 1] \). The value \( \lambda_j = 1 \) corresponds to the usual MUSCL reconstruction. This value is suitable for the discretization of the barotropic Euler equation but, when considering the full Euler equation, the source term \( S_{j+\frac{1}{2}} \) associated to the kinetic energy balance that appears in the internal
energy equation induces further constraints in order to preserve the positivity of the internal energy, which might require to strengthen the limitation of the slope by choosing $\lambda_j < 1$.

The affine reconstruction $\tilde{u}$ of the velocity $u$ allows us to define, at the interfaces $x_{j + \frac{1}{2}}$, $u_{j + \frac{1}{2}}^- = \tilde{u}_j(x_{j + \frac{1}{2}})$ and $u_{j + \frac{1}{2}}^+ = \tilde{u}_{j+1}(x_{j + \frac{1}{2}})$:

$$u_{j + \frac{1}{2}}^- = u_j + \frac{\delta x_{j + \frac{1}{2}}}{2} w_j,$$
$$u_{j + \frac{1}{2}}^+ = u_{j+1} - \frac{\delta x_{j + \frac{1}{2}}}{2} w_{j+1}.$$ 

Here, we bear in mind that $x_j$ and $x_{j+1}$ are not necessarily the mid-points of $C_j$ and $C_{j+1}$ respectively (see Fig. 1); this is the reason why the formula is not expressed by means of $\delta x_{j+1}/2$ and $\delta x_j/2$.

### 3.2 Definition of the second order fluxes

With the reconstructed quantities at hand, we can now define the modified fluxes. We update the density by replacing the mass flux $F_j$ by the MUSCL-flux $F_{j}^{ML}$ defined by

$$F_{j}^{ML} = F^+ (\rho_j^-, c_j, u_j) + F^- (\rho_j^+, c_j, u_j), \quad \forall j \in [2, J],$$

(with the corresponding adaptation at the boundary, for instance we set $F_{1}^{ML} = 0 = F_{J+1}^{ML}$ at the endpoints of the computational domain if the zero-flux condition is imposed). We naturally set

$$F_{j}^{ML+} = F^+ (\rho_j^-, c_j, u_j) \quad \text{and} \quad F_{j}^{ML-} = F^- (\rho_j^+, c_j, u_j).$$

We also introduce the notation

$$F_{j+\frac{1}{2}}^{ML,\pm} = \frac{F_{j}^{ML,\pm} + F_{j+1}^{ML,\pm}}{2}, \quad \text{and} \quad F_{j+\frac{1}{2}}^{ML} = F_{j+\frac{1}{2}}^{ML,+} + F_{j+\frac{1}{2}}^{ML,-}, \quad (3.8)$$

so that the mass balance on dual mesh (2.10) remain valid when replacing the mass flux $F_{j+1/2}$ by the MUSCL-flux $F_{j+1/2}^{ML}$.

The convection part of the momentum flux is given by

$$G_{j+\frac{1}{2}}^{ML} = u_{j+\frac{1}{2}}^- \frac{F_{j}^{ML,+}}{2} + u_{j+\frac{1}{2}}^+ \frac{F_{j}^{ML,-}}{2}, \quad \forall j \in [2, J-1]. \quad (3.9)$$

We set $G_{\frac{3}{2}}^{ML} = \frac{u_{\frac{3}{2}}}{2} F_{\frac{3}{2}}^{ML,-}$ and $G_{j+\frac{1}{2}}^{ML} = \frac{u_{j+\frac{1}{2}}}{2} F_{j+\frac{1}{2}}^{ML,+}$ for the boundary values.

Finally, when considering the full Euler equations, the internal energy flux is given by

$$E_{j}^{ML} = \frac{(pe)^-}{\rho_j^-} F_{j}^{ML,+} + \frac{(pe)^+}{\rho_j^+} F_{j}^{ML,-}.$$ 

We remind the reader that the MUSCL procedure is not applied directly to the internal energy but to the pressure: we evaluate $(pe)^\pm$ and then divide by $\rho^\pm$. This is motivated by the will to obtain a correct treatment of contact discontinuities. Since we wish to satisfy the criterion “if the pressure (and the velocity) is constant in the neighborhood of a point at a certain time, it
will be kept constant at the following time”, it is quite natural to work on the pressure and not the internal energy. The remainder term reads
\[
\delta x_j R_{j}^{ML} = \frac{\delta x_j}{2\delta t} p_j (\pi_j - u_j)^2 \\
\geq \frac{1}{2} (u_j - u_{j-\frac{1}{2}})^2 F_{j-\frac{1}{2}}^{ML,+} - (u_{j+\frac{1}{2}} - u_j)^2 F_{j+\frac{1}{2}}^{ML,-} \\
- (u_j - u_{j-\frac{1}{2}})^2 F_{j+\frac{1}{2}}^{ML,+} + (u_{j+\frac{1}{2}} - u_j)^2 F_{j-\frac{1}{2}}^{ML,-}
\] (3.10)

or
\[
\begin{aligned}
(\pi_j - u_j) F_{j-\frac{1}{2}}^{ML,+} &+ (u_{j+\frac{1}{2}} - u_j) F_{j+\frac{1}{2}}^{ML,-} \\
&- (u_j - u_{j-\frac{1}{2}})^2 F_{j+\frac{1}{2}}^{ML,+} - (u_{j+\frac{1}{2}} - u_j) F_{j-\frac{1}{2}}^{ML,-}.
\end{aligned}
\]

3.3 Stability conditions

Firstly, we exhibit a CFL-condition which ensures that the numerical density remains non-negative. This condition should be fulfilled for the approximation of the solutions of both barotropic and full Euler equations. Next, we discuss the condition required to ensure the non-negativity of the internal energy when considering the full Euler system. We will make use of the properties (2.15) of the flux functions  \( F^{\pm} \) recalled in Lemma 2.1 in Section 2.4.

**Proposition 3.1** (Non negativity of the density). Suppose that the limiter function \( \Phi \) satisfy (3.3) and that \( \rho_{j+\frac{1}{2}} \geq 0 \) holds for all \( j \in \mathbb{J} \). We assume the CFL-like condition
\[
\frac{\delta t}{\delta x_{j+\frac{1}{2}}} \left( |\lambda_-(c_j, u_j)|^+ + |\lambda_+(c_{j+1}, u_{j+1})|^+ \right) \leq \frac{1}{2}, \quad \forall j \in \mathbb{J}, \tag{3.11}
\]
Then the scheme preserves the non-negativity of the density:
\[
\pi_{j+\frac{1}{2}} \geq 0 \quad \text{for all} \quad j \in \mathbb{J}.
\]

**Proof.** We assume that \( \rho_{j+\frac{1}{2}} \geq 0 \) holds for all \( j \in \mathbb{J} \). Let us introduce the following quantities
\[
\alpha_j = \frac{\delta x_{j+\frac{1}{2}}}{2\delta x_j} \Phi \left( \frac{\rho_{j+\frac{1}{2}} - \rho_{j+\frac{1}{2}}}{\delta x_{j+1}} \frac{\delta x_j}{\rho_{j+\frac{1}{2}} - \rho_{j-\frac{1}{2}}} \right),
\]
and
\[
\beta_j = \frac{\delta x_{j+\frac{1}{2}}}{2\delta x_{j+1}} \Phi \left( \frac{\rho_{j+\frac{1}{2}} - \rho_{j-\frac{1}{2}}}{\delta x_j} \frac{\delta x_{j+1}}{\rho_{j+\frac{1}{2}} - \rho_{j+\frac{1}{2}}} \right).
\]
Owing to property (3.3), we readily check that \( 0 \leq \alpha_j \leq 1 \) and \( 0 \leq \beta_j \leq 1 \). Furthermore, the reconstructed densities can be equivalently recast as
\[
\rho_j^+ = (1 - \alpha_j) \rho_{j+\frac{1}{2}} + \alpha_j \rho_{j-\frac{1}{2}} \quad \text{and} \quad \rho_{j+1}^+ = (1 + \alpha_j) \rho_{j+\frac{1}{2}} - \alpha_j \rho_{j-\frac{1}{2}}, \tag{3.12}
\]
or
\[
\rho_j^+ = (1 + \beta_j) \rho_{j+\frac{1}{2}} - \beta_j \rho_{j+\frac{1}{2}} \quad \text{and} \quad \rho_{j+1}^+ = (1 - \beta_j) \rho_{j+\frac{1}{2}} + \beta_j \rho_{j+\frac{1}{2}}. \tag{3.13}
\]
In particular, equalities (3.12) show that
\[
\rho_j^+ \geq \min \left( \rho_{j-\frac{1}{2}}, \rho_{j+\frac{1}{2}} \right) \geq 0, \quad \text{and} \quad \rho_{j+1}^+ \leq 2 \rho_{j+\frac{1}{2}}.
\]
and equalities (3.13) show that
\[ \rho_j^+ < 2 \rho_{j+\frac{1}{2}} \quad \text{and} \quad \rho_{j-1}^- \geq \min \left( \rho_{j-\frac{1}{2}}, \rho_{j+\frac{1}{2}} \right) \geq 0. \]

Reasoning now as in [5, Lemma 3.7], using the sign property of the flux functions $\pm F^\pm \geq 0$, we are led to the following estimate
\[ \bar{\rho}_{j+\frac{1}{2}} \geq \rho_{j+\frac{1}{2}}^+ + \frac{\delta t}{\delta x_{j+\frac{1}{2}}} \left( F^-(\rho_j^+, c_j, u_j) - F^+(\rho_{j+1}^-, c_{j+1}, u_{j+1}) \right). \]

Owing to equation (2.15) and since $\rho_j^+ \geq 0$ and $\rho_{j+1}^- \geq 0$, we obtain
\[ \bar{\rho}_{j+\frac{1}{2}} \geq \rho_{j+\frac{1}{2}}^+ - \frac{\delta t}{\delta x_{j+\frac{1}{2}}} \left( \rho_j^+ [\lambda-(c_j, u_j)]^- + \rho_{j+1}^- [\lambda+(c_{j+1}, u_{j+1})]^+ \right). \]

Next, bearing in mind that $\rho_j^+ < 2 \rho_{j+\frac{1}{2}}$ and $\rho_{j+1}^- < 2 \rho_{j+\frac{1}{2}}$, we find
\[ \bar{\rho}_{j+\frac{1}{2}} \geq \rho_{j+\frac{1}{2}}^+ \left( 1 - \frac{2 \delta t}{\delta x_{j+\frac{1}{2}}} \left( [\lambda-(c_j, u_j)]^- + [\lambda+(c_{j+1}, u_{j+1})]^+ \right) \right). \]

Since it is assumed that $\rho_{j+\frac{1}{2}}^+ \geq 0$, the conclusion $\bar{\rho}_{j+\frac{1}{2}} \geq 0$ is obtained as a consequence of (3.11).

**Remark 3.2.** It is worth pointing out that the CFL condition for the MUSCL scheme is twice more constrained than with the first order scheme in [5, Prop. 3.7]. This is due to the estimate $\rho_j^+ \leq 2 \rho_{j+\frac{1}{2}}$ and $\rho_{j+1}^- \leq 2 \rho_{j+\frac{1}{2}}$.

**Proposition 3.3** (Non negativity of the internal energy). Assume that $e_{j+\frac{1}{2}}^+ \geq 0$, $\rho_{j+\frac{1}{2}}^+ \geq 0$ and that the following CFL-like conditions hold for any $j$
\[ \frac{\delta t}{\delta x_{j+\frac{1}{2}}} \left( u_{j+1}^+ \right) + \frac{c_f(e_{j+\frac{1}{2}}^+)}{\sqrt{2}} + [u_j]^+ \leq \frac{1}{\gamma+3}, \quad (3.14) \]
\[ \frac{\delta t}{\delta x_{j+\frac{1}{2}}} c_f(e_{j+\frac{1}{2}}^+ + k) \leq \frac{\gamma-1}{2 \sqrt{2}} \frac{\gamma}{\gamma+3}, \quad \forall k \in \{-1,0,1\}. \quad (3.15) \]

Then, we can find $\lambda_j \in [0,1]$ (see formula (3.21)) such that $\bar{\rho}_{j+\frac{1}{2}} \geq 0$.

Note that, in comparison to the first order scheme, see Proposition 2.2, the time step is more constrained by a factor $0 < \frac{\gamma}{\gamma+2} < 1$.

**Proof.** We assume that $e_{j+\frac{1}{2}}^+ \geq 0$, $\rho_{j+\frac{1}{2}}^+ \geq 0$ and that (3.14) and (3.15) holds for all $j$. Note that, owing to inequalities (2.18) and (2.19), the condition (3.14) implies (3.11), so that we have $\bar{\rho}_{j+\frac{1}{2}} \geq 0$. We also recall that the reconstructed quantities satisfy the following inequalities (see the proof of Proposition 3.1)
\[ 0 < \overline{\rho}_{j+1}, \rho_j^+ < 2 \rho_{j+\frac{1}{2}} \quad \text{and} \quad 0 < (\rho e)_j^+ < 2 \rho_{j+\frac{1}{2}} e_{j+\frac{1}{2}}. \quad (3.16) \]

In order to analyze the positivity of the internal energy, we go back to the evolution of the discrete kinetic energy, which now reads
\[ \frac{1}{2} \bar{\rho}_j \bar{\rho}_j^2 - \rho_j u_j^2 + \frac{K_{ML}}{2} \frac{\|u_j^+\|^2}{F_j^+} - \frac{\|u_j^-\|^2}{F_j^-} \bigg/ \delta t \bigg/ \delta x_j = - \mathcal{R}_{j}^{ML}, \]
where
\[ K_{j+\frac{1}{2}} = \frac{|u_j^+|^2}{2} F_{j+\frac{1}{2}}^{ML} + \frac{|u_j^-|^2}{2} F_{j+\frac{1}{2}}^{ML}. \]
and (3.16), we obtain

$$
\delta x_j R_{j}^{ML} \geq \frac{\delta x_j}{2\delta t} (\pi_j - u_j)^2 \left( \rho_j - 4 \frac{\delta t}{\delta x_j} (F_{j+\frac{1}{2}}^{ML,+} - F_{j+\frac{1}{2}}^{ML,-}) \right).
$$

(3.17)

Hence, we deduce

$$
\rho_{j+\frac{1}{2}} \geq \frac{\delta x_j}{2\delta t} (\pi_j - u_j)^2 \left( \rho_j - 4 \frac{\delta t}{\delta x_j} (F_{j+\frac{1}{2}}^{ML,+} - F_{j+\frac{1}{2}}^{ML,-}) \right).
$$

Thus, to guarantee that $\rho_{j+\frac{1}{2}}$ is non negative it is sufficient to ensure that these three terms are non negative.

We first consider $T_0$. Using the definition of the flux $E_j^{ML}$ and owing to equations (2.15) and (3.16), we obtain

$$
T_0 = \rho_{j+\frac{1}{2}} e_j + \left( 1 - \frac{\delta t}{\delta x_j} (\gamma - 1) \left( \frac{c(e_j + \frac{1}{2})}{\sqrt{2}} u_j + u_{j+1} \right) \right) - 2 \frac{\delta t}{\delta x_j} \rho_{j+\frac{1}{2}} e_j \left( \pi_{j+\frac{1}{2}} - \pi_j \right)^2.
$$

where, due to (3.14), the right hand side is non negative by virtue of (2.18) and (2.19).

Next, we turn to $T_1$. Owing to Lemma 3.4, we have

$$
\frac{\delta t}{2} \frac{\delta x_j}{\delta x_j} R_{j}^{ML} \geq \frac{\delta x_j}{4\delta x_j} (\pi_j - u_j)^2 \left( \rho_j - 4 \frac{\delta t}{\delta x_j} (F_{j+\frac{1}{2}}^{ML,+} - F_{j+\frac{1}{2}}^{ML,-}) \right).
$$

Hence, we deduce

$$
T_1 = \frac{\delta x_j}{4\delta x_j} (\pi_j - u_j)^2 \left( \rho_j - 4 \frac{\delta t}{\delta x_j} (F_{j+\frac{1}{2}}^{ML,+} - F_{j+\frac{1}{2}}^{ML,-}) \right).
$$

Coming back to (2.3) and! (3.8), we write $T_1 \geq \frac{\pi_j - u_j}{1 + \pi_j - u_j} \left( T_{2,0}^{i} + T_{2,1}^{i} \right)$ where, for $k = 0, 1$,

$$
T_{2,0}^{i} = \frac{\delta x_j}{2} \rho_{j+\frac{1}{2}} \left( 4 \frac{F_{j+\frac{1}{2}}^{ML,+} - F_{j+\frac{1}{2}}^{ML,-}}{\delta x_j} \right) \frac{\delta t}{\gamma} \frac{\rho_{j+\frac{1}{2}} c(e_j + \frac{1}{2})}{\sqrt{2}}.
$$

Note that a non negative term has been added to obtain a symmetric formulation in the above inequality. Due to equation (2.15) and (3.14), we get

$$
F_{j+\frac{1}{2}}^{ML,+} - F_{j+\frac{1}{2}}^{ML,-} \leq \frac{\delta x_j}{(\gamma + 2)\delta t} \rho_{j+\frac{1}{2}} c(e_j + \frac{1}{2}),
$$

and this allows us to write

$$
T_{2,0}^{i,k} \geq \frac{\delta x_j}{2} \rho_{j+\frac{1}{2}} \left( 1 - \frac{4}{\gamma + 3} - \frac{\delta t}{\delta x_j} \frac{2\sqrt{2}}{\gamma} c(e_j + \frac{1}{2}) \right).
$$
We conclude by observing that this term is non negative by virtue of (3.15).

We now go back to the proof of Lemma 3.4.

Proof of Lemma 3.4. We go back to (3.10). For given coefficients \( \alpha_j \geq 0 \), that will be determined later on, we shall use the following Young inequalities

\[

\left| (\nabla_j - u_j)(u_j - u_{j+\frac{1}{2}}^-) F^{ML,+}_{j+\frac{1}{2}} \right| \leq \frac{(\nabla_j - u_j)^2}{2} (1 + \alpha_j) F^{ML,+}_{j+\frac{1}{2}} + \frac{(u_j - u_{j+\frac{1}{2}}^-)^2}{2(1 + \alpha_j)} F^{ML,+}_{j+\frac{1}{2}}

\]

and

\[

\left| (\nabla_j - u_j)(u_{j+\frac{1}{2}}^- - u_j) F^{ML,-}_{j+\frac{1}{2}} \right| \leq \frac{(\nabla_j - u_j)^2}{2} (1 + \alpha_j) F^{ML,-}_{j+\frac{1}{2}} - \frac{(u_j - u_{j+\frac{1}{2}}^+)^2}{2(1 + \alpha_j)} F^{ML,-}_{j+\frac{1}{2}}.

\]

Using (2.10), which still holds for the MUSCL version of the scheme, and the standard Young inequality for the last four terms in (3.10), we are led to

\[

\delta x_j R^{ML}_j \geq \frac{\delta x_j}{2\delta t} (\nabla_j - u_j)^2 R^{(1)}_j + R^{(2)}_j,

\]

with

\[

R^{(1)}_j = \rho_j - \frac{\delta t}{\delta x_j} \left( \left( F^{ML,+}_{j+\frac{1}{2}} - F^{ML,-}_{j+\frac{1}{2}} \right) \right) - \frac{\delta t}{\delta x_j} \left( \left( F^{ML,+}_{j+\frac{1}{2}} - F^{ML,-}_{j+\frac{1}{2}} \right) + (1 + \alpha_j) (F^{ML,+}_{j+\frac{1}{2}} - F^{ML,-}_{j+\frac{1}{2}}) \right),

\]

\[

R^{(2)}_j = \frac{\alpha_j}{2(1 + \alpha_j)} \left( (u_j - u_{j-1}^+)^2 F^{ML,+}_{j+\frac{1}{2}} - (u_{j+\frac{1}{2}}^- - u_j)^2 F^{ML,-}_{j+\frac{1}{2}} \right) + \left( (u_{j+\frac{1}{2}}^- - u_j)^2 F^{ML,-}_{j+\frac{1}{2}} - (u_j - u_{j+1}^-)^2 F^{ML,+}_{j+\frac{1}{2}} \right).

\]

We rewrite

\[

R^{(1)}_j = \left( \rho_j - 4 \frac{\delta t}{\delta x_j} \left( F^{ML,+}_{j+\frac{1}{2}} - F^{ML,-}_{j+\frac{1}{2}} \right) \right) + \frac{\delta t}{\delta x_j} \left( 2(F^{ML,+}_{j+\frac{1}{2}} - F^{ML,-}_{j+\frac{1}{2}}) - \alpha_j(F^{ML,+}_{j+\frac{1}{2}} - F^{ML,-}_{j+\frac{1}{2}}) \right),

\]

so that we get

\[

R^{(1)}_j \geq \rho_j - 4 \frac{\delta t}{\delta x_j} \left( F^{ML,+}_{j+\frac{1}{2}} - F^{ML,-}_{j+\frac{1}{2}} \right)

\]

as soon as

\[

\alpha_j \leq 2A_j \quad \text{with} \quad A_j = \frac{F^{ML,+}_{j+\frac{1}{2}} - F^{ML,-}_{j+\frac{1}{2}}}{F^{ML,+}_{j+\frac{1}{2}} - F^{ML,-}_{j+\frac{1}{2}}}.

\]

Note that the quantity \( A_j \) is well defined and always positive since

\[

F^{ML,+}_{j+\frac{1}{2}} - F^{ML,-}_{j+\frac{1}{2}} \geq (F^{ML,+}_{j+\frac{1}{2}} - F^{ML,-}_{j+\frac{1}{2}})/2 > 0.

\]

We now turn to the study of \( R^{(2)}_j \). Using the following shorthand notation for the discrete derivative

\[

a_{j+\frac{1}{2}} = \frac{u_{j+1} - u_j}{\delta x_{j+\frac{1}{2}}},

\]

19
we remark on one hand that
\[(u_j - u_{j-\frac{1}{2}})^2 = \delta x_{j-\frac{1}{2}}^2 \left( a_{j-\frac{1}{2}} - \frac{\lambda_j-1}{2} \bar{\Phi} \left( a_{j-\frac{1}{2}}, a_{j+\frac{1}{2}} \right) \right)^2 \]
\[\geq \delta x_{j-\frac{1}{2}}^2 a_{j-\frac{1}{2}} \left( 1 - \frac{\lambda_j-1}{2} \right)^2 \]
\[\geq \delta x_{j-\frac{1}{2}}^2 a_{j,m} \left( 1 - \frac{\tau}{2} \right)^2 \]
with \(a_{j,m} = \min \{|a_{j-\frac{1}{2}}|, |a_{j+\frac{1}{2}}|\} \geq 0\). Similarly, we have
\[(u_{j+\frac{1}{2}} - u_j)^2 \geq \delta x_{j+\frac{1}{2}}^2 a_{j,m} \left( 1 - \frac{\tau}{2} \right)^2 ,\]
so that we get
\[(u_j - u_{j-\frac{1}{2}})^2 \mathcal{F}_{j-\frac{1}{2}}^{ML,+} - (u_{j+\frac{1}{2}} - u_j)^2 \mathcal{F}_{j+\frac{1}{2}}^{ML,-} \]
\[\geq \left( \delta x_{j-\frac{1}{2}}^2 \mathcal{F}_{j-\frac{1}{2}}^{ML,+} - \delta x_{j+\frac{1}{2}}^2 \mathcal{F}_{j+\frac{1}{2}}^{ML,-} \right) a_{j,m} \left( 1 - \frac{\tau}{2} \right)^2 . \quad (3.19)\]
On the other hand, since \(|\bar{\Phi}(a,b)| \leq \tau \min(|a|,|b|)\), we have
\[(u_{j-\frac{1}{2}} - u_j)^2 = \frac{\lambda_j^2}{4} \delta x_{j-\frac{1}{2}}^2 \bar{\Phi} \left( a_{j-\frac{1}{2}}, a_{j+\frac{1}{2}} \right) \]
\[\geq \frac{\lambda_j^2}{4} \delta x_{j-\frac{1}{2}}^2 \tau^2 a_{j,m}, \]
so that we have
\[(u_{j-\frac{1}{2}} - u_j)^2 \mathcal{F}_{j-\frac{1}{2}}^{ML,-} - (u_{j+\frac{1}{2}} - u_j)^2 \mathcal{F}_{j+\frac{1}{2}}^{ML,+} \geq -\frac{\lambda_j^2}{4} \tau^2 a_{j,m} \left( \delta x_{j+\frac{1}{2}}^2 \mathcal{F}_{j+\frac{1}{2}}^{ML,+} - \delta x_{j-\frac{1}{2}}^2 \mathcal{F}_{j-\frac{1}{2}}^{ML,-} \right) . \quad (3.20)\]
Thus combining (3.19) and (3.20) we arrive at
\[R_j^{(2)} \geq \frac{\alpha_j}{2(1+\alpha_j)} \delta x_{j-\frac{1}{2}}^2 \mathcal{F}_{j-\frac{1}{2}}^{ML,+} - \delta x_{j+\frac{1}{2}}^2 \mathcal{F}_{j+\frac{1}{2}}^{ML,-} a_{j,m} \left( 1 - \frac{\tau}{2} \right)^2 \]
\[\geq \left( \frac{\alpha_j}{2(1+\alpha_j)} \right) \left( 1 - \frac{\tau}{2} \right)^2 \left( \frac{\lambda_j^2}{4} \tau^2 B_j \right) ,\]
with
\[B_j = \frac{\delta x_{j+\frac{1}{2}}^2 \mathcal{F}_{j+\frac{1}{2}}^{ML,+} - \delta x_{j-\frac{1}{2}}^2 \mathcal{F}_{j-\frac{1}{2}}^{ML,-}}{\delta x_{j+\frac{1}{2}}^2 \mathcal{F}_{j+\frac{1}{2}}^{ML,+} - \delta x_{j-\frac{1}{2}}^2 \mathcal{F}_{j-\frac{1}{2}}^{ML,-}} .\]
Then, \(R_j^{(2)} \geq 0\) provided
\[\lambda_j^2 \left( \frac{\tau}{2} \right)^2 B_j \leq \frac{\alpha_j}{2(1+\alpha_j)} \left( \frac{2-\tau}{2} \right)^2 .\]
To relax the condition on \( \lambda_j \) as far as possible, and bearing in mind the condition (3.18) we set
\[
\alpha_j = 2A_j
\]
so that we are reduced to check that
\[
\lambda_j^2 \leq \left( \frac{2 - \tau}{\tau} \right)^2 \frac{A_j}{(1+2A_j)B_j}.
\]
Therefore it is sufficient to set
\[
\lambda_j = \frac{2 - \tau}{\tau} \frac{1}{\sqrt{1+2A_j} \sqrt{B_j}}.
\] (3.21)

**Remark 3.5.** The case \( \lambda_j = 1 \) corresponds to the second order (except for extrema, where the gradient is zero and the scheme degenerates to order 1 due to the limiter) while \( \lambda_j = 0 \) corresponds to the first order. Note that assumption (3.4) on the limiter allows us to make use of positive values of \( \lambda_j \) since \( \tau \) is assumed to be strictly less than 2. On uniform grids, equation (3.21) becomes
\[
\lambda_j = \frac{2 - \tau}{\tau} \frac{1}{\sqrt{1+2A_j}},
\]
so that the coefficient \( \lambda_j \) satisfies \( 0 < \lambda_j < 1 \). However, setting \( \lambda_j < 1 \) implies a loss of accuracy compared to the pure second-order **muscl** scheme. Thus, in practice, we adopt the following strategy:

- we first set \( \lambda_j = 1 \) and compute the discrete internal energies \( e_{j+\frac{1}{2}} \).
- if we obtain a negative value for \( e_{j+\frac{1}{2}} \), meaning that (3.17) is not satisfied for \( R_j \) and/or \( R_{j+1} \), we modify the value of \( \lambda_j \) and/or \( \lambda_{j+1} \) following (3.21) to ensure (3.17) for both \( R_j \) and \( R_{j+1} \).
- we compute the new values for \( \Pi_{j-1}, \Pi_j, \Pi_{j+1}, R_{j-1}, R_j, R_{j+1}, e_{j-\frac{1}{2}}, e_{j+\frac{1}{2}}, e_{j+\frac{3}{2}} \) and/or \( \Pi_j, \Pi_{j+1}, R_j, R_{j+1}, R_{j+2}, e_{j+\frac{1}{2}}, e_{j+\frac{3}{2}} \).

Nevertheless, we observe that, in practice, it is quite infrequent in the simulations that the criterion that requires to reduce \( \lambda_j \) is activated. Indeed, none the simulations that we are going to show in the last section of this chapter has needed this criterion. Besides, we point out that the scheme designed in [49, Chapter 2] adapts a **muscl** reconstruction on the density and on the internal energy fluxes only, the convection fluxes for the momentum equation remain the first order fluxes (that corresponds here to always set \( \lambda_j = 0 \)). Note also that the stability conditions in [49] are slightly different, precisely because the fluxes in this scheme are based on the material velocity only. However, it requires in certain circumstances (vanishing velocities, low Mach regimes) to introduce artificial diffusion.

### 3.4 Consistency of the scheme

Let us briefly check the consistency of the scheme, showing it can reach the second order accuracy for smooth solutions, and far away from extrema (since otherwise the limiter reduces the order of the approximation) when \( \lambda_j \) is set to 1 for all \( j \) in (3.7). To this end, we study (at a fixed time) the consistency of the fluxes. The time being fixed, we consider smooth functions \( \rho, u \) and \( e \) (when considering full Euler system) of the space variable \( x \) only (say of class \( C^1 \) with bounded and not vanishing derivatives). We set \( \rho_{j+\frac{1}{2}} = \rho(x_{j+\frac{1}{2}}), e_{j+\frac{1}{2}} = e(x_{j+\frac{1}{2}}) \) and \( u_j = u(x_j) \)
and insert these quantities in the scheme instead of $\rho_{j+1/2}^+$, $e_{j+1/2}$ and $u_j$. We denote with an underline all the quantities (slopes, reconstructed densities, pressure and velocities, fluxes...) defined in this way from $\rho_{j+1/2}^-$, $\rho e_{j+1/2}$ and $u_j$. The first observation, stated in Lemma 3.6, is that the reconstructed densities $\rho_j^\pm$ and velocities $u_j^\pm$ are second order approximations of $\rho(x_j)$ and $u(x_j)$, respectively.

**Lemma 3.6.** The following equalities hold (when $\lambda_j$ is set to 1 for all $j$ in (3.7)):

$$
\rho_j^+ = \rho(x_j) + \mathcal{O}(\delta x^2), \quad \forall j \in [1, J-1], \\
\rho_j^- = \rho(x_j) + \mathcal{O}(\delta x^2), \quad \forall j \in [2, J],
$$

(3.22)

$$
u_j^+ = \nu(x_{j+1/2}) + \mathcal{O}(\delta x^2), \quad \forall j \in [1, J-1], \\
\nu_j^- = \nu(x_{j+1/2}) + \mathcal{O}(\delta x^2), \quad \forall j \in [2, J],
$$

(3.23)

and, when considering full Euler system,

$$
\rho e_j^+ = \rho e(x_j) + \mathcal{O}(\delta x^2) \quad \text{and} \quad \rho e_j^- = \rho e(x_j) + \mathcal{O}(\delta x^2).
$$

(3.24)

**Proof.** We first prove that

$$s_{j+1/2} = \rho'(x_{j+1/2}) + \mathcal{O}(\delta x).$$

(3.25)

Indeed, we clearly have

$$\frac{\rho_{j+1/2} - \rho_{j-1/2}}{\delta x_j} = \rho'(x_{j+1/2}) + \mathcal{O}(\delta x), \quad \text{and} \quad \frac{\rho_{j+3/2} - \rho_{j+1/2}}{\delta x_{j+1}} = \rho'(x_{j+1/2}) + \mathcal{O}(\delta x),$$

so that

$$\frac{\rho_{j+3/2} - \rho_{j+1/2}}{\delta x_{j+1}} \cdot \frac{\delta x_j}{\rho_{j+3/2} - \rho_{j+1/2}} = 1 + \mathcal{O}(\delta x).$$

Since $\Phi(1) = 1$ and $r \mapsto \Phi(r)$ admits left and right derivatives at the point $r = 1$ (cf. assumption (3.5)), we get

$$\Phi\left(\frac{\rho_{j+3/2} - \rho_{j+1/2}}{\delta x_{j+1}} \cdot \frac{\delta x_j}{\rho_{j+3/2} - \rho_{j+1/2}} \right) = 1 + \mathcal{O}(\delta x).$$

This last equality together with the definition of $s_{j+1/2}$

$$s_{j+1/2} = \frac{\rho_{j+3/2} - \rho_{j+1/2}}{\delta x_j} \Phi\left(\frac{\rho_{j+3/2} - \rho_{j+1/2}}{\delta x_{j+1}} \cdot \frac{\delta x_j}{\rho_{j+3/2} - \rho_{j+1/2}} \right),$$

proves (3.25). Next, from (3.25) and the definition of $\rho_j^\pm$ we readily find, for all $j \in [1, J]$,

$$\rho_j^+ = \rho_{j+1/2} + \frac{\delta x_{j+1/2}}{2} \rho'(x_{j+1/2}) + \mathcal{O}(\delta x^2),
$$

and

$$\rho_j^- = \rho_{j+1/2} - \frac{\delta x_{j+1/2}}{2} \rho'(x_{j+1/2}) + \mathcal{O}(\delta x^2).$$

The conclusion is then obtained using the following identities, direct consequences of the Taylor-Young expansion,

$$\rho(x_{j+1}) = \rho_{j+1/2} + \frac{\delta x_{j+1/2}}{2} \rho'(x_{j+1/2}) + \mathcal{O}(\delta x^2)
$$

and

$$\rho(x_j) = \rho_{j+1/2} - \frac{\delta x_{j+1/2}}{2} \rho'(x_{j+1/2}) + \mathcal{O}(\delta x^2).$$

The equalities for $u_j^\pm$ or $\rho e_j^\pm$ can be proved by following the same lines. 

22
With Lemma 3.6 at hand, we can now prove that the approximation of the fluxes can reach second order accuracy in space. Concerning the momentum flux, since the pressure is centered we focus on the convective part $\mathcal{G}_{j+\frac{1}{2}}^{ML}$. We can prove the following result.

**Proposition 3.7.** The following equalities hold:

\[
\mathcal{E}_{j}^{ML} = \rho(x_{j})u(x_{j}) + O(\delta x^{2}).
\]  \hspace{1cm} (3.26)

\[
\mathcal{E}_{j+\frac{1}{2}}^{ML} = \rho(x_{j+\frac{1}{2}})u(x_{j+\frac{1}{2}})^{2} + O(\delta x^{2})
\]  \hspace{1cm} (3.27)

When considering the full Euler system, we have also the following results:

\[
\mathcal{L}_{j}^{ML} = \rho(x_{j})u(x_{j})e(x_{j}) + O(\delta x^{2}),
\]

\[
\mathcal{K}_{j+\frac{1}{2}}^{ML} = \rho(x_{j+\frac{1}{2}})\frac{u(x_{j+\frac{1}{2}})^{3}}{2} + O(\delta x^{2}).
\]

**Proof.** By using (2.7), namely $\mathcal{F}^{+}(\rho,u) + \mathcal{F}^{-}(\rho,u) = \rho u$, we start by rewriting the mass flux as follows

\[
\mathcal{E}_{j}^{ML} = \frac{\rho_{j}^{+} + \rho_{j}^{-}}{2}u_{j} + \mathcal{F}^{+}\left(\rho_{j}^{-}, u_{j}\right) - \mathcal{F}^{-}\left(\rho_{j}^{+}, u_{j}\right),
\]

where the function $\mathcal{F}^{\pm}$ is defined by $\mathcal{F}^{\pm}(\rho,u) = \mathcal{F}^{+}(\rho,u) - \mathcal{F}^{-}(\rho,u) \geq 0$. Owing to (3.22), we readily find that

\[
\frac{\rho_{j}^{+} + \rho_{j}^{-}}{2}u_{j} = \rho(x_{j})u_{j} + O(\delta x^{2}).
\]

Furthermore, since the function $(\rho,u) \mapsto \mathcal{F}^{\pm}(\rho,u)$ is of class $C^{1}$ (see [5, Lemma 3.3]), we have

\[
\mathcal{F}^{\pm}\left(\rho(x_{j}), u_{j}\right) = \mathcal{F}^{\pm}\left(\rho_{j}^{+}, u_{j}\right) + O(\delta x^{2}).
\]

Thus, we find

\[
\frac{\mathcal{F}^{\pm}\left(\rho_{j}^{-}, u_{j}\right) - \mathcal{F}^{\pm}\left(\rho_{j}^{+}, u_{j}\right)}{2} = O(\delta x^{2})
\]

and (3.26) is proved.

We turn to momentum flux. By using (3.23), and bearing in mind definition (3.9) of $\mathcal{G}_{j+\frac{1}{2}}^{ML}$, we first observe that

\[
\mathcal{G}_{j+\frac{1}{2}}^{ML} = \mathcal{E}_{j+\frac{1}{2}}^{ML} = \frac{\mathcal{E}_{j+1}^{ML,-} + \mathcal{E}_{j+1}^{ML,+}}{2} + \mathcal{F}_{j+\frac{1}{2}}^{ML,-} + \mathcal{F}_{j+\frac{1}{2}}^{ML,+}
\]

\[
= \mathcal{E}_{j+\frac{1}{2}}^{ML} + O(\delta x^{2}).
\]

We then use (3.26) to find

\[
\mathcal{G}_{j+\frac{1}{2}}^{ML} = \mathcal{E}_{j+\frac{1}{2}}^{ML} = \frac{\rho(x_{j})u(x_{j}) + \rho(x_{j+1})u(x_{j+1})}{2} + O(\delta x^{2}).
\]

The conclusion (3.27) is then obtained since we have

\[
\frac{\rho(x_{j})u(x_{j}) + \rho(x_{j+1})u(x_{j+1})}{2} = \rho(x_{j+\frac{1}{2}})u(x_{j+\frac{1}{2}}) + O(\delta x^{2}).
\]

The results for $\mathcal{L}_{j}^{ML}$ and $\mathcal{K}_{j+\frac{1}{2}}^{ML}$ are obtained by following the same lines. 

\[
\]
The second order accuracy can equally be reached with respect to the time variable, by using the Runge-Kutta discretization (RK2) for approximating the time derivative. In the barotropic case, the RK2 scheme can be classically stated as follows. Starting from \( W = (\rho, u) \) the set of unknowns at time \( t \), its update \( W \) at time \( t + \delta t \) is built by using the following algorithm

\[
\begin{align*}
W^{(1)} &= W, \\
W^{(2)} &= W + \frac{\delta t}{2} K_1, \\
W &= W + \delta t K_2,
\end{align*}
\]

where the quantity \( F(W) \) is obtained by evaluating the mass and momentum fluxes using the data \( W \), so that the first order Euler scheme could be stated as \( \bar{W} = W + \delta t F(W) \). For the full Euler system, the situation is more intricate since the update of the internal energy involves the updated density \( \bar{\rho} \) and the updated velocity \( \bar{u} \) (see (2.11)). As pointed out in [24, Appendix A], the application of a second order Runge Kutta procedure for a system where one uses the new value of certain components to update the remaining ones might lead to a scheme which is only first order accurate. Therefore some caution is necessary in the treatment of the internal energy equation. We use the notation \( \bar{F} (\bar{W}, W) \) for the evaluation of mass, momentum, internal energy fluxes, of the non-conservative term \( p \nabla \cdot u \) and \( S \), so that the first order Euler scheme can be written as \( \bar{W} = W + \delta t \bar{F}(W) \), where \( W \) now stands for the triple \((\rho, u, e)\). We remind the reader that the scheme has an implicit flavor, but densities \( \rho \) and velocities \( u \) are obtained by using only \( W \), so that the computation of \( e \), which only needs \((\rho, u)\) in \( W \), is direct. The second order scheme we use can be stated as follows

\[
\begin{align*}
W^{(1)} &= W, \\
W^{(2)} &= W + \frac{\delta t}{2} K_1, \\
W^{(3)} &= W + \frac{\delta t}{2} K_2, \\
\bar{W} &= W + \delta t K_2,
\end{align*}
\]

Note that in the case where \( \bar{F} (\bar{W}, W) \) does not depend on \( \bar{W} \) this is exactly the standard RK2 scheme. This time discretization is formally second order accurate but it is not clear whether it preserves the positivity of the density and the internal energy. We do not observe any difficulty in the numerical tests.

4 Higher dimensions on MAC grids

As far as we restrict to Cartesian grids, our approach can be easily extended to higher dimensions since the discretization can be interpreted by means of the MAC framework. Dealing with general meshes in higher dimension is much more intricate [7,8,13,15,46] and beyond the scope of the present paper, see [39].

Remark 4.1. It is worth mentioning here the recent work by C. Berthon, Y. Coudière and V. Desveaux [9,10] who develop a high order scheme on unstructured meshes for the barotropic Euler system by doubling the set of numerical unknowns: the conserved quantities \( U = (\rho, \rho u) \) are stored on both the primal and the dual cells. This approach is very appealing in the multi-dimensional case since it provides naturally a way to define full gradients on the interface of the control volumes of an unstructured mesh. Note also that the definition of limiters on general
unstructured meshes gives rise to challenging issues, see [12, 13, 15] and the references therein. Here we are only concerned with the simpler situation of Cartesian grids and the scheme does not need to double all variables. Note also that in the present framework it is more adapted to work with the physical quantities $\rho$ and $u$.

Let us explain how the scheme works in dimension two for the barotropic Euler system. The application to the full Euler system is left to the reader. The computational domain is the square

$$\Omega = [a_x, b_x] \times [a_y, b_y] \subset \mathbb{R}^2,$$

and we thus aim at writing the scheme for the PDE system

$$\partial_t \begin{pmatrix} \rho \\ \rho u \\ \rho v \end{pmatrix} + \partial_x \begin{pmatrix} \rho u^2 + p(\rho) \\ \rho u v \\ \rho v^2 + p(\rho) \end{pmatrix} = 0.$$

We define the meshes as follows:

- The primal mesh is defined by the points

$$a_x = x_1 < x_2 < \ldots < x_{i-1} < x_i < x_{i+1} < \ldots < x_M < x_{M+1} = b_x,$$

and

$$a_y = y_1 < y_2 < \ldots < y_{j-1} < y_j < y_{j+1} < \ldots < y_N < y_{N+1} = b_y.$$

- Then we define the midpoints

$$x_{i+\frac{1}{2}} = \frac{x_i + x_{i+1}}{2}, \quad \forall i \in \{1, M\}, \quad \text{and} \quad y_{j+\frac{1}{2}} = \frac{y_j + y_{j+1}}{2}, \quad \forall j \in \{1, N\}.$$

- We set $\delta x_{i+\frac{1}{2}}, \delta y_{j+\frac{1}{2}}, \delta x_i$ and $\delta y_j$ the length of $[x_i, x_{i+\frac{1}{2}}], [y_j, y_{j+\frac{1}{2}}], [x_{i-\frac{1}{2}}, x_i]$, and $[y_j, y_{j+\frac{1}{2}}]$ respectively.

According to the pioneering approach for incompressible flows in [27], we store the discrete densities, the horizontal and the vertical velocities at different locations, see Fig. 3:

- the density $\rho$ is evaluated at the centers of the primal cells: we are dealing with the numerical unknowns $\rho_{i+\frac{1}{2}, j+\frac{1}{2}}$;

- the horizontal velocity $u$ is evaluated at the centers of the cells $[x_{i-\frac{1}{2}}, x_i] \times [y_j, y_{j+1}]$: the numerical unknowns thus reads $u_{i, j+\frac{1}{2}}$;

- the vertical velocity $v$ is evaluated at the centers of the cells $[x_i, x_{i+1}] \times [y_{j-\frac{1}{2}}, y_j]$: the numerical unknowns thus reads $v_{i+\frac{1}{2}, j}$.

As in 1D, we need an approximation of $\rho$ at the edges of the primal mesh,

$$\rho_{i, j+\frac{1}{2}} = \frac{\delta x_{i+\frac{1}{2}} \rho_{i+\frac{1}{2}, j+\frac{1}{2}} + \delta x_{i-\frac{1}{2}} \rho_{i-\frac{1}{2}, j+\frac{1}{2}}}{2 \delta x_i} \quad \text{and} \quad \rho_{i+\frac{1}{2}, j} = \frac{\delta y_{j+\frac{1}{2}} \rho_{i+\frac{1}{2}, j+\frac{1}{2}} + \delta y_{j-\frac{1}{2}} \rho_{i+\frac{1}{2}, j-\frac{1}{2}}}{2 \delta y_j}.$$
For boundary values, we use here zero fluxes: 

Symmetrically, the mass fluxes are defined, for each value of vertical velocity

The first order scheme is a direct extension of the one proposed in [6] to the 2D framework.

First, the discrete densities \( \rho_{i+\frac{1}{2},j+\frac{1}{2}}, i \in [1,M], j \in [1,N] \), are updated using the following explicit scheme

\[
\frac{\rho_{i+\frac{1}{2},j+\frac{1}{2}} - \rho_{i+\frac{1}{2},j+\frac{1}{2}}}{\delta t} + \frac{F_{i+1,j+\frac{1}{2}} - F_{i,j+\frac{1}{2}}}{\delta x_{i+\frac{1}{2}}} + \frac{F_{i+\frac{1}{2},j+1} - F_{i+\frac{1}{2},j}}{\delta y_{j+\frac{1}{2}}} = 0. 
\]

Fig. 4 illustrate the following construction: the discrete mass fluxes in the \( x \) direction \( F_{i,j+\frac{1}{2}} \) are defined, for each value of \( j \in [1,N] \), as the 1D fluxes, using the values of the horizontal velocity \( u_{i,j+\frac{1}{2}} \) to upwind the density in the horizontal direction

\[
F_{i,j+\frac{1}{2}}^{x} = F_{i,j+\frac{1}{2}}^{x,+} + F_{i,j+\frac{1}{2}}^{x,-}, \quad \forall (i,j) \in [2,M] \times [1,N],
\]

with

\[
F_{i,j+\frac{1}{2}}^{x,+} = F^{+}(\rho_{i-\frac{1}{2},j+\frac{1}{2},u_{i,j+\frac{1}{2}}}) \quad \text{and} \quad F_{i,j+\frac{1}{2}}^{x,-} = F^{-}(\rho_{i+\frac{1}{2},j+\frac{1}{2},u_{i,j+\frac{1}{2}}}).
\]

Symmetrically, the mass fluxes \( F_{i+\frac{1}{2},j}^{y} \) in the \( y \) direction are defined using the values of the vertical velocity \( v_{i+\frac{1}{2},j} \) to upwind the density in the vertical direction

\[
F_{i+\frac{1}{2},j}^{y} = F_{i+\frac{1}{2},j}^{y,+} + F_{i+\frac{1}{2},j}^{y,-}, \quad \forall (i,j) \in [1,M] \times [2,N],
\]

with

\[
F_{i+\frac{1}{2},j}^{y,+} = F^{+}(\rho_{i+\frac{1}{2},j-\frac{1}{2},v_{i+\frac{1}{2},j}}) \quad \text{and} \quad F_{i+\frac{1}{2},j}^{y,-} = F^{-}(\rho_{i+\frac{1}{2},j+\frac{1}{2},v_{i+\frac{1}{2},j}}).
\]

For boundary values, we use here zero fluxes: \( F_{i,j+\frac{1}{2}}^{x} = 0 = F_{M+1,j+\frac{1}{2}}^{x} \) and \( F_{i+\frac{1}{2},j}^{y} = 0 = F_{i+\frac{1}{2},N+\frac{1}{2}}^{y} \).
Next, the horizontal velocities \( u_{i,j+\frac{1}{2}}, \ i \in [2,M], \ j \in [1,N] \) are updated with the following scheme

\[
\frac{\overline{p}_{i,j+\frac{1}{2}} - \rho_{i,j+\frac{1}{2}} u_{i,j+\frac{1}{2}}}{\delta t} + \frac{G_{t+\frac{1}{2},j+\frac{1}{2}} - G_{t-\frac{1}{2},j+\frac{1}{2}}}{\delta x_i} + \frac{\Pi_{t+\frac{1}{2},j+\frac{1}{2}} - \Pi_{t-\frac{1}{2},j+\frac{1}{2}}}{\delta y_j} + \frac{G_{u,j+1} - G_{u,j}}{\delta y_j} = 0. \tag{4.2}
\]

We would define the fluxes \( G_{u,x}^{i+\frac{1}{2},j+\frac{1}{2}} \), resp. \( G_{u,y}^{i+\frac{1}{2},j+\frac{1}{2}} \), by upwinding the horizontal momentum \((\rho u)_{i,j+\frac{1}{2}}, \ i \in [2,M], \ j \in [1,N] \), resp. \((\rho u)_{i,j}, \ i \in [2,M], \ j \in [1,N] \), with respect to the value of the horizontal velocity \( u_{i+\frac{1}{2},j+\frac{1}{2}}, \ i \in [2,M], \ j \in [1,N] \), resp. the vertical velocity \( v_{i,j} \). However, on staggered grids, none of these quantities are obviously defined. As in 1D, we have to bear in mind that, when discretizing the mass conservation equation, we already defined a discrete form of the horizontal, resp. vertical, mass flux based on an upwinding of the density (with respect to the horizontal, resp. vertical, velocity). Thus, the upwinding of horizontal momentum can be next obtained by upwinding the horizontal velocity with respect to the “positive” or “negative” part of the mass fluxes. However, horizontal, resp. vertical, mass fluxes are only defined at points \((x_i,y_{j+\frac{1}{2}})\), resp. \((x_{i+\frac{1}{2}},y_j)\). The first step is thus to define the “positive” and “negative” parts of the horizontal, resp. vertical, mass flux at points \((x_{i+\frac{1}{2}},y_{j+\frac{1}{2}})\), resp. \((x_i,y_j)\). This is done by taking the following mean values

\[
F_{x,+}^{i+\frac{1}{2},j+\frac{1}{2}} = \frac{1}{2} \left( F_{x,+}^{i,j+\frac{1}{2}} + F_{x,+}^{i+1,j+\frac{1}{2}} \right) \quad \text{and} \quad F_{y,0}^{i,j} = \frac{\delta y_j}{2 \delta x_i} \left( F_{y,0}^{i+1,j} - F_{y,0}^{i,j} \right).
\]

Next, for each \( j \in [1,N] \), the momentum fluxes \( G_{u,x}^{i+\frac{1}{2},j+\frac{1}{2}} \) are defined, as in 1D, by

\[
G_{u,x}^{i+\frac{1}{2},j+\frac{1}{2}} = u_{i,j+\frac{1}{2}} F_{x,+}^{i+\frac{1}{2},j+\frac{1}{2}} + u_{i+1,j+\frac{1}{2}} F_{x,-}^{i+\frac{1}{2},j+\frac{1}{2}}, \ \forall i \in [2,M-1].
\]

and

\[
\Pi_{i+\frac{1}{2},j+\frac{1}{2}} = \rho_{i+\frac{1}{2},j+\frac{1}{2}} F_{i+\frac{1}{2},j+\frac{1}{2}}, \ \forall i \in [2,M-1].
\]

For boundary fluxes, as in 1D, we use slightly different definitions

\[
G_{u,x}^{2,j+\frac{1}{2}} = \frac{u_{2,j+\frac{1}{2}}}{2} F_{2,j+\frac{1}{2}}, \text{ and } G_{M+\frac{1}{2},j+\frac{1}{2}}^{u,x} = \frac{u_{M,j+\frac{1}{2}}}{2} F_{M,j+\frac{1}{2}}.
\]

The fluxes \( G_{u,y}^{i,j} \), for any \((i,j) \in [2,M] \times [2,N]\) are defined by

\[
G_{u,y}^{i,j} = u_{i,j-\frac{1}{2}} F_{i,j}^{y,+} + u_{i,j+\frac{1}{2}} F_{i,j}^{y,-}.
\]

For the boundary values, we set \( G_{u,y}^{i,N+1} = 0 \) and \( G_{u,y}^{i,1} = 0 \) for all \( j \in [2,N] \). Fig. 5 illustrate this construction by putting forward the mass fluxes used in the definition of the momentum flux \( G_{i+\frac{1}{2},j+\frac{1}{2}}^{u,x} \) and \( G_{i,j}^{u,y} \).

Finally, symmetrically, the vertical velocity \( v_{i+\frac{1}{2},j}, \ i \in [1,M], \ j \in [2,N] \) is updated with the following scheme

\[
\frac{\overline{p}_{i+\frac{1}{2},j} - \rho_{i+\frac{1}{2},j} v_{i+\frac{1}{2},j}}{\delta t} + \frac{G_{v,x}^{i+\frac{1}{2},j} - G_{v,x}^{i+1,j}}{\delta x_i} + \frac{\Pi_{i+\frac{1}{2},j} - \Pi_{i+\frac{1}{2},j+\frac{1}{2}}}{\delta y_j} + \frac{G_{v,y}^{i+\frac{1}{2},j} - G_{v,y}^{i+1,j+\frac{1}{2}}}{\delta y_j} = 0. \tag{4.3}
\]
The momentum fluxes \( G^{u,x} \) and \( G^{u,y} \) are defined like \( G^{u,x} \) and \( G^{u,y} \) by inverting the roles played by \( u \) and \( v \), by \( x \) and \( y \), and by \( i \) and \( j \).

\[
\begin{align*}
\frac{F^x_i + \frac{1}{2}}{2} &+ \frac{F^x_i + 1 + \frac{1}{2}}{2} \\
\frac{G^{u,x}_{i+1,j+\frac{1}{2}}}{2} &+ \frac{G^{u,x}_{i+1,j+\frac{1}{2}}}{2} \\
\frac{F^y_{i-j+\frac{1}{2}}}{2} &+ \frac{F^y_{i-j+\frac{1}{2}}}{2} \\
\frac{G^{u,y}_{i,j}}{2} &+ \frac{G^{u,y}_{i,j}}{2}
\end{align*}
\]

(a) Flux \( G^{u,x}_{i+1,j+\frac{1}{2}} \)  
(b) Flux \( G^{u,y}_{i,j} \)

Figure 5: Mass flux used in the definition of momentum fluxes.

It can be shown that under a CFL condition – which can be readily deduced from the 1D statement – the positivity of \( \rho \) is preserved. Similarly, strengthened assumptions can be identified to guaranty that the decay of the global entropy under suitable stability constraints is still valid on MAC meshes, see [4].

We now turn to explain how to extend the second order scheme to the 2D framework. We apply the 1D MUSCL method to the rows or the columns of the physical variables.

- To define the upgraded mass flux \( F^{x,ML} \) we use a MUSCL reconstruction only on the columns of the density \( \rho \) :

\[
F^{x,ML}_{i,j+\frac{1}{2}} = F^+ (\rho^+_{i,j+\frac{1}{2}}, u_{i,j+\frac{1}{2}}) + F^- (\rho^-_{i,j+\frac{1}{2}}, u_{i,j+\frac{1}{2}}).
\]

- To define the upgraded mass flux \( F^{\rho,y,ML} \) we use a MUSCL reconstruction only on the rows of the density \( \rho \).

With this new definition of the mass flux \( F^{x,ML} \) and \( F^{y,ML} \) we define the new convective part of the momentum flux \( G^{u,x,ML} \) and \( G^{u,y,ML} \):

- To define the upgraded momentum flux \( G^{u,x,ML} + p \) we use a MUSCL reconstruction only on the columns of the velocity \( u \) in the convection flux:

\[
G^{u,x,ML}_{i+\frac{1}{2},j+\frac{1}{2}} = \frac{u^-_{i+\frac{1}{2},j+\frac{1}{2}}}{2} \left( \frac{F^{x,ML}+}{i+1,j+\frac{1}{2}} + \frac{F^{x,ML}+}{i,j+\frac{1}{2}} \right) + \frac{u^+_{i+\frac{1}{2},j+\frac{1}{2}}}{2} \left( \frac{F^{x,ML}-}{i+1,j+\frac{1}{2}} + \frac{F^{x,ML}-}{i,j+\frac{1}{2}} \right)
\]

- To define the upgraded mass flux \( G^{u,y,ML} \) we use a MUSCL reconstruction only on the rows of the velocity \( u \).

The stability and consistency analysis performed in 1D generalize directly to higher dimensions on MAC meshes, a configuration which is appealing when dealing with low Mach regimes, see [39, Chapter 3].
5 Numerical simulations

5.1 Barotropic Euler system

5.1.1 Accuracy study using a 1d manufactured solution

In order to numerically validate the abilities of the MUSCL-like approach, we compute the solutions of the 1D problem

$\partial_t \left( \frac{\rho}{\rho u} \right) + \partial_x \left( \frac{\rho u}{\rho u^2 + p(\rho)} \right) = 0$,

where the force field $(x,t) \mapsto f(x,t)$ is tailored so that the solution reads

\[
\begin{align*}
\rho(x,t) &= \rho_0 \frac{x}{x + (1-x)e^t} \frac{e^t}{(x + e^t(1-x))^2}, \\
u(x,t) &= x(1-x).
\end{align*}
\]

To avoid spurious perturbation of the convergence rate by the boundary conditions, we choose $\rho_0(y) = \exp(-50(y-0.5)^2)$. The solution is smooth and we can expect a full benefit of the MUSCL approach. The computational domain is the slab $[0,1]$ and we perform the simulation for $t \in [0,0.18]$. We use zero-flux boundary conditions. In the definition of the fluxes, we make use of the MinMod flux limiter (see (3.6) for the definition). We consider the case where the pressure is defined by the perfect gas state law $p(\rho) = \rho^2$.

We perform several simulations with different number of grid points $J \in \{200, 400, 600, 800, 1200, 1500, 1800\}$ and different time steps $\delta t \in \{4.5e^{-5}, 2.25e^{-5}, 1.5e^{-5}, 1.125e^{-5}, 7.5e^{-6}, 6e^{-6}, 5e^{-6}\}$ while preserving the product $J\delta t$ constant. Further simulations can be found in [39]. On one hand, we use the first order scheme of [5] and on the other hand the MUSCL/RK2 extension proposed in this article. We give in Table 1 the $L^1$-norm of the error between the discrete and exact solutions. The MUSCL/RK2 extension reaches the second order for both the density and the velocity, while, as expected, the scheme of [5] approaches the solution at first order only.

5.1.2 Simulation of 1d Riemann problems

Perfect gases pressure law We now study the behavior of the scheme with discontinuous solutions. We consider Riemann problems on a computational domain $[a,b]$; the initial data is piecewise constant with a jump located at $x = 0$ and we denote by $(\rho_l,u_l)$ and $(\rho_r,u_r)$ the
left and right states for the density/velocity pair, respectively. The pressure law is defined by
\[ p(\rho) = \frac{(\gamma-1)^2}{4\gamma} \rho^\gamma \] with \( \gamma = 1.6 \). We use the MinMod limiter and the others data are given in Table 2.

Table 2: Definition of the test case. Computational domain \([a,b]\). Left and right states for the density and velocity (jump located at \( x = 0 \)).

The corresponding Riemann solutions develop two rarefaction waves, two shocks and a rarefaction wave followed by a shock wave respectively. The results obtained at time \( T=0.5 \) using the first order scheme and the MUSCL/RK2 scheme with \( J=200 \) and \( \delta t=1e^{-3} \) are plotted in Fig 6, Fig 7 and Fig 8. Of course the solutions of Riemann problems are not smooth and the consistency analysis does not apply. Nevertheless, we clearly see that using the MUSCL-like method provides more accurate results than the first order method. (In fact the solution is slightly more diffusive when using the RK2 than with the mere first order Euler time discretization.) The convergence study of the different test cases is presented in Table 3 and we observe a first order convergence.

**Van der Waals pressure law** We check the ability of the scheme in dealing with a more complex pressure law. We set \( p(\rho) = \frac{(\gamma-1)^2}{4\gamma} \left( \frac{\rho^*}{\rho^* - \rho} \right)^\gamma \). This is a particular case of the Van der Waals state law; it arises in the modeling of dusty gases for instance. We point out that this pressure law does not lead to any difficulty in the design of the scheme and its consistency properties apply equally well to this case. Such a pressure law is intended to retain some packing effects that prevent the density to exceed the threshold \( \rho^* \), see Fig 9. Tests are performed with \( \gamma = 2 \) and \( \rho^* = 1 \).

Proposition 5.1 (Close-packing threshold). Suppose that the initial data satisfies $\rho_0^{j+\frac{1}{2}} \leq \rho^*$ for all $j \in [1, J]$ and assume that the following CFL-like condition holds

$$\frac{\delta t}{\delta x_{j+\frac{1}{2}}} \left( \lambda_+ (\rho_j, u_j) \right)^+ + \left( \lambda_- (\rho_{j+1}, u_{j+1}) \right)^- \leq \frac{1}{2} \left( 1 - \frac{\rho_j^{j+\frac{1}{2}}}{\rho^*} \right), \quad \forall j \in [1, J].$$

Then $\rho_{j+\frac{1}{2}} \leq \rho^*$ for all $j \in [1, J]$ and $k \in \mathbb{R}^N$. 

Figure 9: Intermediate volume fraction $\rho_m$ as a function of the velocity $u$. However the preservation of this constraint by the numerical unknown leads to a strengthened stability condition, see [6, Prop. 5]. For the MUSCL version of the scheme the stability condition takes the following form.
Proof. We have
\[ \bar{\rho}_{j+\frac{1}{2}} = \rho_{j+\frac{1}{2}} + \frac{\delta t}{\delta x_{j+\frac{1}{2}}} (F^- (\rho_{j+\frac{1}{2}}^+, u_{j+\frac{1}{2}}) - F^- (\rho_{j+1}^+, u_{j+1})) \]
\[ + \frac{\delta t}{\delta x_{j+\frac{1}{2}}} (F^+ (\rho_{j}^-, u_{j}) - F^+ (\rho_{j+1}^+, u_{j+1})) \]
\[ \leq \rho_{j+\frac{1}{2}} + \frac{\delta t}{\delta x_{j+\frac{1}{2}}} (F^+ (\rho_{j}^-, u_{j}) - F^- (\rho_{j+1}^+, u_{j+1})) \]
\[ \leq \rho_{j+\frac{1}{2}} + \frac{\delta t}{\delta x_{j+\frac{1}{2}}} (\rho_{j}^- [\lambda_+ (\rho_{j}^-, u_{j})]^+ + \rho_{j+1}^- [\lambda_- (\rho_{j+1}^+, u_{j+1})]^+) \).

Let us assume \( \rho_{j+\frac{1}{2}} \leq \rho^* \) for any \( j \); then \( \bar{\rho}_{j} \leq 2\rho^* \) (see the proof of Proposition 3.1). Let us introduce
\[ \epsilon_{j+\frac{1}{2}} = 1 - \frac{\rho_{j+\frac{1}{2}}}{\rho^*} . \]

We get
\[ \bar{\rho}_{j+\frac{1}{2}} \leq \rho^* - \rho^* \left( \epsilon_{j+\frac{1}{2}} - \frac{2\delta t}{\delta x_{j+\frac{1}{2}}} \left( [\lambda_+ (\bar{\rho}_{j}^-, u_{j})]^+ + [\lambda_- (\bar{\rho}_{j+1}^+, u_{j+1})]^+ \right) \right) . \]

Finally, assuming
\[ \epsilon_{j+\frac{1}{2}} \geq \frac{2\delta t}{\delta x_{j+\frac{1}{2}}} \left( [\lambda_+ (\bar{\rho}_{j}^-, u_{j})]^+ + [\lambda_- (\bar{\rho}_{j+1}^+, u_{j+1})]^+ \right) \]
we obtain \( \bar{\rho}_{j+\frac{1}{2}} \leq \rho^* \) for any \( j \).

As observed for the condition ensuring the positivity of the density, the CFL-like condition for the MUSCL scheme is twice more constrained than with the first order scheme. More importantly, this condition is much more demanding than the standard CFL condition since the right-hand side vanishes when the discrete density becomes close to \( \rho^* \). Numerical simulations confirm that such a strengthened condition is actually needed to prevent the density to exceed the threshold \( \rho^* \) when using the scheme proposed in this paper. To illustrate the difficulty, we go back to the numerical tests proposed in [6, Section 4.1]. We perform 1D simulations of the Riemann problem defined by \( \rho_l = \rho_r = \frac{1}{2} \) and \( u_l = u_{abs} \) and \( u_r = -u_{abs} \) for different values of \( u_{abs} \in \{0.5, 0.75, 1, 1.25, 1.5, 1.75, 2, 2.25, 2.5\} \) and different values of the time step \( \delta t \). The larger the velocity \( u_{abs} \) is, the closer to \( \rho^* \) the density \( \rho_m \) in the intermediate state is. The simulations are performed up to the time \( T = 0.1 \) with \( J = 200 \) on the computational domain \([-0.5, 0.5]\) with a discontinuity initially at \( x = 0 \). In Fig. 10 we show the solutions obtained with different schemes: for the same numerical conditions \( \delta t \) and \( \delta x \), the Lax-Friedrichs scheme produces much more numerical diffusion and the solution is poorly captured. In Fig. 11 we zoom on the left part of the density.
Figure 10: Barotropic gas with Van der Waals law: comparison of the kinetic scheme (1st and 2nd order) with the Lax-Friedrichs scheme. Density and Velocity solutions for \( u_{abs} = 2 \).

Figure 11: Barotropic gas with Van der Waals law: comparison of the kinetic schemes (1st and 2nd order with \( J = 200 \)) with the Lax-Friedrichs scheme (\( J = 200 \) and \( J = 800 \)). Zoom on the density solution for \( u_{abs} = 2 \).

For each values of \( u_{abs} \), we select the largest value of \( \delta t \) which yields an “admissible” result (in the sense that it remains oscillation-free at \( T = 0.1 \)). In Fig. 12, we plot this selected \( \delta t \) as a function of \( 1 - \frac{\rho_m}{\rho^*} \). In a logarithm scale, we obtain a straight line with a slope close to 2, which is consistent with Proposition 5.1 since when \( \rho_m \) becomes close to \( \rho^* \), the characteristic speeds behave like \( \left(1 - \frac{\rho_m}{\rho^*}\right)^{-1} \).
Figure 12: Maximal admissible time step $\delta t$ as a function of $1 - \frac{\rho m}{\rho^*}$ in blue; the green line has a slope 1.94.

Note, nevertheless, that the standard CFL is enough to preserve the bounds on the density when using a Godunov or a Lax-Friedrichs scheme. (This latter result uses crucially the convexity of the invariant domain of the PDE, see [11, Section 2.2.1 & Prop. 2.11], and it does not apply when the invariant regions are non-convex, see e.g. [14].) However, the scheme based on the kinetic fluxes is far less diffusive than Lax-Friedrichs’ method, so that it finally competes in terms of numerical effort for a given numerical accuracy.

5.1.3 Numerical simulations in 2d

Falling water columns We turn to 2d simulations, with a test-case inspired from [2]. We simulate three falling columns into a rectangular basin. The computational domain is the two-dimensional square $[-1,1] \times [-1,1]$. We are using the dimensionless Shallow Water system which amounts to set $p(\rho) = \rho^2$, without source terms. The PDE system is endowed with zero flux boundary conditions and the following initial data

$$
\begin{align*}
\rho(0,x,y) &= 3 + \mathbb{1}_{(x-0.5)^2 + (y-0.5)^2 < (0.15)^2} + \mathbb{1}_{(x+0.5)^2 + (y+0.5)^2 < (0.15)^2} + 2 \mathbb{1}_{x^2 + y^2 < (0.2)^2}, \\
u(0,x,y) &= 0, \\
v(0,x,y) &= 0.
\end{align*}
$$

The simulation performed in [2] on a $512 \times 512$ Cartesian mesh is reproduced in Fig. 13: it is based on the second order Nessayhu-Tadmor scheme [41], coupled to a specific reconstruction procedure which is intended to reduce the numerical diffusion and to capture shocks with an enhanced accuracy. The MUSCL scheme competes with such an approach, as it appears in Fig. 14 on the right (simulations have been performed with the MinMod limiter). Fig. 14 shows the advantages in using the MUSCL method compared to the first order scheme, which, for the same numerical parameters, loses the complex structures of the flow. In these simulations, the mesh is a $512 \times 512$ Cartesian mesh, the final time $T = 1.035$ and the time step is $\delta t = 10^{-4}$. As already observed in [2], the simulation is quite sensitive to the time step: some oscillations might appear when $\delta t$ is not small enough.
We also compare the results obtained with the first and second order schemes to a simulation performed with a Spectral Element Method (SEM), stabilized with an entropy viscosity method (EVM), see [42, 43]. We also refer the reader to [40] for further details on this method and the test case which is computed to show the ability of this approach to deal with dry-wet transitions and shocks. The SEM-EVM method is driven by two parameters, $\alpha, \beta$ in the notations of [40]. The color map is identical in Fig. 15 and Fig. 16, but it differs from Fig. 13 and Fig. 14. The left picture shows the result we get when using a first order viscosity everywhere and parameters that imply a $O(h)$ numerical diffusion equivalent to the numerical diffusion of the UpWind scheme (precisely the $(\alpha, \beta)$ pair is $(0.5, \infty)$). The entropy stabilization is strengthened in the right picture (with $(\alpha, \beta) = (1,3)$). The mesh is of size $100 \times 100$ and a fifth order polynomial approximation is used in each quadrangle; this yields 255001 interpolation points in the computational domain whereas our scheme, used for Fig. 16, has 262144 degrees of freedom. In both figures, the results are shown at final time $T = 1.035$, reached with $\delta t = 10^{-4}$. 
Clearly, the result obtained with our first order scheme is smooth and close to the one obtained with the SEM-EVM scheme when adding a first order viscosity. The result obtained with the second order scheme — using the MUSCL procedure — recovers the correct solution (free of spurious oscillations) and is very close to the one obtained with the strengthened EVM stabilization.

Forward facing step This test case is inspired by the standard 2D Mach 3 wind tunnel with a step introduced in [56]. The computational domain $\Omega$ is the L-shaped domain $\Omega = \Omega_0 \setminus \Omega_{\text{step}}$. The computational domain $\Omega$ is the L-shaped domain

$$\Omega = \Omega_0 \setminus \Omega_{\text{step}}, \quad \Omega_0 = [0,3] \times [0,1], \quad \Omega_{\text{step}} = [0.6,3] \times [0,0.2].$$

The rectangle $\Omega_0$ is discretized with a $30\sigma \times 10\sigma$ uniform Cartesian grid ($\sigma \in \mathbb{N}^*$). We take the step into account by removing the mesh points corresponding to the step $\Omega_{\text{step}}$ at the right bottom part of the domain.

The equation of state of the fluid is $p(\rho) = \rho$ and the initial data are given by $\rho = 1$ and $u = (3,0)$. On the top and bottom walls, we use reflection boundary conditions (i.e. zero flux boundary conditions as described in the previous parts of the article). A Dirichlet boundary condition, $\rho = 1$ and $u = (3,0)$, makes the flow enter through the left boundary whereas a free boundary condition is used for the right section. The free boundary condition is implemented

37
by assuming *a priori* that the outgoing flow is supersonic. The mass fluxes at the free boundary are thus defined using (4.1) but with an incoming part set to 0; that is, here, on the right boundary, we set

$$F_{M+1,j+\frac{1}{2}}^e = F^+(\rho_{M+\frac{1}{2},j+\frac{1}{2}}, u_{M+1,j+\frac{1}{2}}).$$

The update of the velocity at the free boundary is performed using (4.2) and (4.3) which now involve momentum fluxes at the exterior the domain (here at the points $\left(x_{M+\frac{1}{2}}, y_{j+\frac{1}{2}}\right)$). These ghost fluxes are defined using a constant extrapolation for the pressure and a linear extrapolation for the outgoing part of the mass fluxes; that is here on the right boundary $\left(x_{M+\frac{1}{2}}, y_{j+\frac{1}{2}}\right)$ (using a uniform mesh), we set

$$u_{M+1,j+\frac{1}{2}} = \frac{3}{2} F_{M+\frac{1}{2},j+\frac{1}{2}}^{x,+} \frac{1}{2} p_{M+\frac{1}{2},j+\frac{1}{2}} + 3 F_{M-\frac{1}{2},j+\frac{1}{2}}^{x,+}.$$

with $F_{M+\frac{1}{2},j+\frac{1}{2}}^{x,+} = F_{M+\frac{1}{2},j+\frac{1}{2}}^{x,+} + \frac{1}{2} F_{M-\frac{1}{2},j+\frac{1}{2}}^{x,+}$.

Fig. 17 presents the results obtained with the first order scheme and the second order scheme (MUSCL/RK2 scheme) on a $900 \times 300$ grid ($\sigma = 30$) with time steps respectively defined by $\delta t = 1/3000$ and $\delta t = 1/6000$. We observe that the structures are sharper with the MUSCL scheme. Cutlines of the density along the lines $y = 0.3$ obtained using the second order scheme on different grids are plotted in Fig. 18. The results are in agreement with the literature [35].

Figure 17: Simulation of the 2d Mach 3 wind tunnel with a step: Density with the first order scheme (up) and with the MUSCL/RK2 scheme (down)
Figure 18: Simulation of the 2D Mach 3 wind tunnel with a step: density cutlines at $y=0.3$ for different grids with the MUSCL/RK2 scheme

5.2 Full Euler system

5.2.1 Accuracy study using a 1d manufactured solution

In order to numerically validate the abilities of the MUSCL-like approach, we compute the solutions of the 1D problem

$$
\partial_t \begin{pmatrix} \rho \\ \rho u \\ \rho e \end{pmatrix} + \partial_x \begin{pmatrix} \rho u^2 + p(\rho, e) \\ \rho u^2/p \\ \rho u e \end{pmatrix} + p(\rho, e) \partial_x \begin{pmatrix} 0 \\ 0 \\ u \end{pmatrix} = \begin{pmatrix} f \\ g \end{pmatrix},
$$

where the force fields $(t,x) \mapsto f(t,x)$ and $(t,x) \mapsto g(t,x)$ are tailored so that the solution reads

$$
\begin{cases}
\rho(t,x) = \rho_0 \left( \frac{x}{x+(1-x)e^t} \right) \frac{e^t}{(x+e^t(1-x))^2}, \\
u(t,x) = x(1-x), \\
p(t,x) = (\gamma-1)\rho_0 \left( \frac{x}{x+(1-x)e^t} \right)^2 e^t(1+x)^2.
\end{cases}
$$

As in Section 5.1, we choose $\rho_0(y) = \exp(-50(y-0.5)^2)$. The solution is smooth and we can expect a full benefit of the MUSCL/RK2 approach. The computational domain is the slab $[0,1]$ and we perform the simulation for $t \in [0,0.18]$ on uniform grids with $\gamma = 1.4$. Tables 4 and 5 gives the $L^1$-norm of the error between the discrete and the exact solutions for several numbers $J \in \{200, 400, 600, 800, 1000, 1200, 1500, 1800\}$ of grid points and several time steps $\delta t \in \{7.2e^{-4}, 3.6e^{-4}, 2.4e^{-4}, 1.8e^{-4}, 1.44e^{-4}, 1.2e^{-4}, 9.6e^{-5}, 8.0e^{-5}\}$. In Table 4, the numerical solution is obtained using the first order scheme in space and a first order Euler scheme in time while in Table 5, the numerical solution is obtained using the second order MUSCL/RK2 scheme. We clearly observe the gain of accuracy with the MUSCL/RK2 scheme. It reaches the second order for both the density, the velocity and the internal energy, while, as expected, the first order scheme approaches the solution at first order only.
Table 4: First order scheme. Error rate in $L^1$-norm between approximate and exact solutions for different numbers of grid points $J$ and time steps $\delta t$.

Table 5: Second order MUSCL/RK2 scheme. Error rate in $L^1$-norm between approximate and exact solutions for different numbers of grid points $J$ and time steps $\delta t$.

5.2.2 Simulation of 1d Riemann problems

We solve numerically some Riemann problems inspired from the classical textbook [50, Section 4.3.3, Chapter 4, pages 129-131] on the computational domain $[0,1]$, see 6. All tests are with $\gamma=1.4$. The simulations are performed 1000 grid points. The time step is given by $\delta t_1=\delta x/100$ for the first order scheme and $\delta t_2=\delta t_1/4$ for the MUSCL scheme. The initial data $\rho$, $u$, $p$ are piecewise constant functions with a discontinuity located at $x_0=0.5$, according to the table below.
In Figures 19 to 23, we represent at the final time $T$ the density $\rho_{j+\frac{1}{2}}$ and the velocity $u_j$ on the first line and the pressure $p_{j+\frac{1}{2}}$ and the internal energy $e_{j+\frac{1}{2}}$ on the second line. The exact solution is in dotted lines and the numerical solutions are given with the solid blue lines for the first order scheme and with the solid red lines for the MUSCL-scheme.

Figure 19: Test 1: the so-called Sod test problem, is a mild test: the solution consists in a left rarefaction, a contact discontinuity and a right shock.
Figure 20: Test 2: the so-called 123 problem, has a solution made of two strong rarefactions and a trivial stationary contact discontinuity.

Figure 21: Test 3: inspired from [56], has a solution made of left rarefaction, a contact discontinuity and a right shock.
Both versions of the scheme produce satisfactory results. As expected, the second order scheme has a reduced numerical diffusion and offers better approximations. Concerning Test #2, we remark that the results obtained for the physical variables $\rho$, $p$ and $u$ is quite satisfactory while the internal energy presents significative discrepancies. According to \cite[Section 6.4, Chapter 6, pages 225-235]{50}, this test is indeed known to be particularly challenging for the internal energy $e$, and even Godunov’s method fails on this problem (and the results in Fig. 19 to Fig. 23 are definitely better than what can be obtained with, say, the Lax-Friedrichs scheme).
In [50], a detailed description of the test cases is given and the performance of several standard numerical methods is commented. Be aware that from [50, Chapter 5] to the end Test 1 is not the same as in [50, Chapter 4], and that Test 5 from [50, Chapter 4] (which is also our Test #5) becomes Test 4 from [50, Chapter 5] to the end. About the overshoot that may be seen in Test #5 and at a lower level in Test #1 and #3, Toro explains in [50, Chapter 6] that it is quite usual, and even unresolved in the case of Test #5. In [50, Section 8.5.5, Chapter 8, pages 282], more details are given about the spurious oscillations and diffusion that appears with most type of resolutions, whereas, similarly to the scheme of Liou and Steffen shown in this part of [50], our scheme sharply solves the fast right shock but at the price of the creation of an overshoot.

5.2.3 Numerical simulations in 2d

This test case is the well-known 2d Mach 3 wind tunnel with a step, introduced in [56]. The computational domain $\Omega$ is the L-shaped domain

$$\Omega = \Omega_0 \setminus \Omega_{\text{step}}, \quad \Omega_0 = [0,3] \times [0,1], \quad \Omega_{\text{step}} = [0.6,3] \times [0,0.2].$$

The rectangle $\Omega_0$ is discretized with a $30\sigma \times 10\sigma$ uniform Cartesian grid ($\sigma \in \mathbb{N}^*$). We take the step into account by removing the mesh points corresponding to the domain $\Omega_{\text{step}}$ at the right bottom part of the domain.

The equation of state of the fluid is $p(\rho, e) = (\gamma - 1) \rho e$ where $\gamma = 1.4$, and the initial data are given by $\rho = 1.4$, $u = (3,0)$ and $p = 1$. On the top and bottom walls, we use reflection boundary conditions which means zero flux boundary conditions as described in the previous parts of the paper). A Dirichlet boundary condition, $\rho = 1.4$ and $u = (3,0)$, makes the flow enter through the left boundary whereas a free boundary condition is used for the right section. The free boundary condition is implemented by assuming a priori that the outgoing flow is supersonic. The mass fluxes at the free boundary are thus defined with an incoming part set to 0; that is, here, on the right boundary, we set

$$u_{M+1,j+1/2} = \frac{3}{2} F_{M+1/2,j+1/2}^x + \frac{1}{2} F_{M-1/2,j+1/2}^x.$$

The update of the velocity at the free boundary is performed by involving momentum fluxes at the exterior the domain (here at the points $(x_{M+1/2,j+1/2})$). These ghost fluxes are defined using a constant extrapolation for the pressure and a linear extrapolation for the outgoing part of the mass fluxes; that is here on the right boundary $(x_{M+1/2,j+1/2})$ (using a uniform mesh)

$$u_{M+1,j+1/2} = \frac{3}{2} F_{M+1/2,j+1/2}^x + \frac{1}{2} F_{M-1/2,j+1/2}^x.$$

We present the results obtained with the first order scheme and the second order scheme on a $960 \times 320$ grid ($\sigma = 32$) with time steps respectively defined by $\delta t = 1/(100\sigma)$ and $\delta t = 1/(400\sigma)$ at time $T = 4$. We observe that the structures are sharper with the MUSCL scheme in Fig. 24 and cutlines of the density along the lines $y = 0.3$ obtained using the first and second order scheme are plotted in Fig. 25.
Figure 24: Simulation of the 2d Mach 3 wind tunnel with a step: Density with the first order scheme (up) and with the MUSCL scheme (down).

Figure 25: Simulation of the 2d Mach 3 wind tunnel with a step: density cutlines at $y=0.3$ for the first (blue) and second (red) order scheme.
