Abstract

The sequence and genomic organization of the *CACNA1A* gene that encodes the Cav2.1 subunit of both P and Q type Ca^{2+} channels are well conserved in mammals. In human, rat and mouse *CACNA1A*, the use of an alternative acceptor site at the exon 46-47 boundary results in the expression of a long Cav2.1 splice variant. In transfected cells, the long isoform of human Cav2.1 produces a C-terminal fragment, but it is not known whether this fragment affects Cav2.1 expression or functional properties. Here, we cloned the long isoform of rat Cav2.1 (Cav2.1(e47)) and identified a novel variant with a shorter C-terminus (Cav2.1(e47s)) that differs from those previously described in the rat and mouse. When expressed in *Xenopus laevis* oocytes, Cav2.1(e47) and Cav2.1(e47s) displayed similar functional properties as the short isoform (Cav2.1). We show that Cav2.1 isoforms produced short (CT1) and long (CT1(e47)) C-terminal fragments that interacted *in vivo* with the auxiliary Cav β 4a subunit. Overexpression of the C-terminal fragments did not affect Cav2.1 expression and functional properties. Furthermore, the functional properties of a Cav2.1 mutant without the C-terminal Cav β 4 binding domain (Cav2.1 Δ CT2) were similar to those of Cav2.1, and were not influenced by the co-expression of the missing fragments (CT2 or CT2(e47)). Our results exclude a functional role of the C-terminal fragments in Cav2.1 biophysical properties in an expression system widely used to study this channel.

1 INTRODUCTION

Voltage gated Ca^{2+} channels are heteromultimeric assemblies of the pore-forming $\text{Cav}\alpha 1$ subunit and of the auxiliary subunits $\text{Cav}\beta$ and $\text{Cav}\alpha 2\delta$. The human genome contains ten genes encoding $\text{Cav}\alpha 1$ subunits ($\text{Cav}1.1$ to 1.4 , $\text{Cav}2.1$ to 2.3 and $\text{Cav}3.1$ to 3.3), four genes encoding $\text{Cav}\beta$ subunits ($\text{Cav}\beta 1-4$), and four genes encoding $\text{Cav}\alpha 2\delta$ subunits ($\text{Cav}\alpha 2\delta 1-4$). The interactions between $\text{Cav}\alpha 1$ and its auxiliary subunits determine the channel expression level and functional properties (Buraei & Yang, 2010). The $\text{Cav}2.1$ subunit is the pore-forming subunit of the P- and Q-type Ca^{2+} channels (Pinto *et al.*, 1998; Jun *et al.*, 1999) that are widely expressed in the central nervous system, particularly in the cerebellum where they were first described (Mintz *et al.*, 1992; McDonough *et al.*, 1996). The pharmacological and functional properties that differentiate P- from Q-type channels result from alternative splicing of the $\text{Cav}2.1$ subunit and specific co-expression of one auxiliary $\text{Cav}\beta$ subunit (Hans *et al.*, 1999; Kanumilli *et al.*, 2006). C-terminal $\text{Cav}2.1$ variants are created by insertion/omission of the GGCAG sequence at the beginning of exon 47 (Fig. 1). However, this insertion is not the only event that diversifies the C-terminal extremity of $\text{Cav}2.1$. Specifically, the rabbit BI-1 variant lacks the GGCAG insertion, but harbors a sequence closely related to that found in human exon 47 (Andrés-Mateos *et al.*, 2006). Conversely, the rabbit BI-2 variant results from the removal of the exon 46 end and the first third of exon 47 (Mori *et al.*, 1991). Similar recombination events have also been described in the human *CACNA1A* gene, although they lead to isoforms that are completely different from BI-2 (Zhuchenko *et al.*, 1997; Veneziano *et al.*, 2009). A mouse isoform with a fully translated exon 47, similar to the human sequence, has been described (Richards *et al.*, 2007), but other isoforms also exist. For instance, MP11 (BAB85612) results from the use of an alternative acceptor site at the beginning of exon 47 (Fig. 1) that leads to the expression of a unique sequence up to the deletion of a single base allowing the recovery of the original reading frame of the fully translated exon 47. Therefore, MP11 C-terminus is

close to that of the human subunit (Tsunemi *et al.*, 2002). In the MPI isoform (BAB85611), deletion of 150 nucleotides in exon 47 produces a translational frameshift, leading to a specific C-terminal sequence (Tsunemi *et al.*, 2002). Given the high degree of sequence conservation in Cav2.1 and the similarities in the *CACNA1* gene organization in different species (Soong *et al.*, 2002; Kanumilli *et al.*, 2006), such variability in the Cav2.1 C-terminus is quite intriguing. Moreover, it is not clear whether and how these specific sequences affect the functional properties of Cav2.1 channels.

Interestingly, when the human Cav2.1 subunit is expressed in HEK cells, a 60-75kDa fragment (α 1ACT) that contains a tract of glutamine residues (polyQ) can be detected in cell nuclei with antibodies against the Cav α 1 C-terminus (Kubodera *et al.*, 2003; Kordasiewicz *et al.*, 2006). The α 1ACT protein is translated through an internal ribosome entry site (IRES) located within the mature mRNA encoding the Cav2.1 subunit (Du *et al.*, 2013), and may act as a transcription factor that modulates the expression of genes involved in neural development (Du *et al.*, 2013). Importantly, α 1ACT harboring a pathologic polyQ expansion, as observed in spinocerebellar ataxia type 6 (SCA6), cannot upregulate these genes (Du *et al.*, 2013; Ishida *et al.*, 2016; Bavassano *et al.*, 2017). SCA6 is an autosomal dominant cerebellar ataxia caused by expansion of this polyQ tract and characterized by the formation of insoluble aggregates in cerebellar Purkinje cells. Due to alternative splicing, the polyQ expansion is present in the Cav2.1 subunit with an extended C-terminus, but not in the short isoforms (Zhuchenko *et al.*, 1997). Studies on the functional impact of the pathological polyQ expansion in Cav2.1 gave rise to discrepancies, probably due to differences in the used Cav2.1 isoforms and/or cell lines (Matsuyama *et al.*, 1999; Restituito *et al.*, 2000; Toru *et al.*, 2000; Piedras-Renteria *et al.*, 2001). However, the functional properties of human Cav2.1 harboring a pathological polyQ expansion are not affected in Purkinje cells isolated from a knock-in mouse model of SCA6 (Saegusa *et al.*, 2007).

Unlike many other species, the rat and mouse *Cacnala* genes are devoid of CAG repeats (Andrés-Mateos *et al.*, 2006), thus precluding the additional level of complexity of $\alpha 1$ ACT functions brought by the polyQ expansion. Rat Cav2.1 with an extended C-terminus encoded by exon 47 (called herein Cav2.1(e47)) (Fig. 1) has not been functionally characterized yet and only the short variant Cav2.1 (called herein Cav2.1) is currently available for functional studies. Therefore, here we used *Xenopus laevis* oocytes, a heterologous expression system that has been used to study Cav2.1 calcium channels for nearly three decades, to determine whether a similar C-terminal fragment is produced also in oocytes that express rat Cav2.1, and whether co-expression of this fragment and Cav2.1 affects the channel properties. Indeed, Cav α 1 C-terminus interacts with the Cav β 4 subunits or other regions of the Cav α subunit (Sandoz *et al.*, 2001; Geib *et al.*, 2002). To this aim, we cloned a novel variant of the extended rat Cav2.1 C-terminus (Cav2.1(e47s)), in addition to Cav2.1(e47). We found that the electrophysiological properties of Cav2.1(e47) and Cav2.1(e47s) do not differ from those of Cav2.1, when expressed in *X. laevis* oocytes with Cav β 4a, β 1b or β 2a. Moreover, Cav2.1, Cav2.1(e47) and Cav2.1(e47s) produced C-terminal fragments equivalent to those produced by the human gene. These short and long C-terminal fragments (CT1 and CT1(e47), respectively) interacted with Cav β 4a in co-immunoprecipitation assays. Co-expression of C-terminal fragments with Cav2.1 or with a truncated Cav2.1 that lacks most of the C-terminus did not affect the channel expression or functional properties. Our study brings new important findings on rat Cav2.1 isoforms and clarifies the role of the C-terminal fragments expressed with the full-length channel in *X. laevis* oocytes.

2 MATERIAL AND METHODS

2.1 Molecular biology

The rat brain Cav2.1 (Genbank accession number AAA40806), Cav β 1b (CAA43665), Cav β 2a (AAK14821), Cav β 4a (A45982), and Cav α 2 δ 1 (AAG28164) cDNAs were cloned in the pMT2 and pcDNA3.1(+) (for Cav α 2 δ 1) expression vectors. The fragment encoding Cav2.1 exon 47 was obtained by RT-PCR using specific oligonucleotides and rat cerebellum total RNA (Agilent Technologies). Sequencing of several clones after cloning in the pBS-SK vector (Agilent technologies) revealed the existence of two fragments: TCA50 (full length exon 47) and TCA56 (with a 213nt deletion). They were cloned in frame with rat Cav2.1 in pMT2 using conventional molecular biology techniques to obtain Cav2.1(e47) and Cav2.1(e47s), respectively. Cav2.1, Cav2.1(e47) and Cav2.1(e47s) were also cloned in the pEGFP-N1 expression vector (Clontech) in frame with GFP to obtain Cav2.1-GFP, Cav2.1(e47)-GFP and Cav2.1(e47s)-GFP. The C-terminal fragments CT1, CT1(e47), CT2, and CT2(e47) were PCR amplified, cloned in frame with the RGS-6His tag in a modified pEGFP-N1 vector in which the GFP-encoding sequence was exchanged with the sequence encoding the RGS-6His tag to obtain CT1-6His, CT1(e47)-6His, CT2-6His, and CT2(e47)-6His. CT1 and CT1(e47) were also cloned in pEGFP-N1 in frame with GFP to generate CT1-GFP and CT1(e47)-GFP. For the production of Cav2.1 Δ CT1 and Cav2.1 Δ CT2, a stop codon was introduced by PCR after residue K1906 (numbered according to the AAA40806 sequence) or A2043, respectively. The amplified C-terminal fragments were cloned in pBS-SK, fully sequenced, and then, conventional molecular biology techniques were used to put them at the place of the full length Cav2.1 C terminus. For *X. laevis* oocyte injections, a cDNA mixture at a molar ratio of 1:1:1 (Cav α :Cav β :Cav α 2 δ) was prepared with the addition of water or the cDNA encoding one of the C-terminal fragments tagged with RGS-6His at a molar ratio of 1:1:1:1, unless otherwise indicated.

2.2 Ethical statement

This study was carried out in strict accordance with the recommendations and relevant guidelines of our institution. Surgery was performed under anesthesia, and efforts were made to minimize suffering. The care and use of *Xenopus* conformed to institutional policies and guidelines. The experimental protocols were approved by the "Direction Départementale des Services Vétérinaires" (authorization N° C34.16).

2.3 *X. laevis* oocyte preparation and injection

Preparation and injection of *X. laevis* oocytes were done as previously described (Cens *et al.*, 1996). After injection of about 15 ng of cDNA, oocytes were maintained at 19°C in NDS buffer (96 mM NaCl, 2 mM KCl, 1.8 mM CaCl₂, 1 mM MgCl₂, 5 mM Hepes, 2.5 mM Na-Pyruvate, 0.05 mM gentamycin, pH 7.2 with NaOH) renewed daily.

2.4 Electrophysiology

Expressed currents were recorded at room temperature using the two-electrode voltage clamp method at day 1-3 after injection, as previously described (Cens *et al.*, 2008). Electrodes were pulled from borosilicate glass and filled with 3M KCl. Currents were recorded with a Geneclamp 500 amplifier (Molecular Devices), and digitized with a Digidata 1200 converter (Molecular Devices) using the Clampex software (Molecular Devices). The external solution (10mM BaOH, 20mM TEAOH, 2mM CsOH, 50mM N-methyl-D-glucamine, 10mM HEPES, pH 7.2 with methane sulfonic acid) was continuously perfused in the recording chamber at the rate of 1 mL/min.

Currents were elicited by a two-pulse protocol from a holding potential of -100 mV. The first pulse lasted for 2.5 s and varied from -80 to +50 mV in 10 mV increments. The second pulse, separated from the first pulse by a 10 ms interval at -100 mV, lasted for 400 ms and was set at +10 mV. The isochronal inactivation curves were obtained by measuring the peak amplitude of the current evoked by the second pulse and by plotting the normalized current values (I/I_{max})

as a function of the voltage reached during the first pulse. They were fitted using the following equation:

$$I/I_{\max} = R_{\text{in}} + (1 - R_{\text{in}})/(1 + \exp((V - V_i)/k))$$

where I is the current amplitude measured during the second pulse following a first depolarization to V , $I_{\max}$ is the current amplitude measured during the second pulse following a first pulse at -80 mV, V_i is the half inactivation potential, k is a slope factor and R_{in} is the portion of non-inactivating current.

Currents were also elicited by single 400 ms-long depolarizations varying from -60 mV to $+40$ mV, from a holding potential of -100 mV. Current-voltage curves were obtained by measuring the peak amplitude and by plotting the normalized current values ($I/I_{\max}$) as a function of the voltage. They were fitted using the following equation:

$$I/I_{\max} = G (V - E_{\text{rev}})/(1 + \exp((V - V_a)/k))$$

where I is the current amplitude measured during the depolarization to V , $I_{\max}$ is the peak current amplitude measured at the maximum of the current-voltage curve, G is the normalized macroscopic conductance, E_{rev} is the apparent reversal potential, V_a is the potential for half activation, and k is a slope factor. The inactivation velocity (R_{400}) was estimated as the percentage of the peak current that disappeared after 400ms-long depolarizations to $+10$ mV.

Recovery from inactivation was determined using a protocol with two pulses at $+10$ mV for 5 s or 100 ms, respectively, from a holding potential of -100 mV, separated by an interval of time between 100 ms and 8 s. Traces were normalized to the maximum current measured during the first pulse. The percentage of current recovered during the second pulse was plotted as a function of the inter-pulse interval. Traces were fit with a double exponential equation.

2.5 Western blotting and immunoprecipitation assays

Oocytes that expressed Cav α 1-GFP alone or with 6His-tagged C-terminal fragments were harvested in 10 mM Tris HCl pH 7.5, 1 mM PMSF, 1 mM EDTA pH 8, and Complete Protease

Inhibitor (Roche). Lysates were homogenized with one volume of 2% Triton X100, 20 mM Tris pH 7.5, 300 mM NaCl, 1 mM EDTA, and incubated on ice for 1 hour. A volume of lysate corresponding to ~2 oocytes (i.e., an amount sufficient to generate ~4 μ A total current amplitude measured at +10 mV) was separated on Mini-PROTEAN® TGX™ Pre-Cast Gels (BioRad). Immunoblotting was performed with rabbit anti-GFP (1:5000, Sigma-Aldrich Cat#SAB4301138, RRID: AB_2750576), and mouse anti-RGS6His (1:1000, QIAGEN Cat#3460, RRID: AB_2687898), and horseradish peroxidase-conjugated goat anti-rabbit (1:5000, Sigma-Aldrich Cat#A0545, RRID: AB_257896) antibodies or horseradish peroxidase-conjugated goat anti-mouse (1:5000, Sigma-Aldrich Cat#A9917, RRID: AB_258476). HEK293 cells (RRID: CVCL_0045) were transfected with CT1-GFP or CT1(e47)-GFP alone, or together with Cav β 4 using Lipofectamine (ThermoFisher). At 24h post-transfection, cells were harvested in RIPA Lysis Buffer (Boster) with 1 mM PMSF, 1 mM EDTA pH 8, and Complete Protease Inhibitor. Cell lysates were incubated with a prewashed slurry of 20 μ l anti-GFP-Trap® A beads (Chromotek) at 4°C for 2h. Immunoprecipitates were recovered in 0.2 M glycine pH 2.5. Cells lysates and immunoprecipitates were analyzed separately using rabbit anti-GFP (1:5000), mouse anti-Cav β 4 (1:1000, abcam Cat#85788, RRID: AB_1860050), rabbit anti-GAPDH (1:5000, Sigma-Aldrich Cat#G9545, RRID: AB_796208), and horseradish peroxidase-conjugated goat anti-rabbit (1:5000) or goat anti-mouse (1:5000) antibodies. Detection was performed with the Western Lightning Plus (Perkin Elmer) reagents.

2.6 Data analysis

Results were expressed as the mean $\pm$ SEM. The statistical significance of differences between two groups was determined using the non-paired Student's *t* test.

3 RESULTS

3.1 Cloning and functional expression of two long variants of the rat Cav2.1 subunit

A cDNA fragment (AAC24516) encoding the entire exon 47 of the rat Cav2.1 calcium channel was previously isolated from pancreas (Ligon *et al.*, 1998), and a partial clone that lacks 123 nucleotides in exon 47 sequence (CAJ09863) was obtained from rat Purkinje neurons (Kanumilli *et al.*, 2006)(Fig. 1). However, to our knowledge, no cDNA encoding the rat Cav2.1 with the long C-terminus is available for functional studies. Therefore, we designed oligonucleotides to amplify rat exon 47 from cerebellum RNA and obtained two different variants. The first one (TCA50, Fig. 1) encoded the entire exon 47 and was identical to the AAC24516 sequence and similar to a clone (AAW56205) isolated from mouse brain (Richards *et al.*, 2007). The second variant (TCA56, Fig. 1) lacked 213 nucleotides compared with TCA50. The deletion in TCA56 was different from the one found in CAJ09863 (Fig. 1) and produced a novel rat Cav2.1 variant. Both deletions were similar to those found in mouse Purkinje neurons (Tsunemi *et al.*, 2002), but due to frameshifts of the open reading frame, the amino acid sequences of the mouse variants differ substantially at the N- (BAB85612) or the C-terminus (BAB85611) of exon 47 (Fig. 1b). We constructed two cDNAs [Cav2.1(e47) and Cav2.1(e47s)] that encode the rat Cav2.1 subunit with full length exon 47 (i.e., TCA50) and the shorter variant (i.e., TCA56), respectively (Fig. 2a). When co-expressed with the Cav β 4a and Cav α 2 δ 1 subunits in *X. laevis* oocytes (Fig. 2b), Cav2.1, Cav2.1(e47) and Cav2.1(e47s) displayed globally similar electrophysiological properties (Fig. 2c and Table 1). The inactivation kinetics, estimated using the mean R400 values, were also comparable (Fig. 2c and Table 1). We obtained similar results when the three Cav2.1 variants were co-expressed with Cav β 1b or Cav β 2a that accelerates or decelerates inactivation, respectively, instead of Cav β 4a (Table 1). We next investigated the recovery from inactivation that is slower for the human long

Cav2.1 isoform compared with the short isoform (Adams *et al.*, 2009), but we did not observe this difference when using rat Cav2.1 and Cav2.1(e47) or Cav2.1(e47s) (Fig. 3).

3.2 The rat Cav2.1 transcripts produce C-terminal fragments in *X. laevis* oocytes

Human long Cav2.1 produces a C-terminal fragment (α 1ACT) when expressed in HEK or PC12 cells (Kubodera *et al.*, 2003; Kordasiewicz *et al.*, 2006; Ishiguro *et al.*, 2010). However, little is known about the Cav2.1 isoform with the shorter C-terminus and whether C-terminal fragments are produced when the channel is expressed in *X. laevis* oocytes. Therefore, we co-injected the Cav β 4 and Cav α 2 δ 1 subunits with rat Cav2.1-GFP, Cav2.1(e47)-GFP, or Cav2.1(e47s)-GFP in *X. laevis* oocytes and selected expressing oocytes. Western blot analysis with an anti-GFP antibody (Fig. 4a) showed the presence of full-length Cav α 1 (band above 250kDa) and of additional bands between 60-90kDa. This demonstrated that rat Cav2.1 produces C-terminal fragments, like human Cav2.1, independently of the presence of exon 47. These C-terminal fragments might influence the expression and electrophysiological properties of Cav2.1 channels. Indeed, it was previously shown that Cav β 4 interacts specifically with a C-terminus binding domain (SS2) in the rabbit Cav2.1 isoforms BI-1 and BI-2 (Walker *et al.*, 1999; Sandoz *et al.*, 2001). Therefore, we generated two Cav2.1 C-terminal fragments that start at residue I1907 (according to the AAA40806 sequence) and encompass the full-length exon 47 (CT1(e47)) or the C-terminal sequence of the Cav2.1 isoform without exon 47 (CT1) (Fig. 5a). We then expressed C-terminally GFP-tagged CT1 and CT1(e47) together with Cav β 4 in HEK293 cells. Co-immunoprecipitation assays of protein lysates showed that both CT1 and CT1(e47) interacted with Cav β 4 (Fig. 4b). These findings indicate that in *X. laevis* oocytes functional Cav2.1 channels coexist with C-terminal fragments, and that these fragments can interact with channel partners, such as Cav β 4a.

3.3 Over-expression of C-terminal fragments do not affect Cav2.1 expression and functional properties in *X. laevis* oocytes

To evaluate the functional role of the Cav2.1 C-terminus and the potential influence of the different C-terminal fragments, we also generated a rat Cav2.1 subunit that lacks the CT1 fragment (Cav2.1 Δ CT1, Fig. 5a). When co-expressed with Cav β 4 and Cav α 2 δ 1 in *X. laevis* oocytes, Cav2.1 Δ CT1 did not produce functional channels (Fig. 5b) even after co-expression of CT1 (not shown). Moreover, co-injection of Cav β 4 and Cav α 2 δ 1 with Cav2.1 and CT1 or CT1(e47) (1:1:1:1 molar ratio) did not, or marginally, affect the parameters of the current-voltage curves, of the inactivation curves, and the R400 values (Fig. 5c and Table 1). We confirmed the expression of the His-tagged C-terminal fragments in *X. laevis* oocytes by Western blot analysis after the recordings (Fig. 5d). As these fragments interact with the Cav β 4 subunit (see Fig. 4b), we tested whether they could inhibit Cav2.1 expression when injected in excess relative to the cDNA encoding Cav2.1, Cav β 4 and Cav α 2 δ 1 (molar ratio 1:1:1:5). However, the percentage of expressing oocytes was similar when Cav2.1 was expressed alone or with CT1 or CT1(e47) (44%, 43%, and 36%, respectively, four independent experiments) (Fig. 5e (left panel)), suggesting that the C-terminal fragments did not inhibit Cav2.1 expression by titrating the Cav β 4 subunit. We confirmed this lack of effect by systematically measuring the current amplitude in all the expressing oocytes in a single experiment. Indeed, we found similar mean current amplitude values for Cav2.1 expressed alone or with CT1 or CT1(e47) (Fig. 5e (right panel)). Cav2.1 voltage-dependent properties and inactivation kinetics also were not affected after injection in excess of C-terminal fragments (Table 1).

The effect of the co-expressed C-terminal fragments could have been hindered by the presence of the C-terminus in the Cav2.1 subunit. As CT1 deletion (Cav2.1 Δ CT1) affects functional expression, we introduced a stop codon after residue A2043 (according to the AAA40806 sequence) just before the SS2 binding domain (Cav2.1 Δ CT2, Fig. 6a). When co-expressed with Cav β 4a and Cav α 2 δ 1 in *X. laevis* oocytes, Cav2.1 Δ CT2 gave rise to functional channels (Fig. 6c). Moreover, Cav2.1 Δ CT2 electrophysiological properties were undistinguishable from those

of Cav2.1 (Fig. 6d and Table 1). Co-expression with CT2 or CT2(e47) (Fig. 6a) did not modify Cav2.1 Δ CT2 properties (Fig. 6d and Table 1). We confirmed CT2 and CT2(e47) expression in the recorded oocytes by Western blotting (Fig. 6b). These results suggest that the lack of effects of the C-terminal fragments observed with full-length Cav2.1 was not due to the presence of the C-terminus in Cav2.1.

4 DISCUSSION

In this study, we cloned Cav2.1(e47) and Cav2.1(e47s), two C-terminal variants of the rat Cav2.1 subunit that harbor the full length (TCA50) or a shorter variant (TCA56) of exon 47 (Fig. 1) respectively, and analyzed their functional properties after expression in *X. laevis* oocytes. Whatever the co-expressed Cav β subunit (Cav β 1b, Cav β 2a or Cav β 4a), the electrophysiological properties of Cav2.1(e47) and Cav2.1(e47s) were comparable to those of the short Cav2.1 isoform. Moreover, these three Cav2.1 isoforms produced C-terminal fragments, like the human *CACNA1A* gene. These fragments interacted with the Cav β 4a subunit in co-immunoprecipitation assays. However, overexpression of these C-terminal fragments with full length Cav2.1 did not modify the expression or the functional properties of the channel.

Exon 47 is present only in some Cav2.1 isoforms because the retention of the GGCAG sequence produces a frameshift of the reading frame (see Fig. 1). Based on our results, we can expect that exon 47 might be expressed in some isoforms of α 1ACT. Comparison of the different C-terminus variants among species highlights differences in the events leading to their production and also in their sequences. On the other hand, when expressed in HEK293 cells, the three mouse Cav2.1 variants (the short MPc, and the two MPI and MPPII variants) show similar electrophysiological properties (Tsunemi *et al.*, 2002). Although the C-terminal sequences of the mouse and rat variants are different, these results are consistent with our observations in *X. laevis* oocytes. The channel activation and inactivation processes are not affected by Cav2.1 variants with different C-terminal sequence (mouse MPI and MPPII, and rat Cav2.1(e47) and Cav2.1(e47s)). Similar results were obtained in a study that compared the properties of human Cav2.1 with or without extended C-terminus (fully translated exon 47 with 11 Q residues in the polyQ expansion) co-expressed in HEK293 cells with Cav β 4 (Adams *et al.*, 2009) or in another study that used human/mouse chimeric Cav2.1 channels also expressed in HEK293 cells

(human Cav2.1 sequence with murine exon 47) (Heck *et al.*, 2019). However, the recovery from inactivation was slower and inactivation accumulation was greater for the long than for the short Cav2.1 variant (Adams *et al.*, 2009). Although the rabbit BI-1 and BI-2 variants are quite different (the C terminus of the long isoform BI-2 harbors an additional Cav β binding site besides SS2) (Sandoz *et al.*, 2001), the functional properties of both subunits are very similar when expressed with Cav β 3 or Cav β 4. Indeed, the additional Cav β binding domain in BI-2 seems to affect only the current density (Sandoz *et al.*, 2001). The sequence of the Cav β 4 SS2 binding domain is well conserved among species, and our results show that rat Cav2.1 C-terminus binds to Cav β 4, as previously reported for the rabbit Cav2.1 subunit (Walker *et al.*, 1998; Sandoz *et al.*, 2001). However, the results obtained with Cav2.1 Δ CT2 (without the SS2 binding domain) seem to exclude a functional role for this interaction site when the channel is expressed at the plasma membrane. A similar deletion in a mouse Cav2.1 variant did not affect expression or functional properties when expressed at the calyx of Held in a knock-in mouse model (Lübbert *et al.*, 2017).

In the majority of the central nervous system synapses, P/Q-type calcium channels are the principal Ca²⁺ channels that trigger the neurotransmitter release. This results from specific interactions between the Cav2.1 subunit and several scaffold proteins that mediate the link between Ca²⁺ channels, synaptic vesicles, and the exocytosis machinery. Indeed, in Cav2.1, the cytoplasmic loop that links domains II and III contains a synprint interaction domain for the interaction with synaptic proteins, such as syntaxin-1 and synaptotagmin (Rettig *et al.*, 1996; Charvin *et al.*, 1997). This domain is also found in the Cav2.2 subunit that encodes the N-type Ca²⁺ channel, involved in neurotransmission. Interestingly, a Cav2.2 variant in which the synprint domain is missing has been identified in the human brain (Kaneko *et al.*, 2002). Other sites for the interactions with RIM, MINT1, Rim Binding Proteins and CASK, important for the synaptic localization of the Cav2.1 subunit, are localized in Cav α C-terminus (Maximov *et*

al., 1999; Hibino *et al.*, 2002; Kaeser *et al.*, 2011). The relative importance of each of these interactions for Cav2.1 targeting to the presynaptic active zone is a matter of debate (Lübbert *et al.*, 2017), but it is interesting that some of these binding sites are encoded by exon 47, and are therefore not found in all Cav2.1 variants (Hirano *et al.*, 2017). In a recent study, Heck and colleagues found that the different release probability and short-term plasticity of hippocampal synapses that express Cav2.1 with or without exon 47 are due to a difference in surface mobility between these channels (Heck *et al.*, 2019). It is tempting to speculate that Cav2.1 isoforms with different exon 47 variants might specifically modulate these properties.

In conclusion, our results exclude a functional role of the C-terminal fragments on Cav2.1 expression level and electrophysiological properties when expressed in *X. laevis* oocytes. Therefore, we could hypothesize that Cav2.1 C-terminus is mainly involved in Cav2.1 trafficking to specific cellular compartments. Moreover, we found that the C-terminal fragments produced by the Cav2.1 transcripts may contain different splice variants, especially in exon 47 sequence. These fragments, produced thanks to the presence of an IRES, regulate the expression of specific genes (Du *et al.*, 2013). Interestingly, the pathological pQ expansion found in patients with SCA6 abolishes the transcriptional activity of $\alpha 1$ ACT. Thus, the transcriptional roles of the C-terminal fragments in mouse, rat and rabbit Cav2.1, or of human Cav2.1 without pQ expansion but with a specific C-terminal sequence need to be investigated.

ACKNOWLEDGEMENTS

The authors wish to acknowledge the Centre National de la Recherche Scientifique, the Institut National de la Santé et de la Recherche Médicale and the Université de Montpellier for their financial support. T.C. wishes to acknowledge Naouel Ougouti for her implication at the beginning of this work.

COMPETING INTERESTS

The authors declare no competing interest.

AUTHORS' CONTRIBUTIONS

TC designed the study, performed the molecular biology and the electrophysiological experiments, analyzed the results and wrote most of the paper. TC and CM did the Western blotting and the co-immunoprecipitation experiments. PC, MR and MV provided guidance and support, and critically reviewed the manuscript.

DATA ACCESSIBILITY

The authors confirm that all data that led to the findings are available and will be shared with the research community upon request to the corresponding author. Please direct all email requests to thierry.cens@inserm.fr.

ABBREVIATIONS

polyQ – tract of glutamine residues

IRES – internal ribosome entry site

SCA6 – spinocerebellar ataxia type 6

X. laevis – *Xenopus laevis*

Table 1: Parameters of the voltage-current curves and of the inactivation curves, and R400 values for all the subunit combinations (Cav α 2 δ 1 was always present). Data are the mean $\pm$ S.E.M. of n oocytes. Statistical significance (p values using Student's t test) vs Cav2.1 β 4, p ; vs Cav2.1 β 1b, $*p$; vs Cav2.1 β 2a, $**p$; vs Cav2.1 Δ C2 β 4, $***p$, is given for all parameters.

FIGURE CAPTIONS

Figure 1. Summary of the events leading to the expression of Cav2.1 isoforms with different C-terminus sequences in the rat and mouse. (a) The use of an alternative acceptor site at the exon 46-47 boundary allows the insertion of the GGCAG sequence at the beginning of exon 47 and the in-frame translation of exon 47, leading to Cav2.1 isoforms with full-length or deleted exon 47 in the rat (AAC24516, TCA50, CAJ09863, TCA56) and mouse (AAW56205, BAB85612, BAB85611). Conversely, omission of the GGCAG sequence causes a frameshift, leading to a stop codon at the beginning of exon 47 (AAC52940, AAC40806) (b) Alignment of the amino acid sequences of the extended C-terminus of rat and mouse Cav2.1.

Figure 2. The short and the two long rat Cav2.1 variants show similar functional properties. (a) Schematic representation of the three rat Cav2.1, Cav2.1(e47) and Cav2.1(e47s) variants that differ at the C-terminus. The arrow indicates where the translation of human $\alpha 1$ ACT begins (M₁₉₁₁). (b) Representative current traces recorded from *X. laevis* oocytes that express the indicated Cav α subunit together with Cav β 4a and Cav α 2 δ 1. Currents were elicited by 400ms-long step depolarizations from a holding potential of -100 mV to potentials between -60 mV and +40 mV. Scale bars, 500 nA. (c) Current voltage curves (left), isochronal inactivation curves (middle), and R400 values (right) obtained for Cav2.1, Cav2.1(e47) and Cav2.1(e47s) in *X. laevis* oocytes that express the indicated Cav α subunit together with Cav β 4a and Cav α 2 δ 1. The parameters of both curves and the R400 values are similar or marginally affected (see Table 1). n.s = non-significant.

Figure 3. The rat Cav2.1, Cav2.1(e47) and Cav2.1(e47s) variants exhibit similar recovery from inactivation. (a) Representative current traces obtained in *X. laevis* oocytes that co-express the indicated Cav2.1 variants with Cav β 4a and Cav α 2 δ 1. The experimental protocol is described

above the traces. Depolarization to +10 mV for 5 s precedes a second 100ms-long depolarization to +10 mV after inter-pulse intervals between 100 ms and 8 s. Scale bar, 500 nA.

(b) Percentage of current recovery plotted against the inter-pulse duration for the three variants.

(c) The percentage of current recovery after 8 s of Cav2.1 is significantly smaller than that of Cav2.1(e47) ($86 \pm 1 \%$, $n = 9$ and $89 \pm 1 \%$, $n = 10$, respectively; $p = 0.0036$) and is similar to that of Cav2.1(e47s) ($85 \pm 1 \%$, $n = 6$; $p = 0.49$). n.s = non-significant.

Figure 4. Rat Cav2.1 variants produce C-terminal fragments that interact with Cav β 4a. (a) Western blot (WB) analysis of lysates from *X. laevis* oocytes that express Cav2.1, Cav2.1(e47) or Cav2.1(e47s) together with Cav β 4 and Cav α 2 δ 1. The Cav α subunits were detected with an anti-GFP antibody (top), while Cav β 4a was detected with a specific anti-Cav β 4 antibody (bottom). The expected molecular masses were 58, 278, 294 and 287 kDa for Cav β 4a, Cav2.1-GFP, Cav2.1(e47)-GFP and Cav2.1(e47s)-GFP, respectively. The three variants produce C-terminal fragments with an apparent molecular mass between 60 and 100 kDa, depending on the size of the Cav α C-terminus. Doublets (asterisks) are due to GFP (see also Fig. 4b) and disappear when using the 6His tag (see Fig. 5d). NI, lysate obtained from non-injected oocytes. (b) Co-immunoprecipitation assays using protein lysates from HEK293 cells transfected with CT1-GFP or CT1(e47)-GFP alone or with Cav β 4a show the physical interaction of the Cav β 4 with both C-terminal fragments. The expected molecular masses were 64 and 80 kDa for CT1-GFP and CT1(e47)-GFP, respectively.

Figure 5. Over-expression of C-terminal fragments does not affect Cav2.1 expression and functional properties. (a) Schematic representation of the deleted Cav2.1 (Cav2.1 Δ CT1), and the short (CT1) and the long (CT1(e47)) C-terminal fragments. (b) Representative current traces recorded from *X. laevis* oocytes injected with the indicated Cav α subunit, Cav β 4a and

Cav α 2 δ 1, alone or with the short or the long C-terminal fragment tagged with 6His at the C-terminus (1:1:1:1 molar ratio). Currents were elicited by 400ms-long step depolarizations from a holding potential of -100 mV to potentials between -60 mV and +40 mV. Scale bars, 500 nA.

(c) Current voltage curves (left), isochronal inactivation curves (middle), and R400 values (right) obtained for Cav2.1 alone, or with the short or the long C-terminal fragment. The parameters of both curves and the R400 values are similar or marginally affected (see Table 1).

(d) Western blot analysis of lysates from *X. laevis* oocytes injected with Cav2.1 alone (H₂O), or with CT1-6His or CT1(e47)-6His and collected after recordings. The expected molecular masses were 38 and 54 kDa for CT1-6His and CT1(e47)-6His, respectively. NI, lysate obtained from non-injected oocytes.

(e) Percentage of expressing oocytes in four independent experiments (right) and mean amplitude of the currents recorded from all the expressing oocytes in one of these four experiments (left). Oocytes were injected with Cav2.1, Cav β 4a and Cav α 2 δ 1 alone, or with the short or the long C-terminal fragment (1:1:1:5 molar ratio), and recording performed two days later. The mean amplitude currents measured for Cav2.1 alone (1255 ± 176 nA, $n = 19$), with CT1 (1249 ± 122 nA, $n = 11$) or with CT1(e47) (1263 ± 177 nA, $n = 18$) were similar ($p = 0.98$ and $p = 0.99$, respectively). n.s = non-significant.

Figure 6. Deletion of the Cav β binding domain in Cav2.1 C-terminus does not affect Cav2.1 functional properties. (a) Schematic representation of Cav2.1 Δ CT2 and the C-terminal fragments CT2 and CT2(e47). (b) Western blot analysis of lysates from *X. laevis* oocytes expressing Cav2.1 alone (H₂O) or with CT2-6His or CT2(e47)-6His. The expected molecular masses were 22 kDa and 39 kDa for CT2-6His and CT2(e47)-6His, respectively. NI, lysate obtained from non-injected oocytes. (c) Representative current traces recorded from *X. laevis* oocytes injected with the indicated Cav α subunit with Cav β 4a and Cav α 2 δ 1, alone or with CT2 or CT2(e47) (1:1:1:1 molar ratio). Currents were elicited by 400ms-long step depolarizations

from a holding potential of -100 mV to potentials between -60 mV and +40 mV. Scale bars, 500 nA. (d) Current voltage curves (left), isochronal inactivation curves (middle), and R400 values (right) obtained for Cav2.1 alone, or with CT2-6His or CT2(e47)-6His. The parameters of both curves and the R400 values are similar or marginally affected (see Table 1).
