Flavonoid

ABSTRACT

The present study aimed to determine the phytoconstituent compositions of the leaves of four *Ziziphus jujuba* ecotypes (Choutrana, Mahdia, Mahres and Sfax). The chromatographic peaks of 18 compounds, including nine major fatty acids, five sterols, two triterpene alcohols and two methylsterols, were quantified by the capillary gaseous chromatography method. The major fatty acids identified were linolenic (42.04%) and palmitic (23.04%). Unsaturated fatty acids ranged between 53% and 60%. The predominant sterols (mg/100 g) were 13-sitosterol (4036) and stigmasterol (24.18). Cycloartenol (68.55 mg/100 g) and citrostadienol (12.27 mg/100 g) were the major methylsterols. Methylene cycloartanol ranged between 1.2 mg/100 g (Sfax) and 1.5 mg/100 g (Mahdia). Total phenolic content measured by Folin-ciocalteux ranged from 3.97 mg GAE/g to 6.04 mg GAE/g. The predominant flavonoids identified by HPLC were apigenin (6.1 mg/g) and rutin (1.91 mg/g).

The fatty acids and flavonoids in the *Z. jujuba* leaves were responsible for their therapeutic and pharmaceutical effects. This could explain why Tunisian people traditionally use it as medicine to treat several pathologies.

1. Introduction

The *Ziziphus* genus is known for its widespread use in modern ethnomedicine, especially in arid and semi-arid areas (Borgi et al., 2008). *Ziziphus jujuba* was introduced in Tunisia a long time ago and is now well acclimated (Laamouri et al., 2008). Its various effects include antimicrobial, antioxidant, immuno-stimulant, anti-diabetic, hyperglycemic and anticancer (Preeti and Shalini, 2014; Sirajunnisa et al., 2014). The leaves have been used for herbal tea as a folk medicine for hemorrhaging and diarrhea (Mahajan and Chobda, 2009). They have also been used to improve sleep, nourish the heart and soothe the nerves (Zhang et al., 2014). Preeti and Shalini (2014) reported that extracts of *Ziziphus* leaves were used to treat children suffering from typhoid fever, furuncle and ecthyma; they were also used as an antipyretic and to reduce obesity. Other authors (Sirajunnisa et al., 2014) have confirmed that extracts of *Z. jujuba* leaves are an ecofriendly green inhibitor of aluminum corrosion in an NaOH solution. Oils extracted from different *Z. jujuba* organs (pulp, leaves and seeds) seem to be rich in fatty acids, sterols and triterpenes (Croueour et al., 2002; Lee et al., 2003). Most studies mainly focused on the pulp and seed oil composition. These oils, used for medicinal and pharmaceutical applications (hypotensive, antihypoxic and hypothermic), make up 12.35% and 37.5% of the dry weight of the pulp and seeds, respectively (Elaloui et al., 2011, 2014a,b). Others works have shown that the compounds extracted from leaves are limited and fragmented (Zhang et al., 2014). The richness of the leaf oil in omega-3, a compound responsible for many health benefits, explained their use to treat some allergic and inflammatory reactions (Bell et al., 2009).

Phytosterols, the main components that regulate fluidity and permeability of the membrane (Darnet and Rahier, 2004), have been used as intermediates to synthesize hormones (Hamama et al., 2003). Scientists have subdivided sterols into three groups: free sterols, steryl esters and steryl glucosides (Benveniste, 2004). In *Z. jujuba* oils, sterols ranged from 14 mg/100 g to 182 mg/100 g in the pulp and seeds (Elaloui et al., 2011, 2014a,b).

Triterpens have anti-inflammatory (Manez et al., 1997), antimicrobial (Suksamrarn et al., 2006) and antioxidant effects.
(Bowen-forbes et al., 2009; Liu et al., 2010). Triterpenic acids were isolated from Ziziphus leaves by Guo et al. (2011).

Polyphenols have been shown to have antimicrobial, anti-inflammatory, antitumor and anti-sweet effects (Selloum et al., 2003; Guo et al., 2011; Morado-Castillo et al., 2014). Flavonoids were identified in Z. jujuba leaf extracts (Guo et al., 2011; Pei et al., 2011). In Tunisia, the chemical composition of Z. jujuba leaves used as an herbal tea have hardly been studied. Hence, there was a strong need to thoroughly analyze the bioactive components of Z. jujuba leaves.

The present study was undertaken to investigate the fatty acids, sterols, methylsterols, triterpene alcohols and the polyphenol composition of the leaves of four Z. jujuba ecotypes (Sfax, Choutrana, Mahres and Mahdia) harvested in Tunisia.

2. Materials and methods

2.1. Plant material

Z. jujuba leaves (Fig. 1) were collected in August 2010 (the maximum foliation period) from 5-year-old plants cultivated in the experimental station of “Rouhia” in northwestern Tunisia (35°40′–15.39′′N; longitude 9°0.3′–15.29′′E; altitude 636 m). Plant botanical identification was carried out by a Professor Mohamed Boussaid and a voucher sample was deposited at the Herbario of the National Institute for Research in Rural Engineering, Water and Forests (INRGREF) in Tunisia. Dried leaves were first ground using a mill equipped with a grid with holes 1.00 mm in diameter and then stored in plastic bags until chemical analysis could be done in the ENSCIACET Laboratory, France.

2.2. Methods

2.2.1. Reagents and standards

All solvents used in this experiment were purchased from Sigma–Aldrich (Steinheim, Germany) and used as received, namely: tert-butyl-methyl ether (TBME), cyclohexane; KOH; N-methyl-N-trimethylsilyl-heptafluorobutyramide (MSHFBA); dihydrocholesterol; chloroform; homologous fatty acids and sterols, rutin and apigenin standards.

2.2.2. Lipid extractions

The dried and powdered leaves were Soxhlet-extracted with cyclohexane for 6 h. The extract, concentrated under reduced pressure using a rotary evaporator at 60 °C, was kept in darkness at 4 °C until analysis.

2.2.2.1. Fatty acids extraction. Fatty acids (FAs) were extracted in duplicate according the procedure used by Macherey Nagel of dissolving 20 mg of oils in 1 mL of TBME (Trimethylsulfonium hydroxide) solvent. Next, 50 μL of reagents were added to 100 μL of this solution. This methylation with TMSH was recommended for free acids, chlorophenoxyacetic acids, their salts and derivatives as well as for phenols and chlorophenols (Butte, 1983) in order to simplify the sample preparation. Lipids or triglycerides could be converted to the corresponding fatty acid methyl esters (FAMEs) by a simple transesterification. This reaction was very convenient, because only the reagent (0.2 M of methanol) was added to the sample solution. No excess reagent had to be removed since pyrolysis to volatilize methanol and dimethylsulfide will occur in the gas chromatograph injector at 250 °C. Due to the high reactivity, complete derivatization was often obtained at ambient temperature. However, heating (10 min at 100 °C) in a closed sample vial may be necessary.

2.2.2.2. Sterol extraction. Unsaponifiable compounds and sterols were extracted according to the method used by Elaloui et al. (2014a,b). 100 μg of dihydrocholesterol (internal standard dissolved in chloroform) was added to 140 mg of oil and mixed with 3 mL of a KOH solution (1 M in ethanol). After heating at 75 °C for 30 min, 1 mL of distilled water and 6 mL of isohexane were added to the mixture. The unsaponifiable fraction, separated by the isohexane, was analyzed by GC (Sriti et al., 2011). 160 μL of the organic phase containing the sample was added to 40 μL of silylation reagent (1 mL N-methyl-N-trimethylsilyl-heptafluorobutyramide (MSHFBBA) and 50 μL of 1-methylimidazole). After mixing, the total extract was heated for 5 min at 103 °C before GC analysis. The extractions were carried out in duplicate.

2.2.2.3. Polyphenol compounds

The contents of total phenolic compounds of extracts from four ecotypes of Z. jujuba leaves were assayed following the Singleton’s method, slightly modified by Dewanto et al. (2002). Levels were expressed as mg of gallic acid equivalents per gram of dry weight (mg GAE/g DW), using gallic acid as a standard. So, we prepared dilutions (0–100 mg/L) from gallic acid (2 g/L) solution. Then we added an aliquot (0.125 mL) of a suitable diluted methanolic leaf extract to 0.5 mL of deionized water and 0.125 mL of the Folin–Ciocalteu reagent. The mixture was shaken and allowed to stand for 6 min before adding 1.25 mL of 7% Na2CO3 solution. The solution was then adjusted with deionized water to a final volume of 3 mL and mixed thoroughly. The absorption was carried out in triplicate using a SHIMADZU UV-1800 spectrophotometer at 760 nm after incubation for 90 min at 23 °C.

Dilutions were made in duplicate and phenolic levels were measured after a calibration curve.

2.2.2.4. HPLC analysis

The powdered leaves (2.5 mg) were submitted to maceration for 6 h with acetone–water (4:1, v/v) at room temperature. The...
acetonitrile extract was then filtered and a second maceration was done. The supernatants were combined and the acetonite was evaporated at 40°C in a vacuum. The solution was filtrated with 0.45 mm pore-sized membrane filters (Vivascience AG, Hanover, Germany) before HPLC injection. Investigated components were identified by comparing their retention times with those obtained from injecting standards under the same conditions. The extractions were carried out in duplicate.

2.2.5. Analysis conditions
FA was analyzed, in triplicate, using a capillary gaseous chromatography Varian (CPG). The mixture was injected directly. The temperature of the injector had to be at least 250°C. The column used was Select CB for FAME fused silica WCOT (50 m × 0.25 mm, 0.25 μm film thickness). The temperature gradient was 185°C for 40 min, then 15°C/min to 250°C, and 250°C for 10 min. The analysis time was 55 min. The FID detector was set up at 250°C. The Helium was the carrier gas at 1.2 mL/min.

Sterol was analyzed by GC using a flame ionization detector (FID) PerkinElmer (Waltham, MA, USA) chromatograph. A CP-SIL 8CB capillary column (30 m; 0.25 mm; 0.25 μm) was used. The column oven temperature was set at a rate of 20°C/min from 160 to 260°C, 2°C min⁻¹ to 300°C and 45°C min⁻¹ up to 350°C. The quantity of injected sample was 1 μL. Helium was the carrier gas with a flow of 1 mL/min (using on column injection). The detector was set at 360°C with an injection volume of 1 μL. The compounds were identified by comparing them to the commercial standards. Sterols were quantified by internal calibration after adding cholestanol. The sterols analyzed and cholestanol were observed to respond in the same way.

The compounds were identified by comparing them to the commercial standards. Sterols were quantified by internal calibration after adding cholestanol. The sterols analyzed and cholestanol were observed to respond in the same way.

Rutin and apigenin analyses were carried out via HPLC Dionex (P680-ASI 8100-Agilent). They were separated using a C18 column (5 μm, 4.6 mm × 150 mm).

The eluent was a mixture of 3% acetic acid (in water) (solvent A) and 100% methanol (solvent B). The first, HPLC was stabilized to 20% (B) in 10 min, then increased from 60% at 28 min to 80% at 3 min. Elution was done at a flow rate of 0.8 ml/min. Compounds were identified by comparing them to the commercial standards. The column was washed between two successive injections with methanol. Results were expressed in mg/g dry weight.

2.2.6. Statistical analysis
Results were statistically evaluated using STATISTICA (Statsoft, 1998). Data from three samples was reported as means ± standard deviation. Differences were tested for significance with the ANOVA procedure using the Duncan test with a significance level of p < 0.05.

3. Results
As shown in Fig. 2, the oil yields obtained from Z. jujuba leaves ranged from 8.61% to 10.31% based on dry weight. Sfax was the richest ecotype and Choutrana had the poorest oil content.

3.1. Free fatty acids
The typical GC profile (Fig. 5) showed a large variation in fatty acid content between the four ecotypes (Sfax, Choutrana, Mahres and Mahdia).

In order of decreasing values, the major FAs in these oils (Table 1) were: linolenic acid = omega-3 (42.04%), palmitic acid (23.04%), oleic acid (13.08%), linoleic acid (12.19%), stearic acid (9.8%), behenic acid (3.47%) and myristic acid (2.5%). This large qualitative and quantitative oil composition of Z. jujuba leaves enhances its use in pharmacology and cosmetics.

The large proportion of linolenic acid (omega-3) illustrates the high levels of unsaturated FAs (the sum of monounsaturated and poly-unsaturated FAs), varying from 53% to 60%. The richness of unsaturated FAs, which have a multitude of uses in pharmacological activities, could reduce the incidence of human illnesses such as coronary heart disease, other heart diseases, diabetes, and certain types of cancer. This richness also means that leaf extracts have a high nutritional value. Some authors have confirmed this evidence (Berra, 1998; Lunn and Theobald, 2006).

3.2. Sterols
The sterol content of Z. jujuba leaves is presented in Table 2. Sterol levels reached up to around 64 mg/100 g. β-sitosterol and stigmasterol were among the major components in all ecotypes (Fig. 6).

β-sitosterol was high for all ecotypes, with the maximum in the Mahdia ecotype (40.36 mg/100 g oil). This sterol was down to 37.32 mg/100 g oil in Mahres ecotype. It was detected at levels of 32.25 mg/100 g oil and 33.77 mg/100 g oil in Choutrana and Sfax, respectively. The stigmasterol varied from 18.06 (Sfax) to 24.16 mg/100 g oil (Mahdia).

Others sterols such as delta-5-avenasterol were present in the Z. jujuba leaves at levels of 6.91, 6.19, 5.2 and 3.88 mg/100 g oil in Mahdia, Sfax, Mahres and Choutrana, respectively. The campesterol was detected only in Sfax, Mahdia and Choutrana with 1.1, 0.8 and 0.6 mg/100 g oil, respectively.

Stigmasterol was present in Z. jujuba leaves at a level of 2.29 mg/100 g oil but only in the Sfax ecotype.

This information on the phytosterol composition of Z. jujuba leaves confirms the use of this plant to heal many ailments and incites further investigation for natural cosmetic products (Chebouat et al., 2013). In fact, plant sterols are very important to human health as well and can reduce dietary and biliary cholesterol absorption in the intestine (Harrabi et al., 2007).

Table 2 also shows the approximate composition of triterpene alcohols and methyl sterol fractions of the four ecotype leaf extracts. Of these compounds, squalene, cycloartenol and citrostadienol were the main components of these fractions. Methylene cycloartenol was only detected in Mahdia and Sfax ecotypes at levels of 1.47 and 1.18 mg/100 g oil, respectively. This richness of triterpene alcohols and methyl sterols, especially citrostanidiol, is important because they may be used as antioxidants (Malecka, 2002).

2.2.6. Statistical analysis
Results were statistically evaluated using STATISTICA (Statsoft, 1998). Data from three samples was reported as means ± standard deviation. Differences were tested for significance with the ANOVA procedure using the Duncan test with a significance level of p < 0.05.

3. Results
As shown in Fig. 2, the oil yields obtained from Z. jujuba leaves ranged from 8.61% to 10.31% based on dry weight. Sfax was the richest ecotype and Choutrana had the poorest oil content.

3.1. Free fatty acids
The typical GC profile (Fig. 5) showed a large variation in fatty acid content between the four ecotypes (Sfax, Choutrana, Mahres and Mahdia).

In order of decreasing values, the major FAs in these oils (Table 1) were: linolenic acid = omega-3 (42.04%), palmitic acid (23.04%), oleic acid (13.08%), linoleic acid (12.19%), stearic acid (9.8%), behenic acid (3.47%) and myristic acid (2.5%). This large qualitative and quantitative oil composition of Z. jujuba leaves enhances its use in pharmacology and cosmetics.

The large proportion of linolenic acid (omega-3) illustrates the high levels of unsaturated FAs (the sum of monounsaturated and poly-unsaturated FAs), varying from 53% to 60%. The richness of unsaturated FAs, which have a multitude of uses in pharmacological activities, could reduce the incidence of human illnesses such as coronary heart disease, other heart diseases, diabetes, and certain types of cancer. This richness also means that leaf extracts have a high nutritional value. Some authors have confirmed this evidence (Berra, 1998; Lunn and Theobald, 2006).

3.2. Sterols
The sterol content of Z. jujuba leaves is presented in Table 2. Sterol levels reached up to around 64 mg/100 g. β-sitosterol and stigmasterol were among the major components in all ecotypes (Fig. 6).

β-sitosterol was high for all ecotypes, with the maximum in the Mahdia ecotype (40.36 mg/100 g oil). This sterol was down to 37.32 mg/100 g oil in Mahres ecotype. It was detected at levels of 32.25 mg/100 g oil and 33.77 mg/100 g oil in Choutrana and Sfax, respectively. The stigmasterol varied from 18.06 (Sfax) to 24.16 mg/100 g oil (Mahdia).

Others sterols such as delta-5-avenasterol were present in the Z. jujuba leaves at levels of 6.91, 6.19, 5.2 and 3.88 mg/100 g oil in Mahdia, Sfax, Mahres and Choutrana, respectively. The campesterol was detected only in Sfax, Mahdia and Choutrana with 1.1, 0.8 and 0.6 mg/100 g oil, respectively.

Stigmasterol was present in Z. jujuba leaves at a level of 2.29 mg/100 g oil but only in the Sfax ecotype.

This information on the phytosterol composition of Z. jujuba leaves confirms the use of this plant to heal many ailments and incites further investigation for natural cosmetic products (Chebouat et al., 2013). In fact, plant sterols are very important to human health as well and can reduce dietary and biliary cholesterol absorption in the intestine (Harrabi et al., 2007).

Table 2 also shows the approximate composition of triterpene alcohols and methyl sterol fractions of the four ecotype leaf extracts. Of these compounds, squalene, cycloartenol and citrostadienol were the main components of these fractions. Methylene cycloartenol was only detected in Mahdia and Sfax ecotypes at levels of 1.47 and 1.18 mg/100 g oil, respectively. This richness of triterpene alcohols and methyl sterols, especially citrostanidiol, is important because they may be used as antioxidants (Malecka, 2002).

The data are mean values of three measurements ± SD (standard deviation). For each column, values with the same letter indicate no significant difference at 5%.

### 3.3. Total polyphenol contents

As shown in Fig. 3, the relative amounts of polyphenols in *Z. jujuba* leaves varied between 3.97 mg GAE/g (Sfax ecotype) and 6.04 mg GAE/g (Mahres ecotype).

The typical GC profile showed a large variation between the four ecotypes (Sfax, Choutrana, Mahres and Mahdia). The major flavonoid observed was Apigenin with a rate of about 6.1 mg/g of dried material in the Sfax ecotype. Mahres leaves exhibited an intermediate rate of about 0.9 mg/g. The lowest value (0.2 mg/g) was observed in the Choutrana ecotype.

Rutin was the second highest polyphenol from the leaf extracts at levels of 1.9 mg/g and 0.9 mg/g of the total polyphenols in the Sfax and Mahdia ecotypes, respectively (Fig. 4). Rutin rates decreased slightly to 0.45 mg/g and 2 mg/g in leaves from the Mahres and Choutrana ecotypes, respectively.

![Fig. 3.](image-url) Total phenolic contents (mg GAE/g) of four provenances of *Ziziphus jujuba* leaf extracts. The data are mean values of three measurements. The confidence intervals were calculated at the threshold of 5%.
Knowing the rutin and apigenin content in *Z. jujuba* leaves can be useful in order to implement them in pharmaceutical drugs and food supplements. In fact, polyphenols have attracted high interest from scientists due to their wide range of effects such as antimicrobial, anti-inflammatory, antitumor and anti-sweet (Selloum et al., 2003; Guo et al., 2011).

4. Discussion

The results of the free fatty acids of *Z. jujuba*, especially linolenic acid (42.04%) and palmitic acid (23.04%), were quite different from those reported for *Z. lotus*, where the main compounds were oleic acid (88.12%) and elaidic acid (7.88%) (Chazghazi et al., 2014). Wei et al. (2014) noted a higher value of linoleic acid (62.04%) in *Averrhoa carambola* leaves.

Unsaturated FA levels found in *Z. jujuba* leaves grown in Tunisia were compared to those obtained by Abedddaim et al. (2014) for
Ziziphus lotus fruits (71%). Wei et al. (2014) once again noted higher values for unsaturated fatty acid levels with 77% in A. carambola.

Stigmasterol and β-sitosterol were the predominant sterols in leaf extracts. This was confirmed by Elaloui et al. (2011, 2014a,b) in Z. jujuba pulp and seed extracts. She obtained 27.32 mg/100g and 16.12 mg/100g for stigmasterol and 214.32 mg/100g and 10.65 mg/100g for β-sitosterol in seeds and pulp, respectively. Other sterols such as stigmast-5-en-3β, 7α-diol and stigmast-5, 22-ene-3β, 7α-diol have been isolated from the Z. jujuba pulp (Wu et al., 2014a,b).

Suttisri et al. (1995) mentioned the existence of triterpenoids in leaf extracts of the Ziziphus species but no study found cycloartenol and citrostadienol in such products.

However, focusing on Z. jujuba pulp, Lee et al. (2003) showed that they were rich in triterpenic acids such as colubrinic, alphatic oleanolic, betulinic, zizyberenic and betulin. Wu et al. (2014a,b) detected three other triterpenoids (ilexsaponin B1, ilexsaponin B2 and musaendoside) in the ilex urceolatus species.

The polyphenol contents of Tunisian Z. jujuba leaves were less abundant (6.04 mg/L) than those found by Li et al. (2007) (8.53 mg/L). This difference could be explained by the richness of Tunisian Z. jujuba in the proanthocyanin which causes decreased levels of phenolic contents (Saleh et al., 2011). Others studies have shown that Tunisian Z. jujuba pulp (extracted under the same conditions) contained between 10.43 mg/L and 15.85 mg/L of polyphenols (Elaloui et al., 2014a,b).

The rutin ratio found in this study was greater (0.9–1.9 mg/g) than that obtained (0.3 mg/g) from Heteropterys tomentosa leaves (Paula-Freire et al., 2013). This work confirmed Z. jujuba leaves' richness in rutin compared to that found in the pulp (Elaloui et al., 2014a,b). In fact, according to that author, the pulp only contained 0.01 mg/g of rutin.

The variation in polyphenol levels between species could be explained by many genetic and environmental conditions (light, ripeness, maturity…). This idea has been confirmed by other authors (Bravo, 1988; Duthie et al., 2000; Chu et al., 2000).

The extraction efficiency (solvents, methods and times) and this dyeing techniques could influence polyphenol levels in the leaf extracts (Guo et al., 2011; Lee et al., 2003).

5. Conclusion

The biochemical characterization showed that Z. jujuba leaf extracts were distinct due to their richness in linolenic, palmitic, oleic, and linoleic acids, and in β-Sitosterol, stigmasterol and flavonoid compounds (especially rutin and apigenin) that justified their use in cosmetics and in pharmacology. The unconventional and underutilized Z. jujuba leaves had an interesting biochemical composition that could have a variety of uses and benefits. This work could help preserve this species by integrating it into sustai-

nable agro-sylv-o-pastoral development, especially in Tunisian arid regions.
