Abstract—To ease spectral congestion and enhance frequency reuse, researchers are targeting smart antenna systems using spatial multiplexing and adaptive signal processing techniques. Moreover, the accuracy and efficiency of such systems is highly dependent on the adaptive algorithms they employ. A popular, adaptive beamforming algorithm, widely used in smart antennas, is the Recursive Least Square (RLS) algorithm. While, the classical RLS implementation achieves high convergence, it still suffers from its inability to track the target of interest. Recently, a new adaptive algorithm called Recursive Least Square - Least Mean Square (RLMS) which employs a RLS stage followed by a Least Mean Square (LMS) algorithm stage and separated by an estimate of the array image vector, i.e. steering vector, has been proposed. RLMS outperforms previous RLS and LMS variants, with superior convergence and tracking capabilities, at the cost of a moderate increase in computational complexity. In this paper, an enhanced, low complexity parallel version of the cascade RLMS is presented by eliminating the need for computing the array image vector cascading stage. Hence, For an antenna of N elements our strategy can reduce the complexity of the system by $20N$ multiplications, $6N$ additions and $2N$ divisions. Moreover, a new Kalman based parallel RLMS (RKLMS) method is also proposed, where the LMS stage is replaced by a Kalman implementation of the classical LMS, and compared under low Signal to Interference plus Noise ratios (SINR). Simulation results show identical performance for the parallel RLMS, cascaded RLMS at 10dB and superior performance and robustness for the RKLMS on low SINR cases up to -10dB.

Index Terms—LMS, RLMS, Kalman Filter, Steering Vector, Multi Antenna, Adaptive Beamforming, RKLMS, MIMO, SINR, Spatial Multiplexing, RLS.

I. INTRODUCTION

The rapid increase of wireless systems (smartphones, internet connected devices, surveillance devices, etc.) created unparalleled challenges for researchers to overcome resulting problems, i.e. channel congestion, by enhancing spectral utilization [1], [2]. To resolve the underlying issues and reduce spectral congestion, smart antenna systems using spatial multiplexing and adaptive signal processing techniques have been employed. Such systems minimize the impact of interference by creating a steerable beam pattern, i.e. beamforming, for directional signal transmission and reception [3], [4]. Moreover, the performance of such systems in rapid and precise tracking is highly correlated with the performance and complexity of the operating beamforming algorithms [3], [4]. Numerous algorithms exist for realizing an adaptive beamforming systems

with the most popular being the Least Mean Square (LMS) and Recursive Least Square (RLS). While the RLS algorithm can achieve faster convergence it does not offer acceptable tracking performance [5].

Several variants have been proposed for improving the convergence speed of LMS and tracking ability of RLS in time varying environments [4]. These techniques include variable step size LMS (VSSLMS) [6], the modified robust variable step size LMS (MRVSS) algorithm [7], the adaptive forgetting factor RLS algorithm (AFF-RLS) [8], the variable forgetting factor RLS (VFFRLS) and the extended recursive least square (EX-KRLS) algorithm [9].

In VSSLMS large step sizes are introduced at the beginning of the adaptation process and smaller ones as the algorithm approaches its steady state, allowing faster convergence and a lower residual error floor at the cost of a high increase in complexity [9]. To further increase VSSLMS noise immunity and tracking capabilities, the MRVSS algorithm has been proposed in [7]. Moreover, the robustness of the MRVSS and the improvement in the tracking ability of the RLS when implementing the VFFRLS, AFF-RLS and EX-KRLS algorithms are achieved at a considerably large increase in computation complexity [10], [11].

Recently, a novel RLMS approach for improving the convergence rate with superior tracking capabilities has been proposed [3], [4], [10], [11]. RLMS employs a RLS stage followed by a LMS stage separated by an estimate of the array image vector, i.e. steering vector with a delayed error feedback. This technique shows superior performance over previously discussed LMS and RLS variants with a relatively acceptable increase in computational complexity. Thus, for N antenna elements, and in addition to the LMS stage, the complexity is increased by $20N$ multiplications, $6N$ additions and $2N$ divisions for the steering vector estimate block.

In this context, the main motivation of this study is to further optimize the proposed RLMS in terms of complexity and robustness against low SINR, up to -10dB with an architecture suitable for a hardware based implementation. Such optimization is achieved by considering a parallel RLMS and parallel RLS with Kalman LMS (RKLMS) structures, eliminating the need for continuously computing the array image vector.

II. BACKGROUND REVIEW

A brief background review on some of the well known and widely used adaptive algorithms for narrow-band complex signals is presented in this section. Let the input vector at the discrete time instant k , $\mathbf{x}(k) = [x_1(k), x_2(k), \dots, x_N(k)]^T$, for a uniform linear antenna array with N elements, be defined by

$$\mathbf{x}(k) = \mathbf{a}_d s_d(k) + \mathbf{a}_i s_i(k) + \mathbf{n}(k) \quad (1)$$

with $[\cdot]^T$ being the matrix transpose, $s_d(k)$ and $s_i(k)$ are the desired and interfering signals, $\mathbf{a}_d$ and $\mathbf{a}_i$ are the $[N \times 1]$ complex array steering vectors for the desired signal and interference, and $\mathbf{n}(k)$ stands for the complex Additive White Gaussian Noise (AWGN) noise vector.

A general form of the steering vectors $\mathbf{a}_d$ and $\mathbf{a}_i$ is given by

$$\mathbf{a} = [1, e^{-j2\pi \frac{D \sin(\theta)}{\lambda}}, \dots, e^{-(N-1)j2\pi \frac{D \sin(\theta)}{\lambda}}]^T \quad (2)$$

where the first antenna element acting as a reference, θ is the angle of arrival, D is the distance between consecutive antenna elements, λ is the signal wavelength. Thus, the output $y(k)$ of the beamformer subject to a linear combiner is given by

$$y(k) = \mathbf{w}^H(k) \mathbf{x}(k) \quad (3)$$

where $[\cdot]^H$ represents the matrix Hermitian transpose and $\mathbf{w}(k)$ is the array weight vector.

A. Recursive Least Squares

The Recursive Least Square (RLS) algorithm updates the arrays weight vector based on the minimization of a cost function. Which is defined by the sum of squared errors for a known sampling window [10] and is given by

$$\zeta(k) \triangleq \sum_{i=1}^k \alpha^{k-i} |e_{RLS}(k-i)|^2 \quad (4)$$

where $e_{RLS}(k) = d(k) - y(k)$ is the error signal for the input and desired signals $\mathbf{x}(k)$ and $\mathbf{d}(k)$ respectively, $|\cdot|$ denotes the modulus and $\alpha \in [0, 1]$ is the exponential weighted forgetting factor. Hence, the weight vector update formula is as follow

$$e_{RLS}(k) = d(k) - \mathbf{w}^H(k-1) \mathbf{x}(k) \quad (5)$$

$$\mathbf{L}(k) = \frac{\alpha^{-1} \mathbf{Q}^{-1}(k-1)}{1 + \alpha^{-1} \mathbf{x}^H(k) \mathbf{Q}^{-1}(k-1) \mathbf{x}(k)} \quad (6)$$

$$\mathbf{w}(k) = \mathbf{w}(k-1) + \mathbf{L}(k) \mathbf{x}(k) e^*(k) \quad (7)$$

where $\mathbf{L}(k)$ is the gain matrix and the inverse signal auto-correlation matrix $\mathbf{Q}^{-1}(k)$ and the weight vector $\mathbf{w}(k-1)$ are given as follows

$$\begin{aligned} \mathbf{Q}^{-1}(k) &= \alpha^{-1} \mathbf{Q}^{-1}(k-1) \\ &- \frac{\alpha^{-2} \mathbf{Q}^{-1}(k-1) \mathbf{x}(k) \mathbf{x}^H(k) \mathbf{Q}^{-1}(k-1)}{1 + \alpha^{-1} \mathbf{x}^H(k) \mathbf{Q}^{-1}(k-1) \mathbf{x}(k)} \end{aligned} \quad (8)$$

$$\mathbf{w}(k-1) = \mathbf{Q}^{-1}(k-1) \mathbf{z}(k-1) \quad (9)$$

$$\mathbf{z}(k) = \sum_{i=1}^k \alpha^{k-i} d^*(i) \mathbf{x}(i) \quad (10)$$

$$\mathbf{Q}(k) = \sum_{i=1}^k \alpha^{k-i} \mathbf{x}(i) \mathbf{x}^H(i) \quad (11)$$

with $\mathbf{z}(k)$ is the cross-correlation vector between the input and the desired signal and $\mathbf{Q}(k)$ is the input signal auto-correlation matrix [3]. While RLS offers fast convergence, it lacks acceptable tracking ability.

B. Least Mean Squares

The Least Mean Square (LMS) algorithm minimizes the mean square error (MSE) $e_{LMS}(k)$, between the input and desired signals $\mathbf{x}(k)$ and $\mathbf{d}(k)$, by using the steepest descent optimization method [9]. LMS is computationally efficient and is used to estimate the gradient of the error signal to update the weight vector of the antenna array. The weight vector $\mathbf{w}(k)$ is updated as follows

$$e_{LMS}(k) = d(k) - y(k) \quad (12)$$

$$\mathbf{w}(k+1) = \mathbf{w}(k) + \mu e_{LMS}^*(k) \mathbf{x}(k) \quad (13)$$

where μ controls the magnitude of the gradient descent steps i.e. step size. While LMS offers superior tracking capabilities then RLS, it suffers from a trade off between its convergence speed and the steady state error [12].

C. LMS Kalman Filter Representation

Kalman's filter presents a realization of an optimal Bayesian estimator in a two step recursive process, i.e. prediction and correction. It is described by a state-space model which infers the parameters of interest from uncertain observations and is the core of many critical applications i.e. crowd-sensing [13], [14]. Therefore, Kalman's filter mathematical model for the LMS algorithm is given according to [12] by

$$\begin{aligned} \mathbf{g}(k) &= \frac{\mathbf{P}(k-1)}{\mathbf{x}^H(k) \mathbf{P}(k-1) \mathbf{x}(k) + \sigma_n^2} \mathbf{x}(k) \\ \mathbf{w}(k) &= \mathbf{w}(k-1) + \mathbf{g}(k) (d(k) - \mathbf{x}^H(k) \mathbf{w}(k-1)) \\ \mathbf{P}(k) &= \mathbf{P}(k-1) - \mathbf{g}(k) \mathbf{x}^H(k) \mathbf{P}(k-1) \end{aligned} \quad (14)$$

where $\mathbf{g}(k)$ is the optimal learning gain vector, $\mathbf{P}(k-1) = E[\tilde{\mathbf{w}}(k-1) \tilde{\mathbf{w}}^H(k-1)]$ is the error co-variance matrix, $E[\cdot]$ is the expectation operator, $\tilde{\mathbf{w}}(k-1) \triangleq \mathbf{w}_o(k-1) - \mathbf{w}(k-1)$ is the weight error vector, $\mathbf{w}_o(k)$ is the optimal weight vector and $\sigma_n^2 = E[|\mathbf{n}(k)|^2]$ is the noise variance as given in [12].

D. Cascade Form RLMS Beamformer

The Recursive-Least mean square (RLMS) algorithm is a RLS stage followed by a LMS stage separated by an estimate of the array image vector with a delayed error feedback [4] as shown in figure 1. In RLMS, the output of the first stage RLS_1 , $y_{RLS1}(k)$, is multiplied by the estimate of the desired signal steering vector $\hat{\mathbf{a}}_d$, forming the input, $\mathbf{x}_2(k)$, to the

Fig. 1. Cascaded RLMS

second LMS_2 stage. Moreover, $\tilde{\mathbf{a}}_d$, is given by its stochastic approximation near convergence [15]

$$\begin{aligned} a_{d,m}(k) &\simeq \frac{E[w_{1,m}(k)x_{1,m}(k)]}{E[w_{1,m}]y_{RLS1}(k) + \varepsilon} \\ &\simeq \frac{w_{1,m}(k)x_{1,m}(k)}{w_{1,m}(k)y_{RLS1}(k) + \varepsilon} \end{aligned} \quad (15)$$

where $w_{1,m}(k)$, $x_{1,m}(k)$ and $a_{d,m}$ are the RLS_1 tap weights, input signal and the estimate of the m th antenna element of the complex steering vector $\tilde{\mathbf{a}}_d$ at the time instant k with $m \in \{1, 2, 3, \dots, N\}$. Where ε is chosen as a small constant to prevent the division by zero. Moreover, a delayed version of the error signal $e_2(k)$ of the LMS_2 stage is fed-back to combine with that of the RLS_1 to form the overall error signal $e_{RLMS}(k)$ used to update the main tap weights of the RLS_1 stage. The overall error signal and the optimal tap weights are given by [10]

$$e_{RLMS}(k) = e_1(k) - e_2(k-1) \quad (16)$$

$$\mathbf{w}_o(k) = \mathbf{Q}^{-1}(k)\mathbf{z}_R(k) \quad (17)$$

where $\mathbf{z}_R(k)$ is an estimation of the input, $\mathbf{x}_1(k)$ assumed independent and identically distributed (iid), and the LMS_2 zero mean desired signal, $d_1(k)$, cross correlation vector

$$\mathbf{z}_R(k) = E[d_1^*(k)\mathbf{x}_1(k)] \quad (18)$$

while the RLMS presents accelerated convergence and superior tracking abilities, its cascaded form introduces high latency when targeting a hardware implementation with a division operation such as in equation (15). Furthermore, the system complexity is increased by $20N$ multiplications, $6N$ additions and $2N$ divisions for the steering vector estimated in equation (15).

III. PARALLEL RLMS

As our main motivation is to propose an optimized parallel RLMS structure with reduced complexity and noise robustness. This section details the derivation of the RLMS basis for the RKLMS structure.

A. Parallel RLMS

As previously defined, the input to the m^{th} antenna element for the LMS stage, $x_{2,m}(k)$, is defined by

$$x_{2,m}(k) = \frac{w_{1,m}(k)x_{1,m}(k)}{w_{1,m}(k)y_{RLS1}(k) + \varepsilon} \quad (19)$$

After a detailed inspection and since ε is a negligible user introduced constant, equation (19) can be simplified to

$$x_{2,m}(k) \approx x_{1,m}(k) \quad (20)$$

thus the input to the LMS stage, $x_2(k)$, is none other then the reconstructed RLS_1 input $x_1(k)$. The parallel RLMS can now be defined as shown in figure 2.

Fig. 2. Parallel RLMS

The parallel RLMS mean square error (MSE) is re-evaluated following the same assumptions in [10]: The propagation environment is time invariant, The components of the signal vector $\mathbf{x}(k)$ should be iid, and all signals are zero mean, wide sense stationary and spatially uncorrelated. Therefore, the MSE ξ_{RLMS} is given by

$$\begin{aligned} \zeta_{RLMS}(k) &\triangleq \sum_{i=1}^k \alpha^{k-1} E[|e_1(k) - j e_2(k-1)|^2] \\ &= \sum_{i=1}^k \alpha^{k-1} \{E[e_1(k)e_1^*(k) + j e_1(k)e_2^*(k-1) \\ &\quad - j e_1^*(k)e_2(k-1) + e_2(k-1)e_2^*(k-1)]\} \end{aligned} \quad (21)$$

where $j = \sqrt{-1}$ is the complex number resulting in a phase shift i.e. delay [9], $e_1(k)$ and $e_2(k-1)$ are the RLS and LMS errors respectively, $|\cdot|$ signifies modulus and $*$ is the complex conjugate operator. Moreover, the first term of equation (21) can be expressed as

$$\begin{aligned} E[|e_1(k)|^2] &= E[e_1(k)e_1^*(k)] \\ &= E[|d(k)|^2] - \mathbf{z}_R^H(k)\mathbf{w}_1(k) - \mathbf{w}_1^H(k)\mathbf{z}_R(k) \\ &\quad + \mathbf{w}_1^H(k)\mathbf{Q}(k)\mathbf{w}_1(k) \end{aligned} \quad (22)$$

correspondingly the last term of equation (21) can be expanded to become

$$\begin{aligned} E[|e_2(k-1)|^2] &= E[e_2(k-1)e_2^*(k-1)] \\ &= E[|d(k-1)|^2] - \mathbf{z}_R^H(k-1)\mathbf{w}_2(k-1) \\ &\quad - \mathbf{w}_2^H(k-1)\mathbf{z}_R(k-1) + \mathbf{w}_2^H(k-1)\mathbf{Q}(k-1)\mathbf{w}_2(k-1) \end{aligned} \quad (23)$$

Furthermore, the second and third terms of equation (21) can be written as

$$\begin{aligned} E[j e_1(k)e_2^*(k-1)] &= j E[d(k)d^*(k-1) \\ &\quad - d(k)\mathbf{x}^H(k-1)\mathbf{w}_2(k-1) - d^*(k-1)\mathbf{w}_1^H(k)\mathbf{x}(k) \\ &\quad + \mathbf{w}_1^H(k)\mathbf{x}(k)\mathbf{x}^H(k-1)\mathbf{w}_2(k-1)] \end{aligned} \quad (24)$$

and

$$\begin{aligned} E[-je_1^*(k)e_2(k-1)] &= -jE[d^*(k)d(k-1) \\ &\quad - d(k-1)\mathbf{x}^H(k)\mathbf{w}_1(k) - d^*(k)\mathbf{w}_2^H(k-1)\mathbf{x}(k-1) \\ &\quad + \mathbf{x}^H(k)\mathbf{w}_1(k)\mathbf{w}_2^H(k-1)\mathbf{x}(k-1)] \end{aligned} \quad (25)$$

where $\mathbf{w}_2(k-1)$ is the LM_{S_2} stage weight vector at time $k-1$. Thus, by using equations (22), (23), (24) and (25), the MSE defined in (21) can be rewritten as

$$\begin{aligned} \zeta_{RLMS}(k) &= \sum_{i=1}^k \alpha^{k-i} \{ E[|d(k)|^2] - \mathbf{z}_R^H(k)\mathbf{w}_1(k) \\ &\quad - \mathbf{w}_1^H(k)\mathbf{z}_R(k) + \mathbf{w}_1^H(k)\mathbf{Q}(k)\mathbf{w}_1(k) + E[|d(k-1)|^2] \\ &\quad - \mathbf{z}_R^H(k-1)\mathbf{w}_2(k-1) - \mathbf{w}_2^H(k-1)\mathbf{z}_R(k-1) \\ &\quad + \mathbf{w}_2^H(k-1)\mathbf{Q}(k-1)\mathbf{w}_2(k-1) + jE[d(k)d^*(k-1)] \\ &\quad - jE[d(k)\mathbf{x}^H(k-1)]\mathbf{w}_2(k-1) \\ &\quad - j\mathbf{w}_1^H(k)E[d^*(k-1)\mathbf{x}(k)] \\ &\quad + jE[d(k-1)\mathbf{x}^H(k)]\mathbf{w}_1(k) \\ &\quad - jE[d^*(k)d(k-1)] + j\mathbf{w}_2^H(k-1)E[d^*(k)\mathbf{x}(k-1)] \\ &\quad - jE[\mathbf{x}^H(k)\mathbf{w}_1(k)\mathbf{w}_2^H(k-1)\mathbf{x}(k-1)] \} \end{aligned} \quad (26)$$

with $\mathbf{w}_1(k)$ being the tap weights of interest, the optimal weight vector, $\mathbf{w}_o(k)$, of $\mathbf{w}_1(k)$ can be obtained by differentiating equation (26) with respect to $\mathbf{w}_1^H(k)$ using Wirtinger calculus [16], and equating the result to zero

$$\begin{aligned} \frac{\partial \zeta_{RLMS}(k)}{\partial \mathbf{w}_1^H(k)} &= -\mathbf{z}_R^H(k) + \mathbf{Q}(k)\mathbf{w}_1(k) \\ &\quad - jE[d^*(k-1)\mathbf{x}(k)] + jE[\mathbf{x}(k)\mathbf{x}^H(k-1)]\mathbf{w}_2(k-1) \end{aligned} \quad (27)$$

hence the optimal weight vector $\mathbf{w}_o(k)$ is represented as follows

$$\begin{aligned} \mathbf{w}_o(k) &= \mathbf{Q}^{-1}(k)\mathbf{z}_R^H(k) + j\mathbf{Q}^{-1}(k)E[d^*(k-1)\mathbf{x}(k)] \\ &\quad - j\mathbf{Q}^{-1}(k)E[\mathbf{x}(k)\mathbf{x}^H(k-1)]\mathbf{w}_2(k-1) \end{aligned} \quad (28)$$

IV. SIMULATION RESULTS

We ran several Monte Carlo simulations with 200 realizations of 200 samples each with $N = 8$ antenna elements. In addition, the input message and interfering signals are modeled as a random binary data stream modulated by binary phase shift keying (BPSK). The resulting signal is mixed with complex AWGN, with a signal to noise ratio $SNR = 10dB$. Simulations are conducted for LMS, RLS, KLMS, parallel RLMS, cascaded RLMS at $SNR = 10dB$. And using the parallel RLMS and proposed RKLMS for additional SNR test case of $-10dB$. The MSE is used to assess the convergence and performance of each case. In addition, simulation parameters for the LMS, RLMS variants and the Kalman LMS and RKLMS respectively, are given as, $\mu_{LMS} = 0.05$, $\mu_{RLMS} = 0.2$, $\alpha = 0.98$, $\mathbf{P}(0) = 0.5I$, $\mathbf{Q}^{-1}(0) = 0.025^{-1}I$, $\varepsilon = 256 \times 10^{-12}$ and $\sigma_n^2 = 1$, where I is a $[N \times N]$ identity matrix. Simulation results are in figures 3, 4, 5 and 6 respectively.

The presented results in figure 3 show the identical performance of the cascade and parallel based RLMS stages and

Fig. 3. RLMS and RKLMS Simulation Results for SNR 10dB

Fig. 4. LMS, KLMS and RLS, Simulation Results For SNR 10dB

better performance of the proposed RKLMS for $SNR = 10dB$. Moreover, the superior performance of the RKLMS to the traditional RLMS can be seen at $SNR = -10dB$ from figures 5 and 6 respectively, where the classical RLMS diverged while the RKLMS converged. Furthermore, the following increase in performance is given at the cost of a small increase in complexity by replacing the classical LMS stage with the KLMS whose performance over the latter was demonstrated in figure 4. Thus, we can state that the parallel RLMS is indeed the cascade RLMS [4], [10] where $20N$ multiplications, $6N$ additions and $2N$ divisions are reduced from the computational complexity. Thus, the resulting parallel structure has reduced the complexity and the latency. Therefore it becomes more suitable for a hardware implementation [17], [18].

V. CONCLUSION

In this paper, an efficient parallel RLMS adaptive beamformer, with identical performance over the traditional LLMS at $20N$ multiplications, $6N$ additions and $2N$ divisions re-

Fig. 5. RLMS Simulation Results For SNR -10dB Log-Log Plot

Fig. 6. RKLMS Simulation Results for SNR -10dB

duced complexity is presented. Moreover, a RKLMS is proposed for robustness against low SINR up to $SNR = -10dB$ cases by modeling the classical LMS stage with a Kalman LMS filter. Experimental results have shown satisfactory convergence and identical performance of the parallel RLMS and cascade RLMS validating the proposed approach. The results also validated the robustness of the RKLMS in low SINR scenarios with superior performance over the previously stated algorithm at a slight increase in complexity. While, presented simulations show promising results, they only consider the preset simulation parameters. However, the RLMS and RKLMS performance may be further optimized for additional robustness by wisely selecting the preset value of the initial parameters, i.e. step size and the error co-variance matrix. Thus, future work includes performing stability analysis to deduce the optimal initial parameters and implementing the parallel RKLMS structure on re-configurable hardware such as FPGA.
