Key words Stars: binaries: close – binaries: visual — astrometry – photometry — techniques: speckle interferometry, Lucky imaging, direct vector auto-correlation — instruments: 76-cm refractor

We present relative astrometric and photometric measurements of visual binaries made in 2009-2010, with the 76-cm refractor of Côte d’Azur Observatory and a pair of sensitive EMCCD ANDOR cameras. Our observing list consists of optical pairs and binaries whose orbital motion is still uncertain. Three different techniques were used for obtaining measurements: Lucky Imaging, Speckle Interferometry and the Direct Vector Autocorrelation method. From the 2050 observations of double stars that we performed, we obtained 1652 new measurements of the relative position of 1792 objects, with angular separations in the range $0''.1$ — $14''.1$. The average accuracy is estimated at $0''.02$ for the angular separations and $0''.6$ for the position angles. We managed to observe faint systems ($m_V \approx 12$) with large magnitude difference (up to $\Delta m_V \approx 5$). We have thus been able to measure many systems containing red dwarf stars that had been poorly monitored since their discovery. We also measured the difference of magnitude of the two components of 1143 objects with an estimated error of 0.2 mag.

[†]Deceased in October 2018

1 Introduction

This paper presents the observations of binary stars made in 2009-2010 with the 76-cm refractor telescope “Grande Lunette” of “Observatoire de la Côte d’Azur”, OCA observatory (i.e., French Riviera Observatory). This work is the continuation of the program described in Gili & Prieur (2012), that will be referred hereafter as Paper I. This program aims at obtaining high angular resolution measurements of binary stars with sensitive detectors, by using the good image quality of the site and the optics of the large Nice refractor, that often provides diffraction-limited images.

The observations presented here were first done with the ANDOR iXon DV885 EMCCD detector (see AN-

DOR, 2020), that was acquired by René Gili (1951-2018) in July 2008 (see Paper I) and later in 2009, with an ANDOR iXon DV897 EMCCD (SPICA) that was kindly lent to our team by Farrokh Vakili, the former Director of OCA. The DV897 detector is a thin back illuminated CCD chip with a higher quantum efficiency than that of the DV885 thick front-illuminated CCD chip (see Fig. 1). Furthermore, the DV897 camera has a higher reading frequency, and a more elaborated cooling system than the DV885 camera (see Table 1). As a result, our observations substantially gained in sensitivity and productivity through the year 2009.

Concerning the data reduction of the observations, the Lucky imaging method (basically a shift-and-add method applied to a selection of the best images) that was mainly used in 2007 (Gili & Agati, 2009) and in 2008 (Paper I) was progressively replaced in 2009 by other methods based on speckle interferometry, which

* Corresponding author: jean-louis.prieur@irap.omp.eu

Fig. 1 Quantum efficiency of the Andor DV885 EMCCD chip on the left and of the DV897 on the right (from www.andor.com).

lead to higher accuracy measurements and are less sensitive to atmospheric turbulence.

In this paper, we describe our observations and our instrumentation setup in Sect. 2. The procedure we followed for determining the scale and position angle calibration is detailed in Sect. 3 and the data reduction procedure is described in Sect. 4. Then we present and discuss our relative astrometric and photometric measurements in Sect. 5.

2 Instrumentation and observations

2.1 Observing list

Our list of targets basically includes all the visual binaries of the “Washington Double Star Catalogue” (Mason et al., 2020, hereafter: WDS) for which new measurements are needed to improve their orbits and that are accessible with our instrumentation. Among those, we particularly favoured the objects discovered by Paul Couteau (see Couteau, 1999 and Le Contel et al., 2001), as they have been neglected by other observers due to faint magnitudes and small separations. Indeed they are particularly well suited to the 76-cm refractor and its site, since most of them were discovered in Nice.

The distribution of the apparent magnitudes m_V of the primary components of the binaries observed in 2009-2010 is presented in Fig. 2a and the difference of magnitudes Δm_V between the two components in Fig. 2b. These data were retrieved from the WDS catalog. The telescope aperture and detector sensitivity led to a limiting magnitude of $m_V \approx 14$ for the faintest companions, which corresponded to about $m_V \approx 12$ for the binary systems (see Fig. 2a).

2.2 Description of the ANDOR DV885 and DV897 cameras

The observations presented here were carried with two EMCCD (Electron Multiplying CCD) detectors of ANDOR Technology: an iXon DV885 and an iXon DV897. From 2008, the DV885 detector was used at the focus of the great refractor, with the instrumental setup presented in Paper I and in Gili et al. (2014). An additional

Fig. 2 Distribution of the WDS visual magnitudes of the binary systems observed in 2009-2010 (a) and distribution of the WDS magnitude differences Δm_V between the two components (b).

LUCA detector was mounted at the direct focus of the finder scope of the great refractor, with a resulting field of view of $12''.3 \times 9''.3$, and two webcams were installed in front of the graduated right-ascension and declination circles. This allowed a single person to operate the telescope, and the pointing of stars as faint as $m_V \approx 14$ could be interactively controlled from the screen of a computer transformed into a dashboard. This permitted us to observe typically twenty binaries per hour. During autumn 2009, the DV885 was replaced by the DV897 detector, that was kindly lent to us by F. Vakili.

The main characteristics of the EMCCD detectors that we used for our observations in 2009-2010 are given in Table 1. The peak quantum efficiency values in Col. 6 are those given by the manufacturer of the chip for wavelengths in the range 550–720 nm, but they are unfortunately much smaller for the whole system. The mention “interleaved” (Col. 8) means that the pixel electronic charges were transferred from the sensitive matrix of the CCD to a masked interleaved matrix available on the same CCD chip. The mention “non-interleaved” is reported in Col. 8 in the absence of a masked CCD. A USB (Universal Serial Bus) cable was used with the LUCA to communicate with the camera and transfer the images from it to the computer (Col. 9), whereas a dedicated Andor board running the ‘Camera Link’ serial protocol was installed on the Peripheral Component Interconnect Bus (PCI bus) of the computer for the other cameras.

For the LUCA detector, the read-out noise is about 25 electrons in conventional mode and less than one electron in electron-multiplying (EM) mode. It works in interleaved mode and the images are transferred to the computer through a USB link.

For the iXon DV885 and the iXon DV897, the image transfer is made with a dedicated link between the detector and a CCI-22 controller board installed on a PCI slot of the computer. Such a dedicated board allows a high reading frequency and an acquisition rate of 27 and 35 full-size images per second, for the DV885

Table 1 Main characteristics of the ANDOR EMCCD cameras used for our observations: full format in pixels (Col. 2), pixel size in μm (Col. 3), digitization depth in bits/pixel of the encoded output values (Col. 4), read-out frequency rate (Col. 5), Peak Quantum Efficiency (P.Q.E.) of the detector (Col. 6), cooling temperature used during our observations (Col. 7), frame transfer mode, i.e. pattern method used for reading the data (Col. 8) and hardware used for the data link (Col. 9).

Name	Format (pixels)	Pixel size (μm)	Digit. (bits/pixel)	Read freq. (MHz)	P.Q.E. (%)	Cool. temp. ($^{\circ}\text{C}$)	Frame transfer	Data link
LUCA	658×496	10×10	14	12.5	50	-20	Interleaved	USB
DV885	1004×1002	8×8	14	27	65	-70	Non-interleaved	PCI board
DV897	512×512	16×16	16	10	92	-80	Non-interleaved	PCI board

and DV897, respectively. In fact, to reduce the noise in the images, we used a lower value of about 5 MHz for this reading frequency. Like the LUCA, the DV885 and DV897 detectors were used in EM mode, which reduced the read-out-noise of the output register to less than one electron in both cases.

Compared to the LUCA, the main advantage of the DV885 and DV897 for our observations was a lower noise level due to better cooling performances. Indeed those cameras were endowed with a three-stage Peltier device that allowed to cooling the detector down to -70° for the DV885 and even -80° for the DV897, without external heat-exchanger, whereas the LUCA detector could be cooled down to -20° only.

Most of the observations presented here have been obtained and reduced with the method presented in Paper I which used the ANDOR SOLIS data acquisition software. The images were recorded as three-dimensional cubes in the proprietary SIF-format in 32 bits and converted to 16-bit FITS individual files using SOLIS too. Final processing of those images in the frequential or spatial domain was done with the REDUC program (Losse, 2020).

Another acquisition program was progressively implemented during that period, with the development of a dedicated real time processing program **BuildSpeck1** by Jean-Louis Prieur. This program was derived from the **vcrb** program used in Merate (Brera Observatory, Italy) for the real time processing of the video analog signal produced by an ICCD camera (see Prieur et al., 2001). It also allowed a full control of all the available options of the ANDOR cameras and could be used for the LUCA, DV885 and DV897 cameras. This program was written in C++ language with the Borland C++ (version 5.02) library. This program was widely used for data acquisition after mid-2009 but was only marginally used for data processing until the end of 2010.

2.3 Optical setup and observing procedure

The observations reported here were thus made with the “Grande Lunette” of OCA Observatory. It is a 19th century 76-cm refractor, with a free aperture diameter of $D = 74$ cm. The limit of diffraction $\rho_D = \lambda/D$ is

$0''.16$ with $\lambda = 570$ nm, which corresponds to the average central wavelength of the filters we used. The “Journal of the observations” is presented in Table 2.

For most of our observations, we used the optical setup presented in Paper I, and magnified the images with a negative achromatic double lens (“Barlow”) of -113 mm focal length. Switching from one camera to another was easy and did not change the field size since the mechanical structure of the cameras was the same and since the sensitive areas of the DV885 and DV897 cameras had the same size. Indeed the product of the number of the pixels by the pixel size was almost the same for both (see Table 1). We changed this setup in November 2010 when we installed PISCO2 on the refractor. This instrument is described detail in Gili et al (2014).

Exposure times of elementary frames were set in the range 20–30 msec for all objects, independently of their magnitudes. The standard format of the acquisition window was 128×128 pixels which corresponded to a field of view of $8'' \times 8''$. For faint objects or wide pairs, a wider field of 256×256 pixels on the detector was used with a binning factor of 2×2 which thus amounted to 128×128 pixels for the elementary frames. To avoid saturation with bright objects, the EM gain was reduced and sometimes even put to “off”, which corresponded to observing in conventional CCD mode.

For each object, we recorded SIF cubes of 1000 elementary images. In average $1''.2$ seeing conditions, the typical limiting V magnitude was close to 14–15 with a binning mode of 1×1 .

As described in Paper I, the AF filter (anti-fringe or V-block) was mounted on the front window of the DV885 or DV897 detectors. This filter is bandpass 450–650 nm which considerably reduces the secondary spectrum of the 76-cm refractor, with no significant loss of energy in the V band. When combined with the transmission of the lenses and the quantum efficiency response of the detector, the resulting transmission curve is close to a standard V filter with a maximum transmission at around 570 nm.

Fig. 3 Calibration grating mask on top of the 76-cm refractor

3 Scale and position angle calibration

The astrometric calibration was first done using wide well-known couples with a separation of about $5''$, and then, after 2010, with a calibration grating mask (see Fig. 3). This mask was initially designed for the 50 cm refractor of the OCA Observatory, but could also be used on the 76 cm refractor. Its free entrance diameter is 50.5 cm with 23 occulting bands that are uniformly distributed with an average step of $a = 22.43 \pm 0.10$ mm. This grating mask simulates the observation of a double star whose separation is (see Scardia et al. 2007):

$$\theta = \lambda/a$$

where λ is the wavelength of the incident light, and θ is in radians. To obtain θ in arcseconds, we should multiply it by $3600 \times 180/\pi = 206265$. Hence

$$\theta_{\text{arcsec}} = 206265 \times \lambda/a$$

For $\lambda = 570$ nm, we obtain $\theta = 5''.2409 \pm 0''.0241$ for our grating mask.

Without the Barlow lens, the focal length was found to be 17.89 ± 0.005 m at the primary focus. With Barlow, the equivalent focal length was 26.93 ± 0.2 m and the scale was $0.0613''/\text{pixel}$ for the DV885 and DV897 cameras. The sampling of both detectors in the Barlow configuration is thus less than $\rho_D/2$ for $\lambda = 570$ nm. It then satisfies the Nyquist-Shannon theorem and allows measurements down to the telescope diffraction limit.

The calibration of the origin of the position angles was done recording star trails caused by the diurnal motion. We used the largest available field for this purpose, which was $53'' \times 40''$ with the DV897.

4 Data reduction procedure

A basic pre-processing of the elementary frames consisted in subtracting the mean offset corresponding to the same detector setup. For this purpose, series of 1000 offset frames (i.e. short-exposure dark frames) were recorded each night to SIF cubes until mid-2009 or later to FITS cubes.

The pioneering work of Labeyrie (1970) showed that high resolution information could be extracted from short-exposures by computing the average power spectrum of those exposures. This technique is known as

“speckle interferometry”, and has become the “standard” way of processing our data since 2008. Our processing method is described in Paper I. Conventional speckle interferometry, is based on the computation of the mean autocorrelation function of short exposures. This function is symmetric relative to the origin and does not contain any information about the location of the companion of the binaries (see Fig.4). As a consequence, the speckle measurements of the position angles of binaries have an ambiguity of 180° . To solve this problem, we also computed the direct vector autocorrelation (DVA), as proposed by Bagnuolo et al (1992), that is the “oriented” autocorrelation function and takes into account the brightness level of the vector ends. The DVA allows the quadrant determination and the measurement of Δm_F when the contrast is not too large (e.g. $\Delta m_F < 2$). As explained in Paper I, those determinations were done with the REDUC software (Losse, 2020), which was kindly specially adapted to our application by Florent Losse.

In the case of good seeing conditions, we obtained high resolution images with the Lucky Imaging method that was described in Paper I, and consisted in shift-and-add processing a subset of selected good images (see Fig.4). We experimentally found that a selection of about 3–10% of the best images of our 1000-frame cubes often led to very nice shift-and-add images, with clear Airy rings and a final resolution close to the diffraction limit of the 76-cm refractor. When the “Lucky images” were very noisy, we filtered them with wavelets or with an “over-sampling Spline-method” by a factor of three using the IRIS software (Buil, 2020). The final images were then processed with the REDUC software (Losse, 2020) that provided the θ , ρ and Δm_F measurements. We could measure couples with very large differences of brightness, up to 4–5 magnitudes (see Sect. 5). Compared to the speckle interferometry, the main advantage of “Lucky imaging” is to provide a full image which is convenient for the determination of the quadrants (where lie the companions) and of the difference of magnitudes between the two components.

5 Relative astrometric and photometric measurements

The relative astrometric and photometric measurements that we obtained in 2009–2010 are displayed in Table 5 (beginning only). The full version (Table 6) is available in the on-line version of the paper).

The position angle θ of the companion in degrees (Col. 8) was measured from the North and positive to the East. In Col. 12, we reported the O-C residuals of our θ and ρ measurements with a computed orbit if any was available (see Sect. 5.1). When the stars were not resolved by our observations and when an orbit was known, we indicate the ephemerides in square

brackets. In that column, we also added in parentheses some complementary comments that could not fit in Col. 11.

In Col. 11, the note ‘i’, ‘dva’, or ‘ly’ was added when the ρ , θ measurements were obtained with speckle interferometry, the DVA method (Direct vector Autocorrelation) or with the Lucky imaging method respectively (see Sect. 4 and Paper I). The letter ‘b’ indicates that the measurements were obtained in the binning mode with bins of 2×2 pixels (see Sect. 2.2). The location of the companion in a given quadrant relative to the North-East orientation could be done with the Lucky imaging or the DVA methods. The quadrants are noted 1Q, 2Q, 3Q and 4Q for the first (North-East), second (South-East), third (South-West) and fourth (North-West) quadrant, respectively. They are indicated in Col. 11 or Col. 12.

In those columns, we also give some other information:

- ‘S’ for Single star (i.e., not seen as double),
- ‘NR’ for Non-Resolved, although seen as double, and in some cases an estimate of the upper limit for the separation in arcseconds (e.g. < 0.16 for 00122+4647).
- ‘ND’ for New Double.
- A colon ‘:’ following one measurement indicates that measurement has a large uncertainty.
- An exclamation mark ‘!’ was added to some comments to underline those comments (i.e., the observations clearly showed them).

The difference of magnitudes Δm_F of the two components was obtained either from the Lucky Imaging or the DVA method. This is indicated with ‘ly’ or ‘DVA’ in Col. 11, and concerns 1143 objects (see Fig. 5b). The average errors are estimated at 0.2 mag. In Fig. 5c we have plotted our measurements Δm_F versus the WDS values (Δm_V). There is a fair correlation between the two. The big scatter shows that the relative photometry of many systems is still poorly known in the literature and that photometric observations are really needed.

The distribution of the 1652 angular separations measured in this paper is displayed in Fig. 5a and shows a maximum for $\rho \approx 0''.65$. The largest separation of $\rho = 14''.056$ was obtained for GII30 AB,C. The smallest separation was measured for A1798 with $\rho = 0''.103$. This is below the diffraction limit of $\rho_D = \lambda/D$ is $0''.16$ with our V filter (i.e. $\lambda = 570$ nm) and the refractor whose free aperture is $D = 0.74$ m. Some other objects could be measured under this limit. The closest separations, less than $0''.16$, that we obtained in 2009–2010 are listed in Table 3. This table shows that the residuals in angular separation are compatible with our measurements. The position angles have a larger orbit residual, which was expected since those measurements were obtained at the limit of our instrumentation. We could also check that our measurements

Fig. 4 Examples of "Lucky imaging" (LI) and "autocorrelation" (AC) images with the (θ, ρ) measurements that we obtained in 2009-2010. (a) LI of COU 14 in 2009., (b) AC of COU 14 in 2010, (c) AC of COU 542 in 2010, (d) LI of KUI 50 in 2009, (e) LI of SKF 245 AC in 2010 (f) wavelets filtered LI of SKF 245 AC in 2009. The position angle and angular separation were measured as $(33.3^\circ, 0.''30)$ for COU 14 in 2009.60, $(38.4^\circ, 0.''32)$ for COU 14 in 2010.64, $(63.2^\circ, 0.''19)$ for COU 542 in 2010.64, and $(20.7^\circ, 3.''26)$ for SKF 245 AC, whereas KUI 50 was not resolved. North is to the bottom and East to the right.

are in good agreement with other observations reported in the "Fourth Catalogue of Interferometric Measurements of Binary Stars" (Hartkopf et al., 2020, hereafter IC4).

From our 2050 observations of double stars, we were able to derive 1652 position measurements. There were 223 cases of unresolved objects that clearly appeared as single (S in Col. 11) or that appeared as an elongated spot although it was not possible to resolve this spot (NR in Col. 11). Some observations could not be used due to technical problems.

The average errors are estimated at $0''.02$ and $0^\circ.6$ for ρ and θ respectively (those values were determined from multiple measurements of the same objects). When the measurements had a large uncertainty, we added ':' after the corresponding values.

5.1 Comparison with published ephemerides

The $(O - C)$ (Observed minus Computed) residuals of the measurements for the systems with a known orbit in Table 5 are displayed in Cols. 11 and 12 for the po-

sition angle θ , and separation ρ , respectively. A Q was added to θ residuals when the quadrants of the measurements were not in agreement with those used for the orbits. The orbital elements used for computing the ephemerides were retrieved from the "Sixth Catalogue of Orbits of Visual Binary Stars" (Hartkopf & Mason, 2020, hereafter OC6). The corresponding authors are given in Col. 13, using the style of the OC6 references.

The 252 residuals from Table 5 are plotted in Fig. 6. The residuals are well centered around the origin, with a rather large scatter that can be explained by the poor quality of many orbits due to a lack of observations. The mean values computed with the residuals of Table 5 are $\langle \Delta \rho_{O-C} \rangle = 0''.01 \pm 0''.05$ and $\langle \Delta \theta_{O-C} \rangle = 0^\circ.3 \pm 4^\circ.9$. In both cases, the offsets are much smaller than the standard deviations which provides a validation of our calibration (see Sect. 2.3).

The largest residuals in angular position are reported in Table 4 and give an indication of the orbits that can be revised in the future.

Fig. 5 Distribution of the angular separations of the 1652 measurements of Table 5 (a), and of the differences of magnitude Δm_F actually measured (b). At right (c), plot of Δm_F versus Δm_V , that was reported in the WDS.

Fig. 6 Residuals of the position measurements of Table 5 relative to the published orbits.

6 Conclusion

In this paper, we have presented the numerous measurements that we obtained in 2009-2010, and constituted a significant harvest of results. This validated the technical and data processing investment that we have made in the preceding years. In 2009, we began to use a new EMCCD detector, an ANDOR iXon DV897, whose good sensitivity allowed us to take full advantage of speckle techniques.

In 2009-2010, we obtained 1652 new position measurements of 1569 visual binaries with the 76-cm refractor in Nice. The average accuracy is estimated at $0''.02$ for the angular separation and $0''.6$ for the position angles. We observed faint systems ($m_V \approx 12$) with large magnitude difference (up to $\Delta m_V = 5$). We were thus

able to measure red dwarf stars that had been poorly monitored. We also measured the difference of magnitude of the two components for 1143 objects with an estimated error of 0.2 mag. This work is thus a good contribution to the continuing monitoring of long period visual binary systems, which is important for refining systemic stellar masses. We should also underline that this work is a good illustration of a fruitful collaboration between amateur and professional astronomers.

At the end of 2010, the new speckle camera PISCO2 began operation with a filter wheel, and a remote focusing system. It is a simplified version of PISCO that was first developed in 1993 for the 2-meter Bernard Lyot telescope (Pic du Midi Observatory, France) and had been in operation on a dedicated 1-meter telescope in Merate (Brera Observatory, Italy) between 2004 and 2015 (Prieur et al., 1998, Scardia et al., 2011).

Acknowledgements. We are indebted to the direction of Observatoire de la Côte d’Azur for allowing us to use the 76-cm refractor and to the staff from this Observatory for their technical support. In particular, we thank F. Vakili for lending us the ANDOR DV897 camera. We are grateful to F. Losse for adapting the REDUC software for our needs, and to C. Buil for providing his IRIS software to the amateur community.

We also thank W. Fresquet and J.-M. Laurent from the Andor company for providing us the figures of the quantum efficiency of the DV885 and DV897 detectors. This work has made use of the “Fourth Catalogue of Interferometric Measurements of Binary Stars”

(<http://www.astro.gsu.edu/wds/int4.html>), the “Sixth Catalogue of Orbits of Visual Binary Stars”

(<http://www.astro.gsu.edu/wds/orb6.html>), the Washington Double Star Catalogue maintained at the U.S. Naval Observatory, (<http://www.astro.gsu.edu/wds>), the SIDONIE (Site Informatique des étoiles DOubles de Nice)

<http://sidonie.obs-nice.fr> and the SIMBAD data base (<http://simbad.u-strasbg.fr/simbad>) operated by the *Centre de Données Astronomiques de Strasbourg* (France).

Table 3 Closest binaries measured in 2009-2010 with $\rho < 0''.16$ (i.e. smaller than the diffraction limit).

Table 5 Table of speckle measurements and O-C residuals with published orbits (begin. only). For each object we give its WDS old and new indices (Col. 1 and 2), the name of the discoverer and the components of the system (Col. 3), the magnitudes of the primary (m_{VA}) (Col. 4) and of the secondary m_{VB} (Col. 5) as given by the WDS data base, the BD (Bonner Durchmusterung) entry (Col. 6) from the BD star catalogue of Argelander et al. (1863), the epoch of observation in Besselian years (Col. 7), the position angle θ of the companion (Col. 8), and the angular separation ρ between the two components (Col. 9), the measured difference of magnitudes Δm_F between the two components (Col. 10), some notes in Col. 11 (see text in Sect. 5), and the O-C residuals of our θ and ρ measurements with a computed orbit in Col. 12. **The full table is available in the on-line version.**
