### ABSTRACT

Acquisition of time knowledge (TK; the correct representation and use of time units) is linked to the development of numerical abilities, but this relationship has not been investigated in children. The current study examined the acquisition of TK and its association with numerical skills. A total of 105 children aged 6 to 11 years were interviewed with our Time Knowledge Questionnaire (TKQ), developed for purposes of this study, and the Zareki-R, a battery for the evaluation of number processing and mental calculation. The TKQ assessed conventional time knowledge (temporal orientation, temporal sequences, relationships between time units, and telling the time on a clock), estimation of longer durations related to birthday and life span, and estimation of the duration of the interview. Time knowledge increased with age, especially from 6 to 8 years, and was strongly linked to numerical skills. Regression analyses showed that four numerical components were implicated in TK: academic knowledge of numbers and number facts (e.g., reading Arabic numerals, mental calculation), number line estimation (e.g., correspondence between a number and a distance), contextual estimation (e.g., many/few leaves on a tree, children in a family), and numerical tasks involving verbal working memory (e.g., comparison of numbers presented orally). Numerical correlations with TK varied according to children's age; subtests based on academic knowledge of numbers, working memory, and number line estimation were linked with TK in the

## Introduction

Many philosophers have explored the relationship between time and number—from Aristotle (384–322 B.C.), who wrote that “time is the number of movement in respect to the before and after” (Physics IV), to more recent thinkers such as Bergson (1889/1967), who claimed that number is related to space but not to our experience of time. The relationship between time and number has been less widely investigated by developmental psychologists.

Dealing with time is an absolute necessity to organize life in society (for work, meals, leisure, etc.) (Fraisse, 1957), and this has led to the creation of conventional unit systems. Children need to develop some knowledge about these systems even if they are starting to have a primitive “sense of time” linked to actions—time to go to bed, duration of a pleasant/unpleasant event, and so forth. Both aspects, the conventional system of time units and the sense of time, have been assimilated to time knowledge (Friedman, 1990a). Time knowledge (TK), precisely defined here as the correct representation and use of the various time units (e.g., seconds, minutes, hours, days, weeks, months, seasons, years), has not been widely studied, nor has its development. Whereas using time units implies a proper representation and use of numbers (e.g., “It is 10 o'clock on the 25th day of the 9th month in the year 2015”), children's development of time knowledge is logically linked to the development of their numerical competencies.

However, up to now, most studies have been devoted to time perception over short durations without using verbal answers involving time units (for a review, see Droit-Volet, 2013). These studies reveal that the ability to judge time precisely in a wide variety of temporal tasks improves during childhood via the development of selective attention and working memory (Droit-Volet & Zelanti, 2013). As far as we know, the relationship between TK and numerical competencies has not been systematically examined in children, probably because of the lack of a tool for TK evaluation. Therefore, our aim was twofold: first, to study TK development during childhood and, second, to investigate the links between TK and children's numerical abilities. For the purposes of this study, we developed a Time Knowledge Questionnaire to evaluate the correct representation and use of the various time units.

### *Evaluation of TK: previous and new components*

Different aspects of TK, such as present-time awareness, using a calendar (Fraisse, 1957; Friedman, 1990a; Godart & Labelle, 1998), and telling the time on a clock (Burny, Valcke, & Desoete, 2009; Cohen, Ricci, Kibby, & Edmonds, 2000; Friedman & Laycock, 1989; Vakali, 1991), have already been investigated in children. Present-time awareness, also called time orientation, is the awareness of the present hour, day, month, year, or season. Awareness of the present day is thought to be acquired at the end of kindergarten at around 6 years, whereas that of the present month, season, or year occurs later in primary school at 7 or 8 years (Friedman, 1990a).

Other aspects of TK, more related to the experience of time, have been less widely envisaged. For example, the representation of time units might depend on implicit learning, such as experience-based knowledge (e.g., “A familiar activity takes  $x$  minutes/seconds/hours”), which could be clinically relevant. Indeed, children with autistic spectrum disorders have been shown to perform less well than typically developing children when durations were to be compared (e.g., eating a banana, going to a swimming pool) (Janeslätt, Granlund, Kottorp, & Almqvist, 2010).

Children's estimation of time during a long ongoing activity has rarely been studied (e.g., in the case of an interview duration, “For how long have we been here together?”), unlike children's percep-

98 tion of short intervals (a few seconds), where children are asked, for instance, to reproduce the time  
99 interval (e.g., Droit-Volet, 2013) without a verbal answer in the form of a number of time units.

100 In addition, children's representations of the life span have rarely been investigated. Life-span rep-  
101 resentations have been explored in studies of children's conceptual development in biology. For  
102 instance, the understanding of irreversibility of growth for humans, animals, and plants has been  
103 explored in typically developing children (Inagaki & Hatano, 1996; Labrell & Stefaniak, 2011;  
104 Maurice-Naville & Montangero, 1992; Rosengren, Gelman, Kalish, & McCormick, 1991) and in pedi-  
105 atric populations such as survivors from cerebellar tumors (Labrell, Kieffer, Grill, & Dellatolas,  
106 2014). However, investigations examining how children estimate the duration of growth and ageing  
107 (e.g., between infancy and childhood, between childhood and adulthood, between adulthood and  
108 old age) are lacking.

109 Lastly, few studies have investigated time intervals based on birthdays, for instance, how children  
110 progressively orient themselves with respect to their own birthdays. According to Godart and Labelle  
111 (1998), 33% of a sample of 9-year-olds made a correct estimation of the present–next birthday time  
112 interval versus 16% for the present–last birthday time interval.

113 As far as we know, none of the above dimensions (i.e., classic present-time awareness, telling the  
114 time on a clock, and explicit knowledge of time units), nor any of the less investigated dimensions  
115 (e.g., the estimation of (a) durations longer than a few seconds, (b) human life span intervals, and  
116 (c) birthday-based intervals), have ever been combined in the same tool. Consequently, correlations  
117 between all of these different aspects of TK during development are not well known, and it remains  
118 unclear how many different dimensions of TK (e.g., one or more than one) should be considered.

#### 119 *Time knowledge: relationships with numerical skills and underlying mechanisms*

120 TK acquisition enables everyday time judgments. For instance, TK enables children to locate them-  
121 selves in time, from the present moment to the more or less close past or future. The verbal sequences  
122 of days and months are learned during early primary school (Fraisse, 1957; Friedman, 1990a; Godart &  
123 Labelle, 1998). According to Friedman (1983, 1984, 1986, 1990b), children first develop a list-based  
124 representation of the days and the months, relying on lexical working memory, before being able to  
125 use an analogous spatial representation of the time intervals between days and months. Moreover,  
126 these time sequences rely on logical reasoning, particularly seriation performance (Friedman, 1977),  
127 and involve an understanding of the linear and cyclic nature of time given that days and months  
128 not only occur but also recur in a specific order.

129 Location in time implies a correct use of time units (e.g., seconds, minutes, hours, days, weeks,  
130 months, seasons, years), relying both on the mastery of the verbal sequences of the time units and  
131 on the numerical abilities of counting (using forward and backward sequences) and mental calcula-  
132 tion. Indeed, the sequences of time units are closely related to numbers, and especially to counting  
133 (e.g., days of the week, months, years, hours), but also to subtracting (e.g., “How long is it to my birth-  
134 day from now?”). The Chinese calendar in particular is based on an arithmetical labeling of each day or  
135 month (e.g., March is “month three”), but many other languages also use arithmetical labels for the  
136 days of the week (e.g., in Portuguese: second, third, fourth, fifth, and sixth for Monday–Friday; in mod-  
137 ern Greek: second, third, fourth, and fifth for Monday–Thursday).

138 Numbers are also involved in telling the time on a clock, which is a complex cognitive activity rely-  
139 ing on mathematics, (Andersson, 2008; Burny, Valcke, & Desoete, 2011; Cohen et al., 2000; Friedman &  
140 Laycock, 1989; Vakali, 1991) as well as on several domains of competence such as language (Bock,  
141 Irwin, Davidson, & Levelt, 2003), visuospatial skills (Eden, Wood, & Stein, 2003), and conceptual rep-  
142 resentations (Burny et al., 2009). In particular, explicit knowledge of the relationships between time  
143 units (e.g., how many hours in a day, how many minutes in an hour) has been considered as a prereq-  
144 uisite for correct use of analogue and digital clocks (Burny et al., 2009, 2011; Cohen et al., 2000;  
145 Friedman & Laycock, 1989). It has been shown that most children are able to read both analogue  
146 and digital clocks correctly at the age of 8 to 10 years (Burny et al., 2009).

147 Correct representation and use of time units is probably related not only to knowledge of numbers  
148 and computation but also to the so-called “cognitive estimation” of quantities (Harel, Cillessen, Fein,  
149 Bullard, & Aviv, 2007). This cognitive estimation has at least two components: the first relating to the

150 “theory of magnitude” and the second relating to contextual estimation. These two components are  
151 thought to rely on two different brain areas: the inferior parietal cortex and the frontal lobe,  
152 respectively.

153 First, it has been proposed that the estimation of the magnitude of a number and the estimation of  
154 a time interval rely on the same process (for a review, see Allman, Pelphrey, & Meck, 2012)—a mode  
155 control model generating an estimate of the magnitude of a duration or nonsymbolic numerosity from  
156 an accumulation of “pulses” compared with stored criteria of a given duration or number (Meck &  
157 Church, 1983; Meck, Church, & Gibbon, 1985). Walsh (2003) proposed a theory of magnitude postu-  
158 lating that the same cognitive system, located in the inferior parietal cortex, is devoted to common  
159 processing mechanisms for the evaluation of time, number, and space. Several studies on the nonsym-  
160 bolic “sense” of number and time showed a primitive time and number sense during infancy that is  
161 based on ratio (rather than absolute) differences in magnitude (Provasi, Rattat, & Droit-Volet, 2011).  
162 One and the same developmental progression for temporal discrimination and number discrimination  
163 during infancy has been suggested (Brannon, Suanda, & Libertus, 2007). The “triple code” model for  
164 numbers (i.e., verbal, Arabic, and analogical) also supposes an analogical representation associating  
165 a quantity with a number (Cohen & Dehaene, 1996; Dehaene, 1992).

166 Second, the correct representation of time units might also be related to another “cognitive estima-  
167 tion” of quantities linked to everyday and contextualized activities. This concerns, for instance, the  
168 estimation of the time needed to carry out an activity, as in the Biber Cognitive Estimation Test  
169 (Bullard et al., 2004), also studied during childhood (Harel et al., 2007). These estimations are thought  
170 to rely on mental control and planning, which are generally considered to be frontal lobe functions  
171 (Shallice & Evans, 1978), and not exclusively on “magnitude” given that the same quantity (e.g., 10)  
172 may be “a lot” (e.g., 10 children in the same family) or “a few” (e.g., 10 leaves on a big tree).

### 173 *Aims and hypotheses*

174 We investigated the development of most aspects of TK, from 6 to 11 years, and its link with chil-  
175 dren’s numerical competencies. We hypothesized that TK development is not linear because the dif-  
176 ferent numerical components are thought not to be acquired at the same age. Indeed, TK is likely to be  
177 linked to at least three aspects of numerical abilities: (a) the knowledge of numbers and number facts  
178 involved in devices that measure time such as clocks and calendars, (b) analogical estimation, and (c)  
179 contextual estimation. For example, we hypothesized that knowledge of numbers might be acquired  
180 earlier than contextual estimation, which is thought to rely on children’s experience of everyday and  
181 contextualized activities. It can be recalled that the (b) and (c) aspects above are thought to be pro-  
182 cessed in two different brain areas.

183 Consequently, the links between TK and numerical abilities might be different according to chil-  
184 dren’s age. Educated adults are expected to perform perfectly on TK when it concerns the usual time  
185 units (i.e., from seconds to years); however, most adults do not know that  $10^{-24}$  s is a yoctosecond and  
186 that  $10^{24}$  s is a yottasecond. As a consequence, correlations between usual TK and numeracy cannot be  
187 estimated in adults. In children, some subcomponents of number processing may be perfectly  
188 acquired by older children (e.g., counting, reading and writing Arabic numerals) but not by younger  
189 children. Conversely, other subcomponents of number processing (e.g., calculation) may show floor  
190 effects in younger children, making it difficult to estimate their correlation with TK, whereas this is  
191 not so among older children.

## 192 **Method**

### 193 *Participants*

194 The participants were 105 school children from Grade 1 to Grade 5, 57 girls (54%) and 48 boys  
195 (46%), aged 6.2 to 11.1 years. Each school grade corresponded to a different age range (see Table 1).  
196 Children were recruited in their schools, with informed consent to participate in the study obtained  
197 from both parents. Teachers asked children with no special educational needs or behavioral or neuro-

**Table 1**  
Participants' school grade, gender, and age.

School grade	Age group (years)	n	Girls [n (%)]	Age in years [mean (SD), range]
1	6	17	8 (47)	6.41 (0.14), 6.2–6.7
2	7	19	12 (63)	7.52 (0.13), 7.2–7.7
3	8	26	13 (50)	8.71 (0.26), 8.1–9.0
4	9	24	11 (46)	9.51 (0.29), 9.0–10.0
5	10	19	13 (68)	10.58 (0.29), 10.1–11.1
Total		105	57 (54)	8.65 (1.40), 6.2–11.1

198 logical difficulties to join the sample. The participants came from a representative sample of the  
199 French population living in a relatively large city (200,000 inhabitants) near Paris. They were recruited  
200 via state schools.

201 *Materials*

202 Two tools were used: our ad hoc Time Knowledge Questionnaire (TKQ) (see [Appendix A](#)) and the  
203 Zareki-R (Neuropsychologische Testbatterie für Zahlenverarbeitung und Rechnen bei Kindern-R)  
204 (Von Aster & Dellatolas, 2005; Von Aster, Deloche, Dellatolas, & Meier, 1997). The Zareki-R enables  
205 measures of numerical skills (counting dots, dictation of numbers, reading numbers, and oral and  
206 written comparison of pairs of numbers), analogical representation of numbers (number line estima-  
207 tion), and cognitive estimation (contextual estimation). Some subtests (e.g., comparison of numbers  
208 presented orally) strongly depend on verbal working memory (see [Appendix B](#)).

209 *Time Knowledge Questionnaire*

210 The TKQ ([Appendix A](#)) comprises seven subtests. The first four subtests investigated conventional  
211 time knowledge: orientation (OR), sequences (SEQ), time units (TU), and telling the time on a clock  
212 (CL), and comprised 5, 3, 4, and 5 questions, respectively. The questions about telling the time on a  
213 clock used pictures of five analogue clocks with five different positions of the minute and hour hands.  
214 Each answer was coded as correct (1 point) or incorrect (0 points), for a total conventional time score  
215 from 0 to 17.

216 The fifth subtest, life span (LS), used four pictures (a baby, a child, a young man, and an old man)  
217 illustrating the biological process of ageing (see [Fig. 1](#)). A fair-haired man, depicted at four different  
218 stages in development from infancy to old age, was chosen. The child was asked three questions about  
219 the time required to go from one age to the next (i.e., from baby to child, from child to young man, and  
220 from young man to old man). Each answer was coded as 0, 1, or 2 points. The coding rule was based on  
221 the answers of 20 adults that were as follows: from baby to child, median = 6 years, range = 4 to 10;  
222 from child to young man, median = 22 years, range = 15 to 30; from young man to old man, med-

**Fig. 1.** Material for the life-span questions.

ian = 35 years, range = 20 to 55. Two points were given if the child answered in the adult range. One point was given if the answer was borderline (i.e., not in the adult range but not clearly impossible), that is, within the following intervals: baby–child, 2 to 3.99 and 10.01 to 15 years; child–young man, 5 to 14.99 and 30.01 to 40 years; young man–old man, 55.01 to 90 years. No points were given for answers outside of these ranges or for “don’t know” answers (total LS score from 0 to 6).

The sixth subtest, birthday (BIR), comprised six questions. Questions 1 to 3 (“How old are you?”, “What age were you last year?”, and “How old will you be next year?”) were not taken into account in the calculation of the score because the answers were invariably “correct” (i.e., the absolute difference between the given age and the exact age was always less than 1 year). The other three questions regarding birthdays were “When is your birthday?”, “How long ago was your birthday?”, and “How long is it to your next birthday?” For these three questions, the correct answer was available (for each child, date of birth and date of interview were recorded), which made it possible to use a coding for error. Zero points were given if the child did not know the date of his or her birthday. Otherwise, for both of the last two questions (i.e., time intervals to the previous and next birthdays), 0 points were given for “don’t know” and answers exceeding 12 months, and 1, 2, and 3 points were given for errors (i.e., absolute difference between the answer and the correct interval) greater than 3 months, between 3 months and 1 month, and less than 1 month, respectively (i.e., total BIR score from 0 to 6).

The last subtest was interview duration (ID). At the end of the interview, the examiner asked the child, “For how long have we been here together?” The median duration of the interview was 15 min ( $Q3-Q1 = 14-21$  min, range = 5–42). Zero points were given for “don’t know” answers. For all other answers, 0 to 10 points were given according to the absolute difference between the log of the real duration of the interview and the log of the answer (in minutes) (see Appendix C for an illustration of this scoring method).

Two subtests from the TKQ, sequences and time units, were based on a previous study on time conceptions in children treated for malignant cerebellar tumors (Labrell et al., 2014) given that the cerebellum has been implicated in time perception. Other dimensions linked to time knowledge, such as children’s estimation of the duration of several daily activities (e.g., brushing their teeth, going from home to school), were investigated in this earlier study but were not retained in the current study for psychometric reasons (insufficient internal consistency). In the previous study, we were also interested in children’s understanding of time in the biological process of growth. Therefore, we used the same pictures from the life span subtest, but we did not ask for the time lapse between the different stages.

### Zareki-R

The Zareki-R (Appendix B) is a battery for the evaluation of number processing and mental calculation in school children. It contains 11 subtests evaluating knowledge of the verbal sequence of numbers and acquisition of the principles of counting (counting dots and counting backward), knowledge of the oral and written forms of numbers (reading numbers and writing numbers under dictation, comparison of numbers, all written presentations of numbers in Arabic numerals, and comparison of numbers presented orally), mental calculation (orally presented additions, subtractions, and multiplications), problem solving (presented orally), number line estimation (positioning integers  $>0$  and  $<100$  on a 0–100 line), perceptual estimation (giving the approximate number of elements seen without counting), and contextual estimation (deciding whether a given number in a given situation is “a few,” “a medium number,” or “a lot”).

### Procedure

The experimenter interviewed each child separately at his or her school in a quiet room, with the order of presentation of each tool being random. Sessions lasted approximately 50 min. For the TKQ, the experimenter asked the child to answer the interview questions from the pictures for telling the time on a clock and life span with no time limit. However, the experimenter recorded the time at the beginning of the TKQ, and also at the end, in order to compute the error for the final interview duration answer. The child’s answers were fully transcribed.

273 For the Zareki-R, the experimenter used the test as scheduled in the handbook, that is, with visual  
274 material when required (for counting dots, reading numbers, number line estimation, perceptual esti-  
275 mation, and written comparison).

276 **Results**

277 *TKQ subtests in relation to children's age: generation of a total TKQ score*

278 A total TKQ score (TKS) was computed, summing the scores on each subtest (max = 39 points; see  
279 Table 2) as well as three partial scores for conventional time (sum of the first four subtests), long dura-  
280 tions (sum of the birthday and life span subtests), and interview duration.

281 Performance increased with age for all of the subtests in the TKQ ( $p < .001$  in all cases). Table 2  
282 shows a comparison of the means of the subtests and the total TKQ scores across the five age groups.  
283 For the TKS, post hoc comparison of the means (Scheffé test) showed significant differences across all  
284 successive age groups except between the 8- and 9-year age groups. For the subcomponents of the  
285 TKQ, the improvement between the 6- and 7-year age groups was always significant except for life  
286 span (see Table 2 for more details of the post hoc comparison of the means).

287 Correlations across the seven subtests were all positive and significant at  $p < .001$  (Cronbach's  
288 alpha = .86). A principal components analysis confirmed the unidimensional structure of the TKQ (first  
289 factor explaining 54% of the variance, loading of the seven subtests on the first factor between .63 and  
290 .83, and eigenvalue of the second factor  $< 1$ ), justifying the computation of a total TKQ score. However,  
291 when age was partialled out, some partial correlations between the first four conventional time knowl-  
292 edge subtests and the last three subtests were close to 0 (e.g., between telling the time on a clock and  
293 birthday or life span). The age-adjusted alpha was .66 (see Table 3).

294 The correlation between total TKQ score and total Zareki-R score was high (.84) and remained high  
295 when age was partialled out (.60). All 11 subtests in the Zareki-R were positively correlated with the  
296 total TKQ score, with Pearson's  $r$  values ranging from .33 (perceptual estimation) to .77 (reading num-  
297 bers). These correlations remained significant when age was taken into account except for perceptual  
298 estimation and written comparison.

299 In summary, the greatest improvement in time knowledge was observed between the 6- and 7-  
300 year age groups and, to a lesser extent, between the 7- and 8-year age groups, with only a slight  
301 improvement after 8 years. However, the developmental pattern was different according to the sub-  
302 test. For instance, orientation (present-time awareness) exhibited a ceiling effect in children from 7  
303 years of age; in contrast, estimation of interview duration continued to improve between the 9-  
304 and 10-year age groups. The TKQ showed a unidimensional structure, justifying the computation of  
305 only one score summing the subscores; however, this was partly due to the correlation of all the sub-

**Table 2**  
Means (and standard deviations) of the subtests in the TKQ according to children's age.

Age group: (n):	Max	6-7 (17)	7 (19)	8 (26)	9 (24)	10 (19)	Total (105)	F (4,100)	p
Orientation (OR)	5	3.6 (1.2)	4.7 (0.6)	4.9 (0.3)	4.9 (0.4)	5.0 (0.0)	4.6 (0.8)	16.4	<.001
Sequences (SEQ)	3	0.9 (0.8)	2.1 (1.0)	2.4 (0.7)	2.5 (0.6)	2.9 (0.3)	2.2 (0.9)	18.3	<.001
Time units (TU)	4	1.7 (0.9)	3.1 (0.8)	3.7 (0.7)	3.8 (0.5)	3.9 (0.2)	3.3 (1.0)	35.9	<.001
Telling the time on a clock (CL)	5	2.1 (1.6)	3.7 (1.0)	3.7 (0.9)	4.3 (0.6)	4.9 (0.3)	3.8 (1.3)	21.6	<.001
Life span (LS)	6	2.1 (2.0)	3.7 (2.2)	4.8 (1.5)	4.6 (1.5)	5.2 (0.8)	4.2 (1.9)	10.2	<.001
Birthday (BIR)	6	1.6 (2.0)	3.8 (2.0)	4.7 (1.5)	5.2 (1.1)	5.5 (0.7)	4.3 (2.0)	19.7	<.001
Interview duration (ID)	10	4.0 (3.6)	5.7 (3.6)	8.2 (1.5)	7.10 (2.7)	8.90 (1.2)	6.94 (3.1)	10.4	<.001
Total score (TKS)	39	15.9 (6.0)	26.9 (7.0)	32.3 (4.1)	32.3 (3.1)	36.3 (2.1)	29.38 (8.1)	50.5	<.001

Note. Significant age effect at  $p < .0001$  for all six subscores. Post hoc comparison of the means (Scheffé test): OR, SEQ, TU, CL, BIR, ID, TKS: 6 < 7, 8, 9, 10; LS: 6 < 8, 9, 10; TU, ID, and TKS: 7 < 8, 9, 10; BIR: 7 < 10; CL: 7, 8 < 10; ID and TKS: 8, 9 < 10.

**Table 3**

Correlations and age-adjusted partial correlations between the “time” subtests.

	SEQ	TU	CL	LS	BIR	ID
OR	.50 (.29)	.52 (.28)	.49 (.26)	.38 (.19)	.47 (.23)	.32 (.10)
SEQ		.59 (.32)	.52 (.25)	.38 (.13)	.64 (.43)	.43 (.21)
TU			.56 (.23)	.51 (.27)	.59 (.29)	.45 (.19)
CL				.29 (.02)	.38 (.003)	.36 (.09)
LS					.57 (.39)	.33 (.14)
BIR						.44 (.21)

Note.  $p < .05$  if  $r > .20$ ;  $p < .01$  if  $r > .25$ ;  $p < .001$  if  $r > .32$ ;  $\alpha = .86$ ; age-adjusted  $\alpha = .66$ . OR, orientation; SEQ, sequence; TU, time units; CL, telling the time on a clock; LS, life span; BIR, birthday; ID, interview duration.

306 tests with age. Within each age group, it remains questionable whether the TKQ can be considered as  
307 unidimensional.

308 *Overall observed correlations between the TKQ score and the Zareki-R score*

309 A linear regression with TKQ score as the dependent variable and the 11 Zareki-R subtests as  
310 explanatory variables showed that four subtests remained significant at  $p < .05$ : reading numbers,  
311 number line estimation, oral comparison, and contextual estimation. A backward selection confirmed  
312 that these four subtests explained 75% of the variance of the total TKQ score, which was almost the  
313 same as the percentage of variance explained by the 11 subtests (77%) (see Table 4).

314 The same regressions with backward selection ( $p < .01$  for a variable to be retained) were per-  
315 formed with dependent variables in the form of three partial scores on the TKQ: a “conventional time  
316 score” (CTS, the sum of the four first subtests in the TKQ), a “long durations” score (LDS, the sum of the  
317 birthday and life span subtests), and the interview duration score (IDS). The subtests in the Zareki-R  
318 selected were only one subtest for IDS (number line estimation), two subtests for LDS (reading num-  
319 bers and contextual estimation), and three subtests for CTS (mental calculation, reading numbers, and  
320 contextual estimation).

321 In sum, these results show a strong association between time knowledge and number processing in  
322 typically developing children. Furthermore, the results also suggest that different cognitive processes  
323 involved in time processing influence TK (number knowledge, perception of magnitude, contextual  
324 estimation, and verbal working memory involved in number comparisons).

**Table 4**

Relationships of the total time score with the subtests and the total score of the Zareki-R number processing and calculation battery.

<sup>a</sup> Age-adjusted partial correlation.

325 *Correlations between the Zareki subscores and the total TKQ score according to children's age*

326 Correlations between subtests in the Zareki-R and total TKQ score varied according to age (Table 5).  
 327 No clear pattern appeared in the younger children (6 years), who showed floor effects in many sub-  
 328 tests. In the older children (10 years), contextual estimation was the only subtest showing a strong  
 329 positive link with TKS. Reading numbers was linked with TKS at 7 years, oral comparison at 7 and  
 330 8 years, and positioning a number on a scale at 7 and 9 years. In summary, these results suggest that  
 331 associations of TK with specific number processing subtests change with age.

332 **Discussion**

333 The current study in typically developing school children aged 6 to 11 years describes the develop-  
 334 ment of TK and analyzes the relationships between overall TK development and numerical skills. The  
 335 proposed definition of TK (i.e., the correct representation and use of the various time units) implies  
 336 numbers. We hypothesized that TK is linked to at least three aspects of numerical abilities: the knowl-  
 337 edge of numbers, analogical estimations, and contextual estimations.

338 *Development of time knowledge*

339 The TKQ used for the evaluation of TK included subtests widely investigated in previous studies in  
 340 typically developing children (for orientation or present-time awareness, see Friedman, 1983, 1984,  
 341 1990b; for temporal sequences, see Friedman, 1977, 1986, 1990b; for telling the time on a clock,  
 342 see Burny et al., 2009; Cohen et al., 2000; Friedman & Laycock, 1989; Vakali, 1991) and also new sub-  
 343 tests such as those exploring children's representation of long durations (life span and birthday).  
 344 Despite this seemingly heterogeneous composition, the TKQ showed a relatively unidimensional  
 345 structure, justifying the generation of a total score. However, this one-factor solution was partially  
 346 attributable to age differences, as suggested by the lower age-adjusted partial correlations between  
 347 the subtests and especially the partial correlations close to 0 between some conventional TK subtests  
 348 (telling the time on a clock) and the subtests concerning long durations (birthday and life span). This  
 349 observation led to the generation of three partial scores in addition to the total TKQ score: a conven-  
 350 tional time score (sum of the first four subtests), a long duration score (sum of birthday and life span),  
 351 and the interview duration score.

352 A strong age effect on all subtests in the TKQ was observed as well as many developmental patterns  
 353 already reported in previous studies. For example, Friedman (1977, 1990b) provided evidence that

children master time orientation at around 7 years of age. Indeed, knowledge of numbers on which time orientation depends is largely school dependent.

In contrast, the children's precise representation of life-span intervals (LS subtest) scored lower than in adults even at 10 years of age. Accurate estimation of the three time intervals (baby–child, child–young man, and young man–old man) appeared to be a very difficult task for young children. It can be considered that, in order to succeed in the LS subtest, respondents need to attribute an age to each stage and also to perform a subtraction (e.g., age of the adult minus age of the child) in the same manner as adults do. The age for mastering subtraction in French children is approximately 8 years (Von Aster & Dellatolas, 2005). Correct estimations of the probable age of each human figure (the baby, the child, the young man, and the old man) have not been studied in children's biological conceptions and might depend on their experience of the real world.

The results about birthdays showed that the children were capable of accurately identifying their birthdays only during the primary school years. This progression in children's ability to position their birthdays in time, based on past and future events, corroborates Friedman's (2000) findings regarding children's knowledge of the time to future events as occurring between 7 and 10 years.

### *Relationships between time knowledge and numerical skills*

The total TKQ score was strongly related to numerical skills, explaining 70.6% of the variance ( $r = .84$ ) when only the total Zareki-R score was considered and 77% of the variance when performances on the 11 numerical subtests were considered. Regression analyses showed that four numerical subtests explained an almost equivalent proportion of the variance (75%): reading numbers, number line estimation, contextual estimation, and comparison of numbers presented orally.

When the three partial TKQ total scores (rather than the total TKQ score) were the dependent variables, the same subtests in the Zareki-R were selected. Number line estimation was the only subtest retained for IDS; mental calculation, reading numbers, and contextual estimation were retained for CTS; and reading numbers and contextual estimation were retained for LDS. In other words, as hypothesized, TK was found to be predicted by different numerical skills.

Each of these numerical predictors of TK represents a different domain of numerical skills. For the conventional time score, reading numbers and mental calculation are clearly school dependent, as is knowledge of the relationships between time units (e.g., "One hour is 60 minutes"). To master time sequences or units, and to tell the time on a clock correctly, children need to compute with numbers.

The regression analysis predicted the interview duration score only from number line estimation, which requires a quantity to be associated with a number (Dehaene, 1992). Indeed, to solve this task, children need to master the analogical representation of the "triple code" model (Cohen & Dehaene, 1996). In other words, children encountering difficulties in evaluating the passage of time need to be trained in the analogy between quantity and number.

The predictors of long duration score were reading numbers (necessary to identify ages of life span and birthday) and contextual estimation. This numerical ability involves an accurate judgment about quantities, whereby a large number may be "a few" (e.g., 200 fans at a football game) and a small number may be "a lot" (e.g., 10 children in a family). The ability to make such judgments requires general knowledge of the world. This knowledge is needed to answer some items in the TKQ correctly. For example, when children are asked to evaluate the duration of developmental periods (from infancy to childhood, from childhood to adulthood, and from adulthood to old age), they need to know how time is involved in human growth and also that the change in appearance is not proportional to the time intervals. According to Shallice and Evans (1978), contextual estimation is based on executive functions. These functions are also involved in conventional time knowledge (e.g., to answer questions such as "Can you tell me the seasons of the year in order?" and "Is a month shorter or longer than a year?"), and they are also needed to estimate the time required to plan daily activities (Harel et al., 2007).

Lastly, the results about the relationships between TK development and numerical skills according to children's age have shown that, as predicted, the significant numerical subtests were not the same according to children's age. First, reading numbers, number line estimation, and especially oral comparison were the subtests that were most correlated with the total TKQ score for the youngest children

(i.e., 7 and 8 years). Indeed, working memory, which is involved in oral comparison, is the executive function young children need to answer all of the subcomponents in the TKQ (i.e., present-time awareness, telling the time on a clock, birthday, life span, and duration of the interview). Second, number line estimation was the most strongly correlated subtest with the total TKQ score among children from 9 years. For these children, time knowledge appeared to be mostly linked to the ability to associate a quantity with a number, as for the birthday, life span, and duration of the interview subtests. Third, contextual estimation, thought to rely on children's general knowledge of the world, was the most strongly correlated subtest with the total TKQ score in 10-year-old children, the oldest group.

#### 414 *Limitations and perspectives*

415 Due to ceiling effects for some subtests in the TKQ (e.g., orientation) and to floor effects for others  
416 (e.g., life span), interpretation of the results of the correlation analyses according to children's age  
417 should be made with caution. Further studies are needed with more participants by age group in order  
418 to (a) propose new versions of the TKQ better adapted to each age group and (b) examine whether the  
419 structure of the TKQ is unidimensional or not within each age group.

420 Future studies should investigate the role of cognitive factors, especially verbal skills, in the rela-  
421 tionship between time knowledge and numerical skills. The above-mentioned four components of  
422 the Zareki-R involved in time knowledge may be differentially impaired in children with developmen-  
423 tal disorders such as children with developmental dyslexia, specific language impairment (Gooch,  
424 Snowling, & Hulme, 2011; Helland & Asbjornsen, 2003), or specific nonverbal deficits. Studies in these  
425 special populations of children could clarify the roles of language, reading, and/or visuospatial skills in  
426 TK acquisition.

#### 427 **Appendix A. The Time Knowledge Questionnaire**

428 *Orientation (OR)*: (1) What day is it today? (2) What time is it\*\*? (3) In what month are we? (4) In  
429 what year are we? (5) In what season are we?

430 *Sequences (SEQ)*: (1) What month comes after March? (2) Can you tell me the months in the year in  
431 order? (3) Can you tell me the seasons in the year in order?

432 *Time units (TU)*: (1) Is a minute shorter or longer than a second? (2) Is a week longer or shorter than  
433 a month? (3) Is a month shorter or longer than a year? (4) How many hours are there in one day, from  
434 one day in the morning to the next day in the morning?

435 *Telling the time on a clock (CL)* (six images of a clock): (1) Show me 2 o'clock. (2) Show me 10 to 3.  
436 (3) Show me a quarter past 8. (4) Show me 10 past 11. (5) Look at this clock. How many minutes is it to  
437 2 o'clock?

438 *Life span (LS)* (four pictures: baby, child, young man, and old man): How long does it take: (1) for a  
439 baby (here) to become a child (here)? (2) for a child (here) to become a young man (here)? (3) for a  
440 young man to become an old man?

441 *Birthday (BIR)*: (1)\* How old are you? (2)\* When is your birthday? (3) How long ago was your birth-  
442 day? (4) How long is it to your next birthday?

443 *Interview duration (ID)*: (1) For how long have we been here together?

444 \*Questions not considered in the calculation of subscores and total score.

445 \*\*Considered as correct if the child's answer is in the same half day (if it is 10 o'clock and the  
446 answer is "it is 8 o'clock" or "it is midday," the child's answer is considered as correct, but if the child's  
447 answer is "it is 4 p.m.," it is considered as incorrect).

#### 448 **Appendix B. The 11 subtests of the Zareki-R**

449 *Counting dots (CoDo)*: Presented on six cards with 13, 5, 15, 10, 8, and 18 dots, respectively. Score  
450 from 0 to 6.

451 *Counting backward (CoBa)*: From 23 to 1 and from 67 to 54. Score from 0 to 4.

452 Dictation of number (DicNu): Oral presentation of eight numbers to be written in Arabic numerals:  
453 14, 38, 1200, 503, 169, 4658, 756, and 689. Score from 0 to 16.

454 Mental calculation (Calc): Oral presentation of eight additions (5 + 8, 12 + 6, 4 + 13, 9 + 7, 15 + 12,  
455 13 + 19, 14 + 8, and 17 + 25), eight subtractions (17 – 5, 14 – 6, 24 – 17, 19 – 6, 15 – 9, 25 – 12,  
456 32 – 17, and 18 – 11), and six multiplications (3 × 2, 4 × 5, 3 × 4, 2 × 6, 5 × 3, and 4 × 4). Score from  
457 0 to 44.

458 Reading numbers (Read): Reading eight numbers written in Arabic numerals: 15, 57, 1900, 305, 138,  
459 6485, 687, and 969. Score from 0 to 16.

460 Number line estimation (NumLi): On vertical lines presented with a 0 at the bottom and a 100 at the  
461 top, the child is asked to mark the positions of 12 numbers: 86, 48, 5, 32, 93, 62, 53, 27, 76, 17, 59, and  
462 83. Score from 0 to 24.

463 Oral comparison (OrComp): The child must say which one of the two numbers presented orally in  
464 eight pairs is the larger of the pair: 51/49, 465/546, 2009/2090, 108/800, 612/389, 800/108,  
465 34601/9678, 46/64, and 1086/322. Score from 0 to 16.

466 Contextual estimation (ContEs): The child must evaluate whether 10 situations such as “four teach-  
467 ers in the same classroom,” “two clouds in the sky,” “three children in the same family,” “10 leaves on  
468 a tree,” and “eight lamps in the same room” are “a small number,” “a medium number,” or “a lot.”  
469 Score from 0 to 10.

470 Perceptual estimation (PercEs): The child must give an approximation of the number of dots seen  
471 (on two cards presented for 2 s each), the number of balls (on one card presented for 5 s), and the  
472 number of glasses (on one card presented for 5 s). The presentation time does not enable complete  
473 counting. Score from 0 to 5.

474 Problem solving (Prob): The child must solve six numerical problems of increasing difficulty pre-  
475 sented orally. For example, the first problem is, “Peter has 12 marbles. He gives 5 to his friend Ann.  
476 How many marbles does Peter have now?” Score from 0 to 12.

477 Written comparison (WritComp): The child must say which of two numbers presented in 10 written  
478 pairs is the larger of the pair: 13/31, 79/81, 1007/1070, 511/298, 654/546, 9768/35201, 96/69,  
479 201/102, 347/947, and 1238/11238. Score from 0 to 10.

#### 480 Appendix C. Scoring of the error between real interview duration (ID) and child's answer

481

Case	Real ID (a) (min)	Answer (b) (min)	Error: $ \log(a) - \log(b) $	Range of the error	Score
