HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

THE PROBLEM:

- Conventional storage devices can endure for 5-10 years
- 80% of data is cold (very rarely accessed)
- High cost of reliable storage

THE SOLUTION: Use of DNA as a means of digital data storage

- Longevity
- High capacity

→ Need for efficient encoding to control the cost of DNA synthesis!

PURPOSE OF THIS WORK:

- To propose a new efficient method for the encoding of images into DNA using **Vector quantization (VQ)** improving the results obtained in our previous work** while **controlling the DNA synthesis cost**.

THE PROPOSED METHOD:

- DWT** decomposition to reduce spatial redundancy
- VQ** to encode each DWT subband
- Closed loop **source allocation** to optimally compress an image

1

EXPERIMENTAL RESULTS:

- Image: Lena 512x512
- Training set of different face images to obtain the vectors
- NP: No Patterns → $L = 2K$
- 80% of L used: $K=80\% L$
- Results using VQ show great improvement compared to the results obtained in our previous work

** Dimopoulou, Melpomeni, et al. "A biologically constrained encoding solution for long-term storage of images onto synthetic DNA." 2019 27th European Signal Processing Conference (EUSIPCO). IEEE, 2019.

NUCLEOTIDE ALLOCATION:**Goal:**

For a desired rate R_t , find optimal values of k (number of vectors) and n (length of vectors) for VQ that minimizes the distortion.

For each DWT subband:

- Build Rate-Distortion curve for different k and n
- Optimal points are lying on the convex hull

5' TGAAG TTGAA GCATA TGATG ACTCT GATCG AGCTC GTCGG TGCTT TGACT CTGAA TAAGC CTTCT TATAG 3'

Example of an oligo where $k=L$ (top oligo) and an oligo where $L=2K$ (bottom oligo).

The two ways for treating patterns. (1) on the left and (2) on the right

5

BIOLOGICAL CONSTRAINTS ON THE ENCODING:

(Reduction of sequencing error)

- No homopolymers
- $\%G,C \leq \%A,T$
- No repetition of short patterns

BUILDING A RESTRICTED QUATERNARY CODE:

Two dictionaries of pair elements:

- $C_1 = \{AT, AC, AG, TA, TC, TG, CA, CT, GA, GT\}$
→ n picks: $L = 10^n$ codewords of length $l=n*2$
- $C_2 = \{A, T, C, G\}$
→ adding a symbol from C_2 at the end of codewords: $L = 10^n * 4$

- Codewords of an **even length** l are built by picking $n = l/2$ pair-elements from C_1
- Codewords of **odd length** l codewords are built by picking $n = (l-1)/2$ pair-elements from C_1 and adding a pair element from C_2 at the end

3

PATTERN REPETITIONS:

- VQ: efficient for compression
- More subband coefficients will be represented by the same vector
- Neighboring coefficients will be encoded to the same codeword → **pattern repetitions!**

Solution:

Increase code size L to allow double representation

MAPPING:

- To avoid patterns we need: $L \geq K$
- Mapping $\Gamma: \Sigma \rightarrow C^*$
- $m = \lfloor L/K \rfloor$
- $\Gamma(\hat{x}^i) = C^*(i + \text{rand}(0, m-1) * K)$

Two ways to treat pattern repetition:

- If $K < L \leq 2K$: double representation of most frequent symbols, $m=1$ (left image)
- If $L \geq 2K$: double representation of every word, $m=2$ (right image)
