Introduction

Computed tomography scan is a medical imaging technique using low doses of X-rays. It is commonly used for head and neck exploration of children. Repeated use of computed tomography scan can lead to a relatively high cumulative dose. Long-term effects of brain exposure, at low to moderate doses (≤ 2 Gy) of ionizing radiation on cognitive functions, such as learning and memory processes, are not well established and is a important scientific issue.

Among brain structures potentially impacted by irradiation, hippocampus is a structure of interest because of its involvement in spatial learning and memory processes. In the hippocampus, new neurons are continuously generated in the subgranular zone of the dentate gyrus during postnatal and adult life which makes it a potentially sensitive structure to X-rays.

Objectives

To study the impact of postnatal irradiation at low-to moderate doses thanks to two models of exposure
- Whole Brain vs Dorsal Dentate Gyrus → on spatial learning and memory
- on hippocampal adult neurogenesis

Experimental strategy

1. Irradiation procedure: Two models of exposure

   The irradiations are performed on the SARRP (Small Animal Radiation Research Platform, Xstrahl, Ltd., UK). (technical characteristics: high tension: 220V, intensity: 30 Gy)

   Control mice underwent scanner imaging like the other mice.

   Treatment plan:
   - Effective energy = 69 keV
   - Dose rate = 0.3 Gy/min
   - Dose applied: 0.25, 0.5, 1 or 2 Gy

   Whole Brain
   - Scanner image
   - MRI image

   Dorsal Dentate Gyrus
   - Scanner image
   - MRI image

   Superposition

   BrdU injections (2 x 150 mg/kg or 5 x 30 mg/kg)

2. Behavioral test

3. Immunofluorescence

   t₀ + 24 hours
   - BrdU + DCX / NeuN

   t₀ + 38 days
   - Density of immature neurons (BrdU/NeuN), 38 days after injection in the DGG (x̄ ± SD, n = 4, p < 0.05)
   - Density of mature neurons (BrdU/NeuN), 38 days after injection in the DGG (x̄ ± SD, n = 4, p < 0.05)

   t₀ + 10 days
   - Massed learning
   - Long-term spatial memory

   No impairment
   - No impairment
   - Impairment 1 Gy

Results

Spatial learning and memory

2. Massed learning

   10 days
   - 2 trials of 5 min / trial
   - Submerged Platform

Long-term spatial memory

   Total distance in the target quadrant (%)

   Control
   - 0.25 Gy
   - 0.5 Gy
   - 1 Gy
   - 2 Gy

   No impairment
   - Impairment

3. Adult neurogenesis processes: Focus on the dose of 1 Gy

   BrdU injections
   - 1 Gy
   - 10 days old
   - t₀

   Immunofluorescence
   - BrdU + DCX / NeuN

   t₀ + 24 hours
   - Density of immature neurons (BrdU/NeuN), 24 hours after injection in the DGG (x̄ ± SD, n = 4, p < 0.05)

   t₀ + 38 days
   - Density of mature neurons (BrdU/NeuN), 38 days after injection in the DGG (x̄ ± SD, n = 4, p < 0.05)

Discussion and perspectives

An exposure at the postnatal stage can induce detrimental consequences 3 months later.

The effects of X-rays at low-to moderate doses (0.25 to 2 Gy) on spatial memory are not linear after targeted exposure. Spatial memory impairment observed between our two mouse models, exposed at the dose of 1 Gy, could partially be explained by selective alterations in hippocampal adult neurogenesis.

However, it will be necessary to explore the different steps of adult neurogenesis more precisely. The inflammatory response will also be evaluated in parallel.
