INTRODUCTION

This paper deals with a combinatorial problem arising from studies in distributed and parallel architectures. The interconnection network is the heart of parallel computers, and several topologies have been proposed (see [1], [2], [16]). One of the most used is the loop topology, due to its simplicity [13]; in this case, the network consists of a loop (directed or not), which is modeled by a cycle (directed or not). But the simple loop topology has some disadvantages, in particular, its high vulnerability and low performance. Indeed, the network does not work after the failure of one node or arc (in the directed case) or two nodes or edges (in the undirected case). Furthermore, the diameter of the loop network, which corresponds to the maximum transmission delay, is $n - 1$ (in the directed case) or $\left\lfloor \frac{n}{2} \right\rfloor$ (in the undirected case).

A simple way to improve the performance of the network is to increase its connectivity and decrease its diameter. That can be done by adding links. However, for cost and design reasons (in particular there can only be a limited number of links leaving a node), one wants to add only a few links in each node. Furthermore, to maintain easy routings and implement distributed algorithms, the addition of these links must be done in a symmetric (or homogeneous) way.

Different "loop networks" (i.e., networks representable by Hamiltonian graphs or digraphs) have been proposed. We refer the reader to the recent survey of Bermond, Comellas, and Hsu [4] and its references.

Note that if one only wants to find a network with a limited degree and a good diameter, one can choose the de Bruijn or Kautz digraphs. Indeed these digraphs have outdegree and indegree d , d^D or $d^D + d^{D-1}$ vertices, and diameter D . They can be considered as iterated line digraphs of the complete digraphs with or without loops. Therefore, being line digraphs of Eulerian digraphs, these graphs are Hamiltonian. Generalizations of these digraphs for any value of n have been considered by different authors, and recently Du, Hsu, Hwang, Zhang [8] and Du and Hwang [9] proved that these generalized digraphs are Hamiltonian except when the out- and indegree is 2 and n is odd. However, in the case $d = 2$, a class of networks obtained by modifying the generalized Kautz digraphs has been proposed by Du, Hsu, and Hwang [7]. In summary, there exist, for any d and n , digraphs of order n , indegree

and outdegree d , which are Hamiltonian and have a diameter roughly equal to $\lceil \log_2 n \rceil$. These digraphs have the best possible connectivity (mainly d or $d - 1$). For results on the vulnerability of these digraphs, see the survey of Bermond, Homobono, and Peyrat [3].

If one also wants some strong symmetry properties, one can consider multiple-step digraphs or graphs. Let us denote by $G(n; s_1, s_2, \dots, s_k)$ the k fixed-step digraph, with n vertices labeled with the integers modulo n , and such that there is an arc from node i to the k nodes $i + s_1, i + s_2, \dots, i + s_k$. The problem of determining the minimum of the diameter of these k fixed-step digraphs among all the possible choices for $s_1, s_2, \dots, s_k$ is far from being solved, although important results have been obtained, particularly when s_1 is fixed to 1 (see the survey in [4]). For example, in the case of double fixed-step digraphs $G(n; s_1, s_2)$ the diameter is at least $\lceil \sqrt{3n} \rceil - 2$ (see [15]). Infinite families of values of n for which this bound may be achieved have been exhibited (Erdős and Hsu [10], Fiol, Yebra, Alegre, and Valero [11], Hwang and Xu [12]), but the exact value of the minimum diameter of the double fixed-step digraphs is still generally unknown. Mean distance and vulnerability problems have also been considered.

Here, we restrict our attention to the undirected case where the k fixed-step graph $G(n; \pm s_1, \pm s_2, \dots, \pm s_k)$ is the graph such that there is an edge between the node i and the nodes $i \pm s_1, \dots, i \pm s_k$. We deal mainly with the case of double fixed-step graphs. We determine the exact value of the minimum diameter for all values of n . We also determine the minimum mean distance, and study the vulnerability of these graphs. The problem of determining their diameter was first considered by Wong and Coppersmith [15]. If the undirected case has received less attention than digraphs in the context of loop networks, they have, however, been well studied in graph theory as "circulant graphs" or particular cases of "Cayley graphs."

The results were obtained in 1984 and presented at the conference in New York (June 1985). At this conference, Hsu informed us that the results concerning the diameter have also been independently obtained by Boesch and Wang [6]. They have also been independently obtained by Yebra, Fiol, Morillo, and Alegre [17].

DOUBLE-LOOP GRAPHS

Here we consider undirected double fixed-step loop networks. Such networks are modeled by undirected graphs with n vertices labeled with the integers modulo n . Let a and b be two integers between 1 and $(n - 1)/2$. Then every vertex i is joined by an edge to the vertices $i \pm a$ and $i \pm b$ (modulo n).

We will call such a graph a "double-loop graph" and denote it by $DLG(n; a, b)$. Let us note that these graphs are also known as circulant graphs and can be seen as Cayley graphs associated to the group of the integers modulo n . FIGURE 1 shows $DLG(11; 2, 3)$.

The following two propositions are easy:

PROPOSITION 1: $DLG(n; a, b)$ is regular of degree 4.

FIGURE 1.

PROPOSITION 2: $DLG(n; a, b)$ is connected if and only if $\gcd(a, b, n) = 1$ (where $\gcd(a, b, n)$ denotes the greatest common divisor of a, b , and n).

The following theorem is a particular case of a theorem obtained independently by different authors saying that any connected Cayley graph on an Abelian group is Hamiltonian (see the survey of Witte and Gallian [14]).

PROPOSITION 3 [see 14]: If $\gcd(a, b, n) = 1$, then $DLG(n; a, b)$ is Hamiltonian.

That shows that if $DLG(n; a, b)$ is connected, then it is a loop network. In fact, a stronger result has been proved by Bermond, Favaron, and Maheo [5]. It follows that these graphs can be seen as the union of two edge disjoint loops and that each loop can be used for different purposes of transmission of the messages. This result was conjectured in an earlier version of this paper and justifies the terminology "double-loop graphs."

PROPOSITION 4 [5]: If $\gcd(a, b, n) = 1$, then $DLG(n; a, b)$ can be decomposed into two Hamiltonian cycles.

DIAMETER

The distance $d(x, y)$ between two vertices x and y is the length of a shortest x - y path. The diameter D of a graph is the maximum distance over all the pairs of vertices.

$$D = \max_{(x, y) \in V \times V} d(x, y).$$

The mean distance $\bar{D}$ is equal to

$$\bar{D} = \frac{1}{n(n-1)} \sum_{(x,y) \in V \times V} d(x,y).$$

A double-loop graph being vertex transitive, if the vertices are labeled by $0, 1, \dots, n-1$:

$$D = \max_{1 \leq i \leq n-1} d(0, i)$$

and

$$\bar{D} = \frac{1}{n-1} \sum_{1 \leq i \leq n-1} d(0, i).$$

The optimization problem considered in the Introduction consists in finding a and b that minimize D and $\bar{D}$, for a given n . This problem was already considered by Wong and Coppersmith [15] in the case $a = 1$. In the general case it has also been considered by Yebra, Fiol, Morillo, and Alegre [17] and by Boesch and Wang [6], who studied circulant graphs with minimum diameter.

Following Fiol, Yebra, Alegre and Valero [11] and Yebra, Fiol, Morillo, and Alegre [17], we can visualize the problem in a geometric manner. We will represent the edge $(i, i+a)$ by a horizontal segment and the edge $(i, i+b)$ by a vertical one. The distance between two points is obtained by adding the number of horizontal and vertical segments. FIGURE 2 shows the vertices obtained at a distance of at most k of the vertex 0. In this geometric context, the problem consists in finding a tile consisting of n unit squares that tessellates periodically the plane and to find a and b such that the n unit squares of the tile are numbered from 0 to $n-1$ (see FIG. 3 for such a realization with $n = 13$, $a = 2$, $b = 3$).

First let us consider the related optimization problem of finding the maximum order of a double-loop graph of given diameter k .

The first theorem can be found in [6], [15], and [17]. Here we repeat the proof, in order to be complete.

THEOREM 1: The maximum order of a double-loop graph of diameter k is $2k^2 + 2k + 1$.

FIGURE 2.

FIGURE 3.

Proof: The vertices at distance j from the vertex 0 are $\pm ja, \dots, \pm(j-i)a \pm ib, \dots, \pm jb$ (with $0 \leq i \leq j$), and the maximum number of such vertices is $4j$. Therefore, the maximum number of vertices of the graph is at most

$$1 + \sum_{j=1}^k 4j = 2k^2 + 2k + 1. \quad \square$$

The following theorem shows that the bound is attained (the result has also been obtained independently by Boesch and Wang [6] and Yebra, Fiol, Morillo, and Alegre [17]). We furthermore determine all the possible sets of values for a and b .

THEOREM 2: There exists a $\text{DLG}(2k^2 + 2k + 1; a, b)$ of diameter k if and only if $a \equiv kp$ and $b \equiv (k+1)p$, where p is any integer less than n that is relatively prime with n .

Proof: The fact that the bound is attained with $a = k, b = k+1$ follows either from arithmetical conditions or from a geometrical point of view: for example, one can check that all the vertices at distance at most k from 0 are all the integers between $-k(k+1)$ and $k(k+1)$, which, modulo $2k^2 + 2k + 1$, are exactly all the elements. Geometrically, one can see that the integers in a tile are ranged enumeratively in a diagonal SE-NW, and that this tile (in the form of a cross) tessellates the plane.

The determination of all the values of a and b such that $\text{DLG}(2k^2 + 2k + 1; a, b)$ has diameter k is implicitly contained in [17] and follows from geometrical considerations. Indeed we must have:

$$(k+1)a - kb \equiv 0 \pmod{n}$$

$$ka + (k+1)b \equiv 0 \pmod{n}.$$

As the determinant is congruent to 0 modulo n , this system has nontrivial solutions that are of the form $a \equiv kp$ and $b \equiv (k+1)p$, where p and n are relatively prime to assure that the graph is connected. $\square$

FIGURE 4.

Now let us come back to the original problem of determining the minimum diameter of $DLG(n; a, b)$. The following theorem has also been obtained by Boesch and Wang [6]. It says that the minimum diameter is

$$k_0 = \left\lfloor \frac{1 + \sqrt{2n-3}}{2} \right\rfloor = \left\lceil \frac{-1 + \sqrt{2n-1}}{2} \right\rceil.$$

THEOREM 3: If $2(k-1)^2 + 2(k-1) + 1 < n \leq 2k^2 + 2k + 1$, then the minimum diameter of $DLG(n; a, b)$ is k , and the bound is achieved with $a = k$ and $b = k + 1$.

Proof: By Theorem 1 the diameter is at least k . Furthermore, as we have seen in the proof of Theorem 1, the vertices at a distance of at most k are all the integers between $-k(k+1)$ and $k(k+1)$, and therefore all the integers modulo n as $n \leq 2k^2 + 2k + 1$. This fact is also illustrated geometrically. Indeed the tiles obtained by deleting unit squares on the diagonal also tessellate the plane (see FIGS. 4 and 5 for $n = 12, 11$). $\square$

REMARK: The determination of all the values a and b such that the diameter of $DLG(n; a, b)$ is minimum for a given n in the preceding interval is an open problem.

FIGURE 5.

At present the minimum diameter of $DLG(n; 1, b)$ is not known. This was the original problem of Wong and Coppersmith [15]. Partial results have recently been obtained by Bermond and Tzvieli [5], Du, Hsu, Li, and Xu [8], and Tzvieli [13]. Another set of values that will be useful to compute the mean distance is given in the following theorem.

THEOREM 4: If $2(k-1)^2 + 2(k-1) + 1 < n \leq 2k^2 + 1$, then the diameter of $DLG(n; k-1, k)$ is k .

Proof: By Theorem 3, all the vertices i such that $|i| \leq k^2 - k$ are at a distance of at most $k-1$. It suffices to prove that the remaining vertices are at a distance of at most k . That follows from the fact that a vertex i is adjacent to vertices $i \pm k$, and therefore the neighborhoods of the vertices i such that $|i| \leq k^2 - k$ contain all the vertices j such that $|j| \leq k^2$. $\square$

MEAN DISTANCE

THEOREM 5: The mean distance of a double-loop graph of order n is at least $\bar{k}_0$ with

$$\bar{k}_0 = k_0 \left(1 - \frac{2k_0^2 - 2}{3(n-1)} \right)$$

where

$$k_0 = \left\lfloor \frac{1 + \sqrt{2n-3}}{2} \right\rfloor.$$

This bound is attained for every n by considering $\text{DLG}(n; a, b)$ with $b = a + 1$ and $a = k_0$ or $k_0 - 1$.

Proof: Recall that $(n-1)\bar{D} = \sum_{i \leq n-1} d(0, i)$ and that we have at most $4j$ vertices at distance j from the vertex 0. Therefore:

$$(n-1)\bar{D} \geq 4 \sum_{j=1}^{k_0-1} j^2 + k_0(n - (2k_0^2 - 2k_0 + 1))$$

$$(n-1)\bar{D} \geq (n-1)k_0 - \frac{2k_0^3 - 2k_0}{3}$$

therefore $\bar{D} \geq \bar{k}_0$. To show that the bound is attained, we will distinguish two (nondisjoint) cases:

Case 1: $n \geq 2k_0^2 - 1$. Consider $\text{DLG}(n; k_0, k_0 + 1)$. The vertices i such that $|i| \geq k_0^2$ are at a distance of at least k_0 , and therefore (by Theorem 2) k_0 from the vertex 0. Therefore, as $n \geq 2k_0^2 - 1$ the distribution of the vertices at distance j , with $j < k_0$, from the vertex 0 is the same as in $\text{DLG}(2k_0^2 + 2k_0 + 1; k_0, k_0 + 1)$ and we have exactly $4j$ vertices at distance j for $j < k_0$ and the remaining vertices at distance k_0 , which is the optimal configuration.

Case 2: $n \leq 2k_0^2 + 1$. Consider $\text{DLG}(n; k_0 - 1, k_0)$. By Theorem 1, all the vertices i such that $|i| \leq k_0^2 - k_0$ are at a distance of at most $k_0 - 1$, and there are

FIGURE 6.

FIGURE 7.

exactly $4j$ vertices at distance j from the vertex 0 with $j \leq k_0 - 1$. The other vertices are at distance k_0 by Theorem 4. $\square$

REMARK 1: Asymptotically the mean distance is $\sqrt{2n/3}$.

REMARK 2: Geometrically the proof means that if $n > 2k_0^2 - 1$, the tile corresponding to $\text{DLG}(n; k_0, k_0 + 1)$ is obtained by deleting unit squares of the extremal diagonals (that correspond to vertices at distance k_0) of $\text{DLG}(2k_0^2 + 2k_0 + 1; k_0, k_0 + 1)$ (FIG. 6, $n = 17$). Similarly for $n \leq 2k_0^2 + 1$, the tile is obtained by adding unit squares in the neighborhood of the extremal diagonals of the tile associated to $\text{DLG}(2k_0^2 - 2k_0 + 1; k_0 - 1, k_0)$ (see FIG. 7, $n = 19$).

ROUTING

The routing in the graph $\text{DLG}(n; k, k + 1)$ is very simple. To find a shortest path between i and j , it suffices to determine p and q such that $j - i = pk + q(k + 1)$ with p, q integers and $|p| + |q|$ the smallest possible. Then there exists $\binom{|p| + |q|}{|p|}$ shortest paths from i to j consisting of $|p|$ steps of the kind k , and $|q|$ steps of the kind $k + 1$.

VULNERABILITY

Boesch and Wang [6, theorem 5] proved that a $\text{DLG}(n; k_0, k_0 + 1)$ has connectivity 4. Here we study the effect of the deletion of a vertex (or an edge) on the diameter.

THEOREM 6: The diameter of the graph obtained by deleting one vertex or one edge in $\text{DLG}(n; k_0, k_0 + 1)$ is at most $k_0 + 1$.

Proof: As we have seen for the routing, there are $\binom{|p| + |q|}{|p|}$ shortest paths between vertices i and j . Therefore, after deletion of one vertex s or one edge e , the

distance can increase only if all the shortest paths contained this vertex or edge. This implies that $p = 0$ or $q = 0$, and that the vertex (or edge) deleted is in the path. Furthermore, if the vertex s deleted belongs to such a path $s - h, s, s + h$ (with $|h| = k_0$ or $k_0 + 1$), we can replace it by the subpath $s - h, s - h + h', s + h', s + h' + h, s + h$, with $h' = k_0$ or $k_0 + 1$ according $|h| = k_0$ or $k_0 + 1$. Similarly, we can replace the edge $s, s + h$ by the subpath $s, s + h', s + h' + h, s + h$. In any case, the distance can increase at most by 2. Therefore, to prove that the diameter of $DLG(k_0, k_0 + 1)$ is at most $k_0 + 1$, it suffices to prove that there exists a path of length $k_0 + 1$ between two vertices i and j such that $j - i = \pm k_0^2$ or $\pm(k_0^2 + k_0)$. If $j - i = \pm k_0^2$, such a path consists in k_0 edges with step $\pm(k_0 + 1)$ and one edge with step $\mp k_0$; indeed, $k_0^2 = k_0(k_0 + 1) - k_0$. Similarly, if $j - i = \pm(k_0^2 + k_0)$, it suffices to take $k_0 + 1$ edges with step $\pm k_0$. $\square$

REMARK: The diameter can be $k_0 + 1$ or k_0 . For example, in $DLG(18; 3, 4)$, there are two disjoint paths of length ≤ 3 between any pair of vertices, but in $DLG(19; 3, 4)$, there is only one path of length ≤ 3 between 0 and 6.

OPEN PROBLEM

One can ask for similar problems with multiple loops instead of double loops. But, even in the case of three loops there exists no perfect optimal solution. The determination of the minimum diameter might be a difficult problem. In that case, it follows from a result of Wong and Coppersmith [15] (see also [6]) that the minimum diameter $d(n)$ of a triple fixed loop graph $G(n; \pm a, \pm b, \pm c)$ satisfies $f(n) \leq d(n) \leq g(n)$, where $f(n)$ is of order $(3n/4)^{1/3}$ and $g(n)$ is of order $(27n/8)^{1/3}$. Recently, Peyrat has shown that $g(n)$ may be reduced to a function of order $(9n/8)^{1/3}$.

Recent results have recently been obtained on the determination of the minimum diameter of $DLG(n; 1, b)$ by Bermond and Tzvieli [5], Du, Hsu, Li, and Xu [8], and Tzvieli [13].
