ABSTRACT: Natural Rubber (NR) is a polyisoprene (PI) from renewable resources that exhibits mechanical and thermal properties not accessible with synthetic polyisoprenes (IR). In this article, it was developed a simple route to synthesize new models of NR (PI with a pure microstructure (100% 1,4-*cis*) and two fatty esters linked to the polymer chain-end) in order to clarify the role played by lipids on the “cold crystallization” (CCr) of NR. DSC analysis of this new hybrid polymer revealed that the lipids linked to the backbone were able to crystallize despite of the amorphous matrix, the crystallization temperature being dependent on the length of the linked fatty chain. Furthermore, it was observed that the linked fatty chains prevented PI to crystallize at low temperature (-25°C). Finally, the addition of free fatty acids to the hybrid polymer enhanced the crystallization of the PI chain, more particularly when stearic acid and methyl linoleate were used simultaneously as additives. A

similar investigation was performed with IR (with 97% 1,4- cis and 3% 1,2- units), identical observations could have been made.

FIGURE FOR ToC ABSTRACT

KEYWORDS: Natural Rubber, Elastomers, Functionalization of Polymers, Thermal Properties, Cold Crystallization.

1. Introduction

Natural Rubber (NR) is one of the most important natural polymer as it is widely used in the industry for various applications (tires, gloves, etc...).[¹] It exhibits specific thermo-mechanical properties that cannot be obtained with synthetic polyisoprene (IR) such as strain induced crystallization (SIC), high green-strength, excellent crack resistance and fast cold crystallization (CCr).[²⁻⁵] This later property corresponds to the crystallization of PI at low temperature (usually -25°C) without any external perturbations, contrarily to SIC which implies the deformation of the material.[⁶] The origins of the superior capacities of NR are not yet fully understood despite the wide amount of studies carried out on this topic. Nevertheless, Tanaka *et al.*[⁷⁻¹⁰] showed that it could arise from the structure of the polymer which was described to be composed of a polyisoprene (PI) chain functionalized at one chain-end by a protein and at the other by a phospholipidic moiety (Figure 1). These chain-ends could self-assemble to form a dynamic network in the material thus explaining the superior mechanical properties of NR toward IR.[⁷]

Figure 1: Structure of NR proposed by Tanaka

In 1946, Wood[¹¹] studied the crystallization of NR and showed that the fastest crystallization rate was obtained by keeping the material at -25°C for several hours. Burfield established later that 75% of the final crystallinity could be reached after 3 h of isotherm and that total crystallization was observed after 16 h.[¹²] CCr was shown to be correlated to the suggested structure of NR (Figure 1) and more specifically to the lipidic chain-end. The influence of free

fatty acid/esters present in NR was also investigated as well as their interaction with the PI chain.^[13–20] Kawahara *et al.* demonstrated that saturated fatty acids/esters (stearic acid being the main studied) enhanced the crystallization of NR and that unsaturated ones (methyl linoleate for example) had a plasticizing effect on the PI chain.^[16] Regardless the nature of the fatty acid, it was shown a synergetic effect between linked and free fatty chains as well as between stearic acid and methyl linoleate to promote the cold crystallization of the material.^[19,21] Similar studies were also performed on synthetic polyisoprenes. To this end, lipids were grafted onto IR by hydroboration using the pendant 3,4-units, leading to a model of NR.^[20] A fast crystallization was observed when the backbone was functionalized with 0.5 wt % of stearic acid and mixed with 1 wt % of methyl linoleate, but even if it was faster than the starting IR, it was still slower than NR. This difference could be related to the microstructure of NR, which is commonly accepted to be pure 1,4-*cis* contrarily to the IR used by Kawahara which contained about 2 % of 1,2 and 3,4 units.^[22]

In this study, it was investigated the synthesis of new hybrid polymers formed from the functionalization of a pure 1,4-*cis* PI (molar mass of ~10 000 g/mol) with one or two fatty chains at one chain-end as a closer model of NR and their cold crystallization properties. Even if isoprene polymerization was already studied by many techniques (cationic,^[23,24] anionic,^[25] radical,^[26–28] metathesis,^[29] and coordination polymerization^[30]), none of them allowed to reach a pure 1,4-*cis* microstructure with controlled chain-ends.

Oxidative degradation of NR by successive epoxidation and acidic degradation was preferred as it could lead to pure 1,4-*cis* PI with controlled molar mass and ketone and aldehyde reactive chain-ends.^[31] Reactive chain-ends could then be easily modified to graft lipidic moieties. The general synthetic strategy developed in this study is depicted on Figure 2. In this paper, the influence of the nature of fatty acids on the crystallization properties will be discussed as well as the influence of the addition of free lipids. Finally, modification of a

synthetic polyisoprene will also be studied to try to mimic the crystallization properties of NR.

2. Experimental Section

2.1. Materials

Natural rubber (NR) RRIM600 was kindly provided by Katsetsart University in Thailand. *Cis*-1,4-polyisoprene (IR) (97% *cis*-1,4, $M_n = 600$ kg/mol, $\bar{D} = 2.8$) was purchased from Scientific Polymer Products, Inc. 3-chloroperoxybenzoic acid (*m*-CPBA) (70-75%, Acros), periodic acid (H_5IO_6) ($\geq 99\%$, Aldrich), acetic acid (99%, Aldrich), potassium hydroxide (KOH) (85%, Aldrich), sodium triacetoxyborohydride ($\text{NaBH}(\text{OAc})_3$) (97%, Aldrich), diethanolamine (DEA) (99%, Alfa Aesar), stearic acid (SA) (95%, Aldrich), myristic acid (MA) (99%, Aldrich), lignoceric acid (LA) ($> 99\%$, Aldrich), methyl linoleate (ML) (99%, Aldrich), linoleoyl chloride ($>99\%$, Aldrich), 10-undecenoyl chloride (97%, Aldrich),

palmitoyl chloride (98%, Aldrich), 3-aminopropyl-functionalized silica gel (~1 mmol/g NH₂ loading, 40-63µm, Aldrich), oxalyl chloride (>99%, Aldrich) were used without further purification. Tetrahydrofuran (THF) and dichloromethane (DCM) were dried on alumina column. Triethylamine (TEA) was dried on KOH pellets and distilled prior to use. Methanol, diethyl ether, dimethylformamide (DMF) (reagent grade, Aldrich) as well as Celite® (R566, Aldrich) were used as received.

2.2. Characterization

Liquid-state 2D NMR, ¹H NMR and ¹³C NMR spectra were recorded at 298 K on a Bruker Avance 400 spectrometer operating at 400 MHz and 100 MHz respectively in appropriate deuterated solvents. Polymer molar masses were determined by Size Exclusion Chromatography (SEC) using tetrahydrofuran as the eluent (THF with 250 ppm of Butylated hydroxytoluene as inhibitor, Aldrich). Measurements were performed on a Waters pump equipped with Waters RI detector and Wyatt Light Scattering detector. The separation is achieved on three Tosoh TSK gel columns (300 × 7.8 mm) G5000 HXL, G6000 HXL and a Multipore HXL with an exclusion limits from 500 to 40 000 000 g/mol, at a flow rate of 1 mL/min. The injected volume was 100 µL. Columns' temperature was 40 °C. M_n and Đ values were calculated using $dn/dc(\text{polyisoprene})=0.130$. Data were processed with Astra software from Wyatt. Differential scanning calorimetry (DSC) measurements were performed using a DSC Q100 LN₂ or a DSC Q100 RSC apparatus from TA Instruments depending on the experiment. With DSC Q100 LN₂, the samples were first heated to 80°C during 20 minutes to suppress any trace of solvent then cooled to -100°C and heated back to 120°C at a rate of 10°C min⁻¹. Consecutive cooling and heating run were also performed at 10°C min⁻¹. The analyses were carried out in a helium atmosphere with aluminum pans. DSC Q100 RSC device was used for isothermal analysis. The samples were heated at 80°C during 20 minutes

prior to use to suppress any trace of solvent, then cooled to -25°C during predetermined time and then heated to 120°C at a heating rate of $10^{\circ}\text{C min}^{-1}$. Fourier Transformed Infra-Red-Attenuated Total Reflection (FTIR-ATR) spectra were recorded between 4000 and 400 cm^{-1} on a Bruker VERTEX 70 instrument (4 cm^{-1} resolution, 32 scans, DLaTGS MIR) equipped with a Pike GladiATR plate (diamond crystal) for attenuated total reflectance (ATR) at room temperature.

2.3. Synthesis

2.3.1. Synthesis of heterotelechelic keto-aldehyde PI (**PIDeg**) (**1**).

NR (5 g) was dissolved overnight in 250 mL of THF under vigorous stirring. The viscous solution obtained was then cooled to 0°C and 50 mL of mCPBA (0.14 g, 0.6 mmol) solution in THF were added dropwise to the NR solution. The reaction was then allowed to warm up to room temperature for 2 h. Periodic acid (0.3 g, 2.2 eq compared to m-CPBA, 1.33 mmol) were dissolved in 50 mL of THF and added dropwise to the epoxidized NR solution. After 2 h of stirring at room temperature, the reaction mixture was filtered affording a yellow solution which was then concentrated in vacuum and precipitated into a large excess of cold methanol containing 2 mL of alkaline water. The polymer was then dissolved in diethyl ether (~ 100 mL) and the obtained cloudy solution was filtered on Celite[®]. The final product was obtained by evaporation of the Et_2O and drying overnight at 40°C under dynamic vacuum affording a yellowish and transparent viscous liquid. *Yield*: $\sim 80\%$, $M_n = 9\,620\text{ g/mol}$, $\bar{D} = 1.6$ (Figure S1). ^1H NMR (CDCl_3 , Figure S2) δ (ppm): 9.77 (t, $1\text{H}_{\text{chain-end}}$, CH_2CHO), 5.13 (t, 1H $\text{CH}=\text{CCH}_3$), 2.49 (t, 2H , CH_2CHO), 2.44 (t, 2H , CH_2COCH_3), 2.35 (t, 2H , $\text{CH}_2\text{CH}_2\text{CHO}$), 2.13 (s, 3H , CH_3COCH_2), 2.05 (s, 4H , $\text{CH}_2\text{CH}/\text{CH}_2\text{CCH}_3$), 1.68 (s, CH_3CCH). FTIR (Figure

S3): $\nu_{\text{H-C=C}}$: 3035 cm^{-1} ; $\nu_{\text{CH}_2, \text{CH}_3}$: 2900–2730 cm^{-1} ; $\nu_{\text{C=O}}$: 1722 cm^{-1} ; $\delta_{\text{C=C}}$: 1664 cm^{-1} ; $\nu_{\text{CH}_2\text{CH}_3 \text{ cis-1,4-}}$: 1446, 1375 cm^{-1} ; $\delta_{\text{C=C-H}}$: 833 cm^{-1}

2.3.2. Synthesis of heterotelechelic keto-diol PI (**PIDiOH**) (2).

PIDeg (3.7 g, 0.37 mmol of aldehyde groups) was dissolved in 10 mL of dry THF. Diethanolamine (0.19 g, 4.5 eq, 1.66 mmol) was added and the reaction was stirred at 40°C for 2 h. Finally, sodium triacetoxyborohydride (0.36 g, 4.2 eq, 1.55 mmol) was added to the reaction mixture followed by acetic acid (30 μL , 1.3 eq, 0.48 mmol). The heterogeneous medium was stirred at 40°C overnight. The reaction mixture was then directly precipitated into a large excess of cold methanol under vigorous stirring. The polymer was further dissolved in DCM and precipitated again in cold methanol, dissolved in Et_2O , filtered on Celite® and dried under vacuum at 40 °C overnight affording a colorless viscous liquid. Yield: ~ 85 %. ^1H NMR (CD_2Cl_2 , Figure S5) δ (ppm): 5.14 (s, 1H, $\text{CH}=\text{CCH}_3$), 3.57 (t, 4H, $(\text{CH}_2)_2\text{OH}$), 2.64 (t, 4H, $\text{N}(\text{CH}_2)_2$), 2.52 (t, 2H, CH_2N), 2.42 (t, 2H, CH_2COCH_3), 2.05 (s, 4H, $\text{CH}_2\text{CH} / \text{CH}_2\text{CCH}_3$), 1.67 (s, 3H, CH_3CCH)

2.3.3. Synthesis of heterotelechelic keto-hydroxyl PI (**PIOH**) (3).

PIDeg (2 g, 0.2 mmol of aldehyde groups) was dissolved in 5 mL of dry THF. Triacetoxyborohydride (0.19 g, 4 eq, 0.8 mmol) as well as acetic acid (12 μL , 1 eq, 0.2 mmol) were then added. The reaction mixture was stirred at 40 °C overnight and the final product was obtained after two successive precipitations into a large excess of cold methanol, dissolution in Et_2O , filtration through Celite® and drying overnight at 40°C under dynamic vacuum. The PIOH is a viscous and colorless liquid. Yield: ~ 90 %. ^1H NMR (CDCl_3 , Figure S12) δ (ppm): 5.12 (t, 1H, $\text{CH}=\text{CCH}_3$), 3.62 (t, 2H, CH_2OH), 2.42 (t, 2H, CH_2COCH_3), 2.05 (s, 4H, $\text{CH}_2\text{CH} / \text{CH}_2\text{CCH}_3$), 1.67 (s, 3H, CH_3CCH)

2.3.4. Synthesis of fatty acyl chlorides (**C_{14:0}Chlo** / **C_{18:0}Chlo** / **C_{24:0}Chlo**).

A solution of the desired fatty acid was prepared in dry DCM ([fatty acid] = 0.5M). Oxalyl chloride (3 eq) was then added to the mixture under vigorous stirring followed by 3 drops of DMF. A vigorous bubbling was observed. The reaction conversion was followed by connecting the reaction flask to a bubbler containing a KOH solution. When bubbling was no more visible, the reaction mixture was evaporated under vacuum to remove the solvent and the excess of oxalyl chloride. The final product was then dried overnight at 40°C under dynamic vacuum affording a yellowish liquid for **C_{18:0}Chlo** and **C_{14:0}Chlo** and a white powder for **C_{24:0}Chlo**. *Yield*: > 90 %.

C_{14:0}Chlo: ¹H NMR (CDCl₃, Figure S7) δ (ppm): 2.87 (t, 2H, CH₂CCl), 1.70 (m, 2H, CH₂CH₂Cl), 1.25 (s, 20H, (CH₂)₁₀), 0.88 (t, 3H, CH₃CH₂); ¹³C NMR (CDCl₃, Figure S8) δ (ppm): 174.21 (1C, COCl), 47.28 (1C, COCH₂), 31.93 (1C, COCH₂CH₂), [29.65, 29.64, 29.61, 29.52, 29.36, 29.33, 29.07, 28.43, 25.07, 22.71] (10C, CH₂-fatty chain), 14.11 (1C, CH₂CH₃). **C_{18:0}Chlo**: ¹H NMR, (CDCl₃, Figure S7) δ (ppm): 2.87 (t, 2H, CH₂CCl), 1.70 (m, 2H, CH₂CH₂Cl), 1.25 (s, 28H, CH₂, fatty chain), 0.88 (t, 3H, CH₃CH₂); ¹³C NMR (CDCl₃, Figure S8) δ (ppm): 174.21 (1C, COCl), 47.28 (1C, COCH₂), 31.93 (1C, COCH₂CH₂), [29.81, 29.75, 29.66, 29.52, 29.46, 29.21, 28.57, 25.20, 22.83] (14C, CH₂-fatty chain), 14.25 (1C, CH₂CH₃). **C_{24:0}Chlo**: ¹H NMR, (CDCl₃, Figure S7) δ (ppm): 2.87 (t, 2H, CH₂CCl), 1.70 (m, 2H, CH₂CH₂Cl), 1.25 (s, 40H, CH₂, fatty chain), 0.88 (t, 3H, CH₃CH₂); ¹³C NMR (CDCl₃, Figure S8) δ (ppm): 174.21 (1C, COCl), 47.28 (1C, COCH₂), 31.93 (1C, COCH₂CH₂), [29.86, 29.76, 29.68, 29.52, 29.49, 29.22, 28.59, 25.21, 22.86] (20C, CH₂-fatty chain), 14.28 (1C, CH₂CH₃).

2.3.5. Synthesis of heterotelechelic keto-dilipid PI (**PIDiLip**) (4).

PIDiOH (2 g, 0.2 mmol of hydroxyl groups) was dissolved in 7 mL of dry THF. TEA (180 μ L, 6 eq, 1.2 mmol) was then added followed by the desired acyl chloride (3 eq, 0.6 mmol). After 1 h of reaction, 3-aminopropyl-functionalized silica particles were added (~ 1 NH₂ eq toward acyl chloride) and the mixture was stirred for 2 h. The reaction medium was then precipitated in a large excess of cold methanol, dissolved in Et₂O, filtered through Celite[®] and dried first on rotary evaporator and then overnight at 40°C under vacuum. The final compound was a colorless viscous liquid except for PIDiC_{24:0} which was a colorless paste. *Yield*: ~ 80 %. ¹H NMR (CD₂Cl₂, Figure S9) δ (ppm): 5.12 (s, 1H, CH=CCH₃), 4.09 (t, 4H, (CH₂)₂OCO), 2.74 (t, 4H, N(CH₂)₂), 2.51 (t, 2H, CH₂N), 2.43 (t, 2H, CH₂CCH₃), 2.26 (t, 4H, OCOCH₂) 2.05 (s, 4H, CH₂CH / CH₂CCH₃), 1.67 (s, 3H, CH₃CCH), 1.26 (s, CH₂, fatty chain), 0.88 (t, 6H, CH₂CH₃).

2.3.6. Synthesis of heterotelechelic keto-monolipid PI (**PImonoLip**) (5).

PIOH (1 g, 0.1 mmol of hydroxyl groups) was dissolved in 4 mL of dry THF. TEA (60 μ L, 4 eq, 0.4 mmol) was added followed by the desired acyl chloride (2 eq, 0.2 mmol). After 1 h of reaction, 3-aminopropyl-functionalized silica particles were added (~ 1 NH₂ eq toward acyl chloride) and the obtained mixture was stirred for 2 h. The final polymer was obtained after two successive precipitations into a large excess of cold methanol, dissolving in Et₂O, filtration through Celite[®] and overnight drying at 40°C under dynamic vacuum. *Yield*: ~ 80 %. ¹H NMR (CDCl₃, Figure S13) δ (ppm): 5.12 (s, 1H, CH=CCH₃), 4.03 (t, 2H, CH₂OCO), 2.43 (t, 2H, CH₂CCH₃), 2.26 (t, 2H, OCOCH₂) 2.05 (s, 4H, CH₂CH / CH₂CCH₃), 1.67 (s, 3H, CH₃CCH), 1.26 (s, CH₂, fatty chain), 0.88 (t, 3H, CH₂CH₃).

3. Results and Discussion

3.1. Polymer modification.

3.1.1. Synthesis of PIDeg (1)

The epoxidation and the acidic degradation (Figure 2) were performed successively without intermediate purification. During the precipitation step in methanol, the use of alkaline water was compulsory to prevent acetal formation at the aldehyde chain-end. In this study, 10 000 g/mol PIDeg was targeted.

The targeted molar mass can be adjusted by using the following formula:

$$\begin{aligned} \dot{M}_n &= \frac{100 \cdot 68}{T_x} + 100 \\ T_x &= \frac{[\text{epoxidized units}]}{[\text{monomer units}]} * 100 \% \dot{M}_n : \text{Targeted molar mass (g/mol)} \end{aligned}$$

The progress of the degradation reaction was monitored by SEC, ¹H NMR, 2D NMR and FTIR-ATR analyses (Figures S1 to S4). By SEC, it was observed a decrease of the molar mass from 500 000 g/mol (NR) to 10 000 g/mol (PIDeg) as well as a decrease of the molar mass distribution from 2.6 (NR) to 1.6 (PIDeg). The formation of carbonyl chain-ends was confirmed by ¹H NMR with the appearance of a triplet at 9.77 ppm characteristic of the aldehyde proton as well as the appearance of 3 triplets at 2.49, 2.44 and 2.35 ppm corresponding to “CH₂” groups in α and β position of the aldehyde and in α position of ketone chain-end respectively. Moreover, the appearance of a band at 1722 cm⁻¹ in FTIR-ATR also confirmed the generation of carbonyl functions.

3.1.2. Synthesis of PIDiLip (4)

For the synthesis of PIDiLip (4), the reductive amination of the aldehyde chain-end of **(1)** with diethanolamine and NaBH(OAc)₃ was first performed to yield PIDiOH **(2)**. Compared to the procedure described in the literature^[32], the solvent was changed, THF instead of

DMSO/dichloroethane mixture, giving a higher reaction rate. ^1H NMR analysis (Figure S5) showed a quantitative conversion with the total disappearance of the signals at 9.77, 2.49 and 2.35 ppm corresponding to the aldehydic proton and both “CH₂” groups in α and β position of the aldehyde chain-end respectively. Furthermore, the appearance of signals at 3.57, 2.64 and 2.52 ppm corresponding to both “CH₂” groups in α and β position of the hydroxyl function and to the “CH₂” group in α position of the nitrogen atom respectively also confirmed the good control of the reaction. Finally, the selectivity was confirmed by the presence of the signal at 2.43 ppm corresponding to the “CH₂” group in α position of the ketone chain-end. It was confirmed by 2D NMR analysis (Figure S6). The following step was to add two fatty chains at the DiOH chain-end through acylation reactions affording **(4)**. The corresponding fatty acyl chlorides were first synthesized through the reaction of fatty acids with oxalyl chloride in dichloromethane with excellent yields (Figures S7 and S8). As confirmed by the total shift of the signal at 2.35 ppm in ^1H NMR corresponding to the “CH₂” group in α position of the carboxylic acid carbonyl to a signal at 2.87 ppm after the chlorination. Moreover, on ^{13}C NMR spectrum, the shift of the signal at 182 ppm corresponding to the carbon of the carboxylic acid carbonyl to a signal at 174.21 ppm after chlorination also confirms the full conversion. These acyl chlorides were then reacted with **(2)** in dry THF in the presence of triethylamine. Again, ^1H NMR analysis (Figures S9 and S10) confirmed full conversion with the total shift of the signal at 3.57 ppm corresponding to the “CH₂” group in α position of the hydroxyl chain-end to a new signal at 4.09 ppm corresponding to the “CH₂” group in α position of the formed ester. 2D NMR also confirmed the full conversion (Figure S11). The use of the silica beads functionalized by amino-propyl groups is important as it prevents contamination of the product by di-ketene (side product) formed during the reaction^[33] and removes the excess of unreacted acyl chloride. No change on the SEC

chromatogram was observed, attesting that no cross-linking occurred during the overall pathway.

3.1.3. Synthesis of PIMonoLip (5)

For the synthesis of PIMonoLip (5), aldehyde chain-end of PIDeg (1) was first selectively reduced with $\text{NaBH}(\text{OAc})_3$, a reducing agent known for its selectivity toward aldehydes against ketone,^[34] to yield PIOH (3). ^1H NMR analysis (Figure S12) confirmed the quantitative conversion with the disappearance of the signals at 9.77, 2.49 and 2.35 from (1) corresponding to the aldehydic proton and both “CH₂” groups in α and β position of the aldehyde chain-end respectively. A new signal appeared at 3.62 ppm corresponding to the signal of the “CH₂” group in α position of the newly formed hydroxyl function. The last step was the addition of one fatty chain via an esterification reaction similarly to the synthesis of (4). Again, the reaction was carried out in dry THF using fatty acyl chlorides and triethylamine as a proton trap. The ^1H NMR analysis (Figure S13) showed a quantitative conversion with the total shift of the signal at 3.62 ppm corresponding to the “CH₂” group in α position of the hydroxyl chain-end to a signal at 4.03 ppm corresponding to the same group in α position of the new ester function. No change in the SEC chromatogram was observed attesting that no side reaction occurred.

3.2. Thermal analysis of the hybrid polymers synthesized

First, regular DSC analyses of the PIDiLip were performed. Figure 3 shows the DSC thermogram obtained for PIDiC_{18:0}. It can be observed a T_g at -63°C as well as a crystallization (and a melting) at low temperature for the hybrid polymer, whereas for NR, PIDeg and PIDiOH (Figures S14 to S16), only a T_g at -63°C was observed. This could not be due to PI crystallization which was reported to be slow, occurring only while maintaining the rubber at

low temperature (usually -25°C) for a long time. It can then be assumed that the lipids linked at the chain-ends could crystallize. Furthermore, it was possible to tune the crystallization and melting temperature of the chain-ends by varying the nature of the fatty acid as indicated on Table 1. Indeed, T_m and T_c increased with the fatty acid chain length (Figures S17 to S22). For instance, T_m increased from -25 to 22°C for $\text{C}_{16:0}$ and $\text{C}_{24:0}$ respectively.

Nevertheless, for unsaturated fatty acids ($\text{C}_{11:1}$ and $\text{C}_{18:2}$) and smaller saturated fatty acid ($\text{C}_{14:0}$), no crystallization occurred. For $\text{PIDiC}_{24:0}$, as the melting temperature is close to room temperature, the material became more viscous due to partial crystallization. In the case of PIMonoLip , only $\text{PIMonoC}_{24:0}$ presented a crystallization but at a temperature much lower than $\text{PIDiC}_{24:0}$ (-35°C instead of 17°C). This suggests that the number of chains grafted to the polymer backbone is also an important parameter for the chain-end crystallization.

Figure 3: DSC thermogram of $\text{PIDiC}_{18:0}$

Table 1. Crystallization and melting temperatures of various PiDiLip observed by DSC

Grafted fatty acid	T_m ^{a)}	T_c ^{b)}
	($^{\circ}\text{C}$)	($^{\circ}\text{C}$)
Undecenoic acid ($\text{C}_{11:1}$)	- ^{c)}	- ^{c)}

Linoleic acid (C18:2)	- ^{c)}	- ^{c)}
Myristic acid (C14:0)	- ^{c)}	- ^{c)}
Palmitic acid (C16:0)	-25	-37
Stearic acid (C18:0)	-11	-18
Nonadecanoic acid (C19:0)	-5	-13
Lignoceric acid (C24:0)	22	17

^{a)} Melting temperature observed by DSC; ^{b)} Crystallization temperature observed by DSC; ^{c)}

No crystallization or melting observed by DSC

In a second step, as PIDiLip were thought to be simple models of NR, it was decided to study their cold crystallization behavior. DSC analysis was used to study the crystallization of the starting NR after 2 and 8 h of isotherm at -25 °C (Erreur : source de la référence non trouvée).

Figure 4: DSC thermograms of NR obtained after 2h and 8h at -25°C

It can be seen, as reported in the literature, that the crystallization process is quite long as only a small melting endotherm can be observed after 2 h at -25 °C. Interestingly, exothermal crystallization peak can be observed during the isotherm as a function of time (Figure 5). It was defined in the literature different characteristic times: t_i (induction time, corresponding to the starting time of isothermal analysis), t_m (time of maximum crystallization, *i.e* the time at which the maximum of the plot is observed) and t_e (extrapolated time, *i.e* the time at which the crystallization is effectively starting). A fourth value was added, t_f , corresponding to the

time at which the crystallization is finished (see Figure 5 line b). Similar analyses were then achieved for PIDeg and PIDiOH (Figure 5).

Figure 5: DSC thermograms obtained for 8 h isothermal crystallization at -25°C of NR, PIDiOH and PIDeg

All the characteristic times are summarized in as well as the melting temperatures obtained for each sample by performing DSC heating cycle following isothermal crystallization. For PIDiOH and PIDeg, the crystallization started with a delay (t_e : 93 and 82 min for PIDeg and PIDiOH respectively) but maximum of heat flow was achieved after similar crystallization time for all three polymers ($t_m - t_e \approx 150$), as well as crystallization finished in ~ 320 min ($t_f - t_e$) in all three cases. In the literature, such a delay was only observed for acetone extracted NR (AE-NR) (removal of the free fatty chains by acetone extraction) or trans-esterified NR (TE-NR) (removal of both linked and free fatty chains). In our case, it could thus mean that controlled degradation removed free and/or linked fatty chains from the initial NR but that the reductive amination had no effect. Finally, an increase of the overall crystallinity of the PIDeg and PIDiOH was observed compared to the initial NR (higher enthalpy), which is in agreement with the literature^[21], as Kawahara reported a delayed crystallization of TE-NR compared to NR but a higher final crystallinity.

Table 2. Characteristic values of CCr of NR, PIDeg and PIDiOH obtained for 8 h isothermal crystallization at - 25°C

Sample	$t_i^{a)}$	$t_e^{a)}$	$t_m^{a)}$	$t_f^{a)}$	$\Delta H_m^{b)}$	$T_m^{c)}$
	(min)	(min)	(min)	(min)	(J/g)	(°C)
NR (RRIM 600)	0	0	146	338	14	-1
PIDeg	0	93	249	408	23	-1
PIDiOH	0	82	236	396	21	0

^{a)} Characteristic times obtained from the DSC thermograms; ^{b)} Melting enthalpy calculated from the area of the melting endotherm on the DSC thermograms. ^{c)} Melting temperatures obtained from the DSC thermograms

The cold crystallization of PIDiC_{18:0} was then investigated and compared to the one of PIDiOH (Figure 6). Endotherm peaks were visible in both cases. Nevertheless, in the case of PIDiOH, the observed endotherm corresponded to the melting of the crystallized PI chains, whereas for PIDiC_{18:0}, the endotherm was due to the melting of the chain-ends as the melting temperature is lower than the one of PI chains and corresponds to the T_m of the chain-ends during regular DSC cycle (Figure 3, Table 2). The grafted fatty chains at one chain-end seemed then to prevent (or at least significantly decrease) the CCr of the polymeric chains. This observation is in good agreement with the literature as AE-NR (only containing linked lipids) presented a huge decrease in the crystallization rate.

The effect of the number of linked fatty chains was also investigated. In the case of PIMonoLip, no PI crystallization was observed (Figure S23). Tanaka suggested that grafting fatty chains onto PI decreases the “purity” of the sample thus rendering the crystallization less favorable.^[14] In our case, the absence of crystallization of PI even after 8 h of isotherm can be related to the mass fraction of lipids which acted as a huge quantity of “impurities” in the case of PIDiC_{18:0} (5.7 wt %).

Figure 6: DSC thermograms of a PIDiC_{18:0} and PIDiOH after 8 h of isothermal crystallization at -25 °C

In a last step, free lipids were added to try to recover a cold crystallization for the hybrid material. Indeed, methyl linoleate (ML) and stearic acid (SA), which represent the major part of the lipids in the *Hevea* NR^[35], were reported to have a nucleating effect for SA and a plasticizing effect for ML on the CCr of NR. PIDiC_{18:0} was investigated first and was mixed with 4 % SA, 4 % ML and 4 % ML + 4 % SA (wt%). DSC thermograms are given on Figure 7. The addition of 4 % of ML did not induce any crystallization of the polymer and only the melting of the lipidic chain-ends was present. On the contrary, the addition of 4 % SA or 4 % ML + 4 % SA favored CCr of the PI chains with a higher melting enthalpy when both free lipids were added, showing the synergetic effect of SA and ML. Moreover, the melting of SA can be observed at 48°C. Nevertheless, even in the presence of 4 % of both SA and ML, the overall crystallinity was much lower than that of NR. This is a different behavior than AE-NR for which addition of SA with ML allowed to recover the original crystallinity^[19,20]. This can be due to a much higher weight content of linked fatty chains in our case as well as the low molar mass used for this study (~10 000 g/mol).

Figure 7: DSC thermograms of PIDiOH, PIDiC_{18:0} and PIDiC_{18:0} mixed with various amount of ML and SA after isothermal crystallization at -25°C for 8h

By mixing PIDiOH with 4 % of SA + 4 % of ML, it can be seen on Figure 8 that the addition of free fatty chains increased the crystallization rate which became even higher than the one of NR (t_m and t_f of 91 and 182 min vs 146 and 338 min respectively) with an overall crystallinity comparable to the one of PIDiOH reported in

. It can be assumed that the nucleating effect of SA created the first nodules of crystallization and that the plasticizing capacity of ML conferred mobility to the chains even at low temperature.

Figure 8: Isothermal crystallization study of a PiDiOH alone and with 4 % ML + 4 % SA after isothermal crystallization at -25 °C for 8 h

A similar study was also performed with a high molar mass IR ($M_n \sim 600\,000$ g/mol) having high content of 1,4-*cis* units ($\sim 97\%$). The same chemical procedures were followed to synthesize again hybrid polymer (IRDiC_{18:0}) with a molar mass of polyisoprene of 10 000 g/mol. The chain-end crystallization occurred like for PiDiC_{18:0} synthesized from NR (Figure S24). Nevertheless, contrarily to NR, no crystallization was observed for the IRDiOH (Figure S25), neither for the starting IR maintained at -25°C for 8h. The time of isotherm was thus extended to 60 h and in this case crystallization appeared only for the initial IR (Figure S26) but not for IRDeg (Figure S27). These results suggest that the CCr of IR is much slower than the one of NR certainly due to the presence of 1,2- and 3,4-units in the microstructure but also that the higher the molar mass, the quicker the CCr. As expected, IRDiC_{18:0} did not exhibit any crystallization in agreement with the absence of CCr for IRDeg. IRDeg and IRDiC_{18:0} were then mixed with free lipids (4 % ML + 4 % SA) and maintained at -25°C for 60 h. The DSC thermograms obtained are reported in Figure 9. Both the IRDiC_{18:0} and the IRDeg recovered a CCr. In the case of the hybrid, only a weak endotherm can be observed which is partially covered by the melting of the fatty chain-end. But, like in the case of PiDeg mixed with free lipids, the IRDeg exhibits a huge endotherm corresponding to the crystallization of

the PI. Moreover, the size of the endotherm obtained in the case of IRDeg mixed with free lipids is even bigger than the one of the starting IR. Again, this confirms the boosting role of the free lipids for the crystallization of PI.

Figure 9: DSC thermograms of a high molar mass IR, IRDeg mixed with free fatty chains and IRDiC_{18:0} also mixed with free fatty chains. Obtained after 60 h of crystallization at -25 °C.

4. Conclusion

In this study, several hybrid polyisoprenes ($M_n \approx 10\,000$ g/mol) bearing one or two fatty chains at one chain-end were synthesized either from NR (100 % 1,4-*cis* units) or from IR (97 % 1,4-*cis* units) as models of NR. Before the grafting of the fatty chain, polymers coming from NR exhibited a high crystallinity after isothermal treatment at -25°C, whereas polymers coming from IR showed no crystallinity probably due to the presence of other units than 1,4-*cis*. Detailed DSC analyses of the hybrid polymers showed that the grafting of lipidic chains prevented cold crystallization of polyisoprene, a general feature of NR. On the contrary, chain-ends could crystallize relatively quickly despite the huge amorphous matrix. The addition of free fatty acids to the hybrid polymer allowed to recover a partial cold crystallization in a lower amount than the initial NR. Nevertheless, addition of both SA and

ML presented a synergetic effect to enhance CCr of all the polymers either natural or synthetic. All these observations allow to clarify the role of both free and linked fatty chains on the CCr of NR and allowed to obtain a crystallization rate of a 10 000 g/mol IR comparable to the one of a 600 000 g/mol IR.

These results open new perspectives for synthetic chemists as it seems to be possible to synthesize elastomers of low molar mass that could mimic the properties of NR (of very high molar mass) that are generally far to be reached by regular synthetic elastomers.
