ABSTRACT.

A series of isostructural homo- and hetero-lanthanide coordination polymers of formula $[\text{Ln}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ with $\text{Ln} = \text{La-Gd}$ has been obtained by reactions in water between the lightest lanthanide chlorides and the di-sodium salt of 4,5-dichlorophthalic acid (H_2dcpa). They present particularly high thermal stability for coordination compounds (up to 400 °C). Their luminescent properties have been studied in details. Interestingly an insensitivity to water coordination as well as a very strong effect of optical dilution is observed. Therefore molecular alloys with very high lanthanum concentration have been prepared. Some of them present highly tunable and very intense luminescence. For examples, to the best of our knowledge, $[\text{Sm}_{0.04}\text{La}_{1.96}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ presents one of the highest overall quantum yield measured so far for a Sm^{3+} -based coordination compound ($Q_{\text{Sm}}^{\text{Ligand}} = 9.2\%$) and $[\text{Nd}_{0.03}\text{Sm}_{0.14}\text{Eu}_{0.03}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ is one of the brightest (12 Cd.m^{-2} under 0.75 mW.cm^{-2} UV flux) multi-emissive visible and near infra-red lanthanide-coordination polymer reported to date.

INTRODUCTION.

For more than a decade, lanthanide-based coordination polymers¹ have attracted growing interest, in part because of their unique optical properties.²⁻⁹ Indeed, they can find their applications in various technological fields such as molecular sensing,¹⁰⁻¹⁵ light and display^{6, 16} or fight against counterfeiting.¹⁷⁻²⁰ Therefore, the quest of new lanthanide-based coordination polymers that exhibit original or more efficient luminescent properties is a particularly active field of research.²¹ In order to obtain efficient materials one has to judiciously choose the ligand²²⁻²⁶ and/or the metallic centers.²⁷⁻²⁹ As far as metallic centers are concerned, the synthesis of hetero-lanthanide-based compounds appears as a promising strategy. Indeed it has been demonstrated³⁰ that, in this class of compounds, first described by Zhou *et al.*³¹ in 1994, lanthanide ions distribute randomly over the different metallic centers of the crystal structure so forming molecular alloys³² that allow modulation of the emission color and intensity.³³⁻⁴¹ Of course, the choice of the ligand is also of first importance. Indeed, because of the shielded character of the 4f valence orbitals of the lanthanide ions,⁴² the ligand has deciding influence upon the crystal structure and upon the Ligand-to-Lanthanide energy transfers.⁴³ Therefore, the quest for new ligands that can provide improved luminescent properties is a continuous concern.^{20, 38-39}

As far as potential technological applications are targeted, ligands must be commercially available at low cost and thermally stable. Moreover the synthetic process used for the design of lanthanide-based coordination polymers must be as respectful of environment as possible.⁴⁴

On the basis of these prerequisites, we have undertaken the study of lanthanide-based coordination polymers with 4,5-dichlorophthalate ligand (hereafter symbolized by dcpa^{2-}) (Scheme 1). Indeed, it has previously been demonstrated that this ligand presents an excellent

antenna effect⁴⁵ toward lanthanide ions and leads to lanthanide-based coordination polymers that exhibit very intense luminescence.²⁰

Scheme 1. Schematic representation of 4,5-dichlorophthalic acid hereafter referenced as H₂(dcpa).

Moreover, to the best of our knowledge, there are only a few examples in literature of lanthanide-based coordination polymers with this ligand, and most of them have been obtained by hydrothermal synthesis.^{20, 46-47} In the frame of this study we have prepared, via an environment respectful synthetic process, a family of homo- and hetero-lanthanide-based coordination polymers with general chemical formula $[\text{Ln}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ with Ln = La-Gd (except Pm). These compounds are isostructural to $[\text{Eu}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$,⁴⁶ that has been previously reported. As anticipated, some of them present excellent luminescence properties.

EXPERIMENTAL SECTION

Lanthanide oxides (4N) were purchased from AMPERE Company and used without further purification. Lanthanide chlorides were prepared according to literature.⁴⁸ 4,5-dichlorophthalic acid was purchased from Clinisciences Company and used without further purification. Its sodium salt was prepared as previously described.²⁰

Synthesis of the homo-lanthanide-based coordination polymers.

An aqueous solution of a lanthanide chloride (0.5 mmol in 5 mL) and an aqueous solution of the sodium salt of 4,5-dichlorophthalic acid (0.75 mmol in 5 mL) were mixed and stirred for 30 min at room-temperature. Precipitation occurred. The solid was filtered, rinsed with water and dried at ambient temperature and pressure. All IR spectra were similar and show the characteristic peaks of carboxylate function (1386 cm^{-1} and 1560 cm^{-1}). As a matter of example, IR spectrum of $[\text{Nd}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ is reported in Figure S1. Iso-structurality of the compounds with $[\text{Eu}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ was assumed on the basis of their X-ray powder diffraction patterns (Figure S2).

Synthesis of the hetero-lanthanide-based coordination polymers.

Hetero-lanthanide coordination polymers have been prepared according to the procedure described above for homo-lanthanide compounds, simply replacing the lanthanide chloride solution by a solution of the appropriate mixture of lanthanide chlorides. Iso-structurality of these compounds with $[\text{Eu}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ has been assumed on the basis of their X-ray powder diffraction diagrams (Figures S3-S14). Experimental lanthanides contents were determined by EDS measurements (Tables S1-S12). Random distribution of the different metallic ions over the metallic sites of the crystal structure has been assumed on the basis of previously reported results obtained on similar compounds.^{28, 30, 49-50}

X-ray powder diffraction diagrams.

All X-ray powder diffraction diagrams have been collected with a Panalytical X'Pert Pro diffractometer equipped with an X'Celerator detector. Experimental conditions are: $\text{Cu K}\alpha$ radiation ($\lambda = 1.542\text{ \AA}$), $I = 40\text{ mA}$, $V = 45\text{ kV}$, θ/θ mode. Thermo-dependent X-ray powder diffraction diagrams have been collected with the same apparatus, equipped with an

Anton Parr HTK 1200 furnace, in the same experimental conditions, between room-temperature and 1000 °C under N₂ flux. Simulated, from the crystal structure, X-ray diffraction diagram has been calculated using PowderCell and WinPlotR programs.⁵¹⁻⁵² Fit of the experimental [Eu₂(dcpa)₃(H₂O)]_∞ powder diffraction diagram has been performed using the Fullprof suite⁵³ by Le Bail method⁵⁴ (Figure S15).

Electronic microscopy and Energy Dispersive Spectroscopy (EDS).

EDS measurements have been performed with a Hitachi TM-1000, Tabletop Microscope version 02.11 (Hitachi High-Technologies, Corporation Tokyo Japan) with EDS analysis system (SwiftED-TM, Oxford Instruments Link INCA). Samples were assembled on carbon discs, stuck on a carbon stub. Reproducibility of the elemental analyses has been checked by repeating the measurements several times for several spots per sample. These experiments support the homogeneity of the samples.

Thermal analyses.

Thermal analyses have been performed with a Perkin Elmer Pyris Diamond TGA/TDA analyzer between room-temperature and 950 °C with a 5 °C.min⁻¹ rate in platinum crucibles under N₂ atmosphere. The compound was maintained for 1 h at 950 °C under air atmosphere in order to insure complete combustion.

Optical measurements.

Solid-state emission and excitation spectra have been measured on a Horiba Jobin-Yvon Fluorolog III fluorescence spectrometer equipped with a Xe lamp 450 W, a UV-Vis photomultiplier (Hamamatsu R928, sensitivity 190 - 860 nm) and an IR-photodiode cooled by liquid nitrogen (InGaAs, sensitivity 800 – 1600 nm). Quantum yield measurements

were performed using a F-3018 Jobin-Yvon integrating sphere ($\Phi = (E_c - E_a)/(L_a - L_c)$ where E_c is the integrated emission spectrum of the sample, E_a the integrated “blank” emission spectrum, L_a the “blank” absorption and L_c the sample absorption at the excitation wavelength). The emission/excitation spectra and quantum yield recordings were realized on powder samples introduced in cylindrical quartz cells of 0.7 cm diameter and 2.4 cm height, which were placed directly inside the integrating sphere, or on powder samples pasted on copper plates with silver glue. The luminescence of the La-based microcrystalline powders placed in quartz capillary tubes has been measured at 77 K (Dewar + liquid nitrogen). For the measurements realized at variable temperature (77 K – 300 K), the samples were introduced in an OptistatCF liquid nitrogen cooled cryostat from Oxford Instruments. Longest luminescence decays ($\tau > 10 \mu\text{s}$) have also been measured at room-temperature using this apparatus with a Xenon flash lamp (phosphorescence mode). Shortest luminescence decays ($\tau < 10 \mu\text{s}$) were measured directly with the fluorescence spectrometer coupled with an additional TCSPC module (Time-Correlated-Single-Photon-Counting) and a 300 nm pulsed Delta-Diode. Lifetimes and quantum yields are averages of three independent determinations.

Comparative solid-state luminescent spectra have been measured on the same fluorimeter on powders samples shaped into pellets (1.5 cm²). Spectra were recorded between 450 and 1500 nm with the two detectors (PMT and photo-diode) under identical operating conditions and without turning the lamp off to ensure a valid comparison between the emission spectra.

Appropriate filters were used to remove the residual excitation laser light, the Rayleigh scattered light and associated harmonics from spectra. All spectra were corrected for the instrumental response function.

Solid-state UV-visible absorption measurements have been performed with a Perkin Elmer Lambda 650 spectrometer equipped with a 60 mm integrated sphere.

IR spectra have been recorded with a Perkin Elmer Frontier FT-IR spectrometer equipped with a UATR accessory (Universal Attenuated Total Reflectance) between 650 and 4000 cm^{-1} .

Luminance of the samples expressed in Cd.m^{-2} have been measured with a Gigahertz-Optik X1-1 optometer with an integration time of 200 ms on 1.5 cm^2 pellets under UV irradiation ($\lambda_{\text{exc}} = 312 \text{ nm}$). The intensity of the UV flux at sample location, 0.75(2) mW.cm^{-2} , has been measured with a VilberLourmat VLX-3W radiometer. $[\text{Tb}_2(\text{bdc})_3 \cdot 4\text{H}_2\text{O}]_\infty$, where bdc^{2-} stands for terephthalate, was used as a standard. Its luminance is 142(2) Cd.m^{-2} under these operating conditions ($\lambda_{\text{exc}} = 312 \text{ nm}$; flux = 0.75(2) mW.cm^{-2}).³⁰

The CIE (Commission Internationale de l'Eclairage) (x, y) emission color coordinates⁵⁵⁻⁵⁶ were measured with a MSU-003 colorimeter (Majantys) equipped with the PhotonProbe 1.6.0 Software (Majantys). Color measurements: 2°, CIE 1931, step 5 nm, under 312 nm UV light. $X = k \times \int_{380\text{nm}}^{780\text{nm}} I_\lambda \times x_\lambda$, $Y = k \times \int_{380\text{nm}}^{780\text{nm}} I_\lambda \times y_\lambda$ and $Z = k \times \int_{380\text{nm}}^{780\text{nm}} I_\lambda \times z_\lambda$ with k constant for the measurement system, I_λ sample spectrum intensity wavelength depending, x_λ , y_λ , z_λ trichromatic values $x = X/(X+Y+Z)$, $y = Y/(X+Y+Z)$ and $z = Z/(X+Y+Z)$. Mean xyz values are given for each sample, which act as light sources (luminescent samples). Standards from Phosphor Technology used, calibrated at 312 nm: red phosphor $\text{Gd}_2\text{O}_2\text{S:Eu}$ ($x = 0.667$, $y = 0.330$) and green phosphor $\text{Gd}_2\text{O}_2\text{S:Tb}$ ($x = 0.328$, $y = 0.537$).

RESULTS AND DISCUSSION.

Crystal structure and thermal behavior of $[\text{Ln}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ with Ln = La-Gd (except Pm).

Reactions in water, at room-temperature, between lanthanide chlorides and the di-sodium salt of 4,5-dichlorophthalic acid, lead to microcrystalline precipitates. All the obtained compounds reveal to be iso-structural to $[\text{Eu}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ that has been structurally described previously (CCDC-1551529).⁴⁶ Therefore only a brief structural description, that is necessary for luminescence properties understanding, is given below. This coordination polymer crystallizes in the monoclinic system, space group $P2_1/c$ (N° 14). There are two crystallographically independent Eu^{3+} ions in the crystal structure. Eu1 is eight coordinated by seven oxygen atoms from carboxylate functions that belong to five different ligands and one oxygen atom from a coordination water molecule, that form a slightly distorted trigonal dodecahedron. Eu2 is nine coordinated by oxygen atoms from nine carboxylate functions that belong to six different ligands that form a slightly distorted capped square antiprism (Figure 1). It can be noticed that, in this compound, there is no crystallization water molecule and only one coordination water molecule per formula unit. This low hydration rate is confirmed by thermal analyses. There are three independent dcpa^{2-} ligands in the crystal structure. Their coordination modes are drawn in Figure 1. This figure shows that all the three ligands are polydentate and bind three to four lanthanide ions.

Figure 1. Projection view of an extended asymmetric unit of $[\text{Eu}_2(\text{dcpa})_3 \cdot \text{H}_2\text{O}]_\infty$ (top left); Eu^{3+} ions polyhedrons (top right). Coordination modes of the dcpa^{2-} ligands (bottom). Redrawn from reference 46.

The crystal structure can be described on the basis of inorganic chains made of dimeric Eu1-Eu2 units that spread along the *c*-axis. Inside the dimeric units, the two lanthanide ions coordination polyhedrons share a face ($d_{\text{Eu-Eu}} = 3.8290(4) \text{ \AA}$) and coordination polyhedrons of adjacent lanthanide ions that belong to different dimeric units share a vertex ($d_{\text{Eu-Eu}} = 4.2132(2) \text{ \AA}$) (Figure 2). These inorganic chains are bound to each other by bridging dcpa^{2-} ligands so forming a 2D molecular framework. Shortest distances between lanthanide ions that belong to different inorganic chains lay in the range $5.3093(3)$ - $9.0400(5) \text{ \AA}$ (Figure 2). All the chloride atoms point toward the inter-plane space (Figure 2) and insure the stability of the crystal packing by strong halogen-bonds ($d_{\text{Cl-Cl}} \approx 3.3$ - $3.7 \text{ \AA}$). Shortest inter-metallic distances between lanthanide ions that belong to different molecular layers are about $14 - 15 \text{ \AA}$ that is greater than $10 \text{ \AA}$ which is commonly considered as the threshold above which inter-metallic energy transfer mechanisms become less efficient.^{22, 43}

Figure 2. Left: Projection views of an inorganic chain (top left) and of two adjacent inorganic chains (bottom left). Lanthanide polyhedra are drawn. Only relevant binding ligands are drawn. Characteristic inter-metallic distances are reported. Oxygen atoms of the coordination water molecules are in blue. Right: perspective view of an extended unit cell. Green balls symbolize chloride atoms. Redrawn from reference 46.

From a global point of view, there are 13 lanthanide ions closer than 10 Å from a given lanthanide ion. All of them belong to the same molecular layer (Scheme 2).

Scheme 2. Projection view along the b -axis of a molecular layer. Broken-line circle represents a 10 Å distance from the central Eu1 atom. Redrawn from reference 46. The situation is identical for Eu2 as a central atom.

Thermal analysis under N_2 flux of $[Sm_2(dcpa)_3(H_2O)]_\infty$ (Figure 3) shows the departure of one water molecule around 100 °C (1.8 % - Calc. 2.0 %). The resulting anhydrous compound remains unchanged until 400 °C. Then, the ligands decompose leading to Sm_2O_3 . Thermo-dependent powder X-ray diffraction diagrams have been collected (Figure 3): the crystal structure of the starting compound and that of the anhydrous phase are identical. This is quite rare in lanthanide coordination chemistry. In fact, because of the high structural versatility of lanthanide ions, a change in the hydration rate provokes, usually, a change in the crystal structure.⁵⁷ In the present case, the carboxylate functions are overcrowded which prevents structural reorganization. The robustness of this crystal structure can be related to the strength of the molecular layers induced by the polydentate ligand and to the high density of halogen-bonds between them. It must also be noticed that de-hydrated sample does not re-hydrate when exposed to wet atmosphere.

Figure 3. Top: Thermal analyses of $[\text{Sm}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$. Bottom: Thermo-dependent X-ray diffraction patterns of $[\text{Sm}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ between 25 °C and 950 °C.

This quite high thermal stability, for a coordination compound, makes this series of compounds potentially interesting candidates for technological applications and encouraged us to deeply study their luminescent properties.

Luminescent properties of $[\text{Ln}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ with Ln = La-Gd (except Pm).

Location of the first excited singlet and triplet state of the ligand are of first interest. We have estimated them by referring to the UV-vis absorption edge ($325\text{ nm} \approx 30800\text{ cm}^{-1}$) and to the shortest wavelength of the phosphorescence band at 77 K ($405\text{ nm} \approx 24700\text{ cm}^{-1}$) of $[\text{La}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$, respectively (Figures S16 and S17).⁴³ According to Reinhoudt's empirical rules,⁵⁸ inter-system crossing mechanism is efficient when the gap between the first excited triplet and singlet states is greater than 5000 cm^{-1} . In the present case, the gap is about 6100 cm^{-1} and therefore Ligand-to-Lanthanide ion energy transfer is supposed to involve the excited triplet state of the ligand. It can also be noticed that the observed luminescent lifetime of $[\text{La}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ is very long (124(1) ms) and much greater than what is usually observed for lanthanide-based coordination polymers.^{20, 30}

$[\text{Eu}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$

Among the homo-lanthanide compounds that constitute this family, the most promising one, as far as luminescence in the visible domain is targeted, is the Eu-based one. Its excitation and emission spectra have been recorded at room-temperature (Figure 4). Excitation spectrum shows a broad band centered at 303 nm that can be attributed to ligand $^1\pi \rightarrow ^1\pi^*/^3\pi^*$ transitions and evidences an efficient antenna effect⁴⁵ of the ligand for the Eu-derivative. It also shows excitation peaks that correspond to $^7\text{F}_0 \rightarrow ^5\text{D}_{1-4}$ and $^7\text{F}_0 \rightarrow ^5\text{L}_{6-7}$ 4f-4f transitions. Room-temperature solid-state emission spectra have been recorded under 303 nm and 393.5 nm excitation wavelengths that correspond to the $^1\pi \rightarrow ^1\pi^*/^3\pi^*$ ligand transition and to the $^7\text{F}_0 \rightarrow ^5\text{L}_6$ Eu^{3+} transition, respectively.

Sensitization efficiency (η_{sens}) that corresponds to the efficacy of the Ligand-to-Metal energy transfers, can be estimated, by the following empirical relationship

where Q_{Ln}^{Ln} is the intrinsic quantum yield upon direct excitation of the lanthanide ion and τ_{rad} is the radiative lifetime.⁶¹⁻⁶² For Eu-containing compounds, a simplified relationship allows the estimation of the radiative lifetime:⁶³

$$\frac{1}{\tau_{\text{rad}}} = A_{\text{MD},0} n^3 \left(\frac{I_{\text{tot}}}{I_{\text{MD}}} \right) \quad (2)$$

where $A_{\text{MD},0}$ is equal to 14.65 s^{-1} and corresponds to the spontaneous emission probability of the magnetic dipole $^5\text{D}_0 \rightarrow ^7\text{F}_1$, n is the refractive index and I_{tot} and I_{MD} are the integrated intensities of the $^5\text{D}_0 \rightarrow ^7\text{F}_J$ ($J = 0-6$) transitions and of the $^5\text{D}_0 \rightarrow ^7\text{F}_1$ transition only, respectively. Refractive index n was estimated to 1.50 on the basis of known refractive indexes of similar compounds.^{25, 30} With these assumptions, one obtains $\tau_{\text{rad}} = 2.7(1) \text{ ms}$ and $Q_{\text{Ln}}^{\text{Ln}} = 53(2) \%$ which means that η_{sens} is close to 53 %. Energy transfer mechanisms that govern the luminescence of $[\text{Eu}_2(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$ are reported on Scheme 3.

Scheme 3. Schematic representation of the energy transfer mechanisms that govern $[\text{Eu}_2(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$. The red arrows are the emission in both the visible and the IR (broken arrow) domains. IC, ISC and η_{SENS} stand for Internal Conversion, Inter-Crossing-System and Sensitization Energy processes, respectively. S and T stand for Singlet and Triplet states, respectively.

The sizeable overall quantum yield ($Q_{\text{Eu}}^{\text{Ligand}} = 28(3) \%$) associated with a quite moderate sensitization efficiency ($\eta_{\text{sens}} = 53 \%$) and a quite high intrinsic quantum yield

$(Q_{Eu}^{Eu} = 53(2) \%)^{30, 64}$ strongly suggest that non-radiative de-excitation due to O-H vibrators is weak. Indeed, there is only one coordination water molecule per formula unit in this compound. In order to confirm that it contributes weakly to non-radiative de-excitation we have measured, at room-temperature, excitation and emission spectra of a dehydrated sample of $[Eu_2(dcpa)_3]_{\infty}$ (obtained after heating $[Eu_2(dcpa)_3(H_2O)]_{\infty}$ in a furnace at 200 °C, under N_2 atmosphere, for 2 hours) (Figure S18). Figure S18 shows that both hydrated and de-hydrated compounds exhibit similar luminescent behaviors. Moreover luminescence lifetimes and overall quantum yields are identical. This confirms that non-radiative de-excitation due to O-H vibrators is negligible. This constitutes an asset as far as technological applications are targeted because the user has not to take care of the hydration rate of the compound during the industrial process. This feature is very rare for rare-earth coordination polymers.

Because hydration rate has negligible influence on luminescence properties, only hydrated phases are studied in the following.

$[Sm_2(dcpa)_3(H_2O)]_{\infty}$, $[Pr_2(dcpa)_3(H_2O)]_{\infty}$ and $[Nd_2(dcpa)_3(H_2O)]_{\infty}$

The Sm^{3+} -derivative exhibits luminescence in the visible but also in the infra-red domain. Accordingly, room-temperature solid-state excitation spectrum ($\lambda_{em} = 642$ nm) and emission spectra in both the visible and the IR domains ($\lambda_{exc} = 303$ nm) have been recorded and are reported in Figure 5. Excitation spectrum shows a broad band centered at 303 nm similar to the one observed for $[Eu_2(dcpa)_3(H_2O)]_{\infty}$ that evidences that the ligand act as an efficient antenna for $[Sm_2(dcpa)_3(H_2O)]_{\infty}$ as well. Emission spectrum recorded in the visible domain shows the characteristic emission peaks of Sm^{3+} that correspond to $^4G_{5/2} \rightarrow ^6H_{5/2-13/2}$ transitions ($\tau_{obs} = 0.6(1) \mu s$).⁶⁵ It is noteworthy that emission intensity is so weak that no quantum yield measurement has been possible with our setup. Emission spectrum in the IR

domain also shows the characteristic emission peaks of Sm^{3+} that correspond to $^4\text{G}_{5/2} \rightarrow ^6\text{H}_{15/2}$ and $^4\text{G}_{5/2} \rightarrow ^6\text{F}_{1/2-11/2}$ transitions.

Figure 5. Room-temperature solid-state excitation ($\lambda_{\text{em}} = 642 \text{ nm}$) and emission ($\lambda_{\text{exc}} = 303 \text{ nm}$) spectra in the visible domain of $[\text{Sm}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ (top). Room-temperature solid-state emission ($\lambda_{\text{exc}} = 303 \text{ nm}$) spectrum in the IR domain of $[\text{Sm}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ (bottom).

Room-temperature solid-state excitation and emission spectra of both the Pr- and the Nd-derivatives have also been recorded (Figure 6). Excitation spectra indicate that again the antenna effect is efficient for both compounds.

Emission spectrum of $[\text{Pr}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ shows the characteristic peaks of the Pr^{3+} ion that correspond to $^3\text{P}_{1-0} \rightarrow ^3\text{H}_{6-4}$ and $^3\text{P}_{1-0} \rightarrow ^3\text{F}_{4-2}$ transitions.⁶⁶ It is noticeable that these emission peaks in the visible domain are rarely observed and Pr-based coordination polymers that exhibit such a well-defined emission spectrum are rare.^{38, 64, 67-68} Emission spectrum, in the IR domain, of $[\text{Nd}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ shows the characteristic peaks of Nd^{3+} that correspond to $^4\text{F}_{3/2} \rightarrow ^4\text{I}_{9/2-13/2}$ transitions.⁶⁶

Figure 6. Room-temperature solid-state excitation ($\lambda_{\text{em}} = 641 \text{ nm}$ and 1059 nm for the red and purple solid curves, respectively) and emission ($\lambda_{\text{exc}} = 303 \text{ nm}$) spectra of $[\text{Pr}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ in the visible domain (top) and of $[\text{Nd}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ in the IR domain (bottom).

Brightness enhancement: $[\text{Ln}_{2-2x}\text{La}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ with $\text{Ln} = \text{Pr-Eu}$ (except Pm) and $0 \leq x \leq 1$

It is commonly admitted that inter-metallic energy transfers are less efficient when lanthanide ions are more than 10 Å far from each other.²² As underlined in the structural part, in this family of compounds, there are 13 lanthanide ions closer than 10 Å from a given lanthanide ion and all of them belong to the same molecular layer. Therefore, it is, theoretically, possible to enhance the luminescence intensity by diluting optically-active lanthanide ions by optically inactive ones. In our case we have used La^{III} as optically inactive ion and we have prepared four series of hetero-di-lanthanide coordination polymers with respective general chemical formulas $[\text{Pr}_{2-2x}\text{La}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$, $[\text{Nd}_{2-2x}\text{La}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$, $[\text{Sm}_{2-2x}\text{La}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ and $[\text{Eu}_{2-2x}\text{La}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ with $0 \leq x \leq 1$. Iso-structurality of these compounds with $[\text{Eu}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ has been assumed on the basis of their powder X-ray diffraction diagrams (Figures S3 to S6) and the relative contents of the two lanthanide ions have been estimated on the basis of EDS measurements (Tables S1 to S4).

Emission spectra of the compounds with general chemical formula $[\text{Eu}_{2-2x}\text{La}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ with $0 \leq x \leq 1$ have been recorded ($\lambda_{\text{exc}} = 303 \text{ nm}$) (Figure 7). Their luminance ($\lambda_{\text{exc}} = 312 \text{ nm}$) has been measured as well (Figure S19). Figure 7 shows that luminescence intensity is almost constant whatever x is. This is in agreement with the crystal structure. Indeed, for a given Eu^{3+} ion, if one wants to substitute the 13 nearest neighbors by La^{3+} ions, the x value should be at least 0.93. This is actually what is observed and the luminescence intensity is roughly identical between $x = 0$ and $x = 0.9$. This is interesting as far as potential industrial applications are targeted because lanthanum is much cheaper than europium. This behavior is quite unusual and generally, for La/Eu -based hetero-lanthanide coordination polymers, the decreasing of the number of luminescent centers is not fully

compensated by the decreasing of inter-metallic energy transfers.^{30, 39-40} This suggests that inter-metallic energy transfers are very strong and that particularly high La^{III} content is required to suppress them in this system. Consequently, the dilution of optically active lanthanide ions by optically inactive ones constitutes a very efficient strategy.

Figure 7. Left: room-temperature solid-state emission spectra of $[\text{Eu}_{2-2x}\text{La}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$ with $0 \leq x \leq 1$ ($\lambda_{\text{exc}} = 303 \text{ nm}$). Right: integrated intensity of all the observed Eu^{3+} transitions versus x (step is 0.1). Integrated intensity of $[\text{Eu}_2(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$ is set to 1.

In order to verify this assumption, emission spectra of La/Pr-, La/Nd- and La/Sm-derivatives have been recorded (Figures 8 and 9).

Figure 8. Left: Room-temperature solid-state emission spectra of $[\text{Sm}_{2-2x}\text{La}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$ with $0 \leq x \leq 1$ ($\lambda_{\text{exc}} = 303 \text{ nm}$) in the visible (top) and IR (bottom) domains. Right: integrated intensities of all the observed transitions of Sm^{3+} in the visible and in the IR, respectively, *versus* x (step = 0.1 between $x = 0$ and 0.9, and step = 0.02 between $x = 0.9$ and 1). Integrated intensity of $[\text{Sm}_2(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$ is set to 1.

Figure 8 evidences that the brightness enhancement by dilution is much more efficient for the La/Sm-series than for the La/Eu-series. Indeed the intensity of the luminescence of $[\text{Sm}_{0.04}\text{La}_{1.96}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$ is 432 times and 576 times greater than that of $[\text{Sm}_2(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$ in the visible and in the IR domains, respectively. Enhancement by dilution effect of the Sm^{3+} luminescence has already been reported but with a much lower extend.⁶⁹ This very strong enhancement of the luminescence intensity by dilution effect was unexpected and is, to the best of our knowledge, unprecedented. Overall quantum yield of $[\text{Sm}_{0.04}\text{La}_{1.96}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$ in the visible domain has been measured. It reaches 9.2(2) % which is, for a Sm^{3+} coordination compound, a remarkable value when compared with the literature (Table 1). The luminescence lifetime also increases a lot with a measured value of 0.38(1) ms for $[\text{Sm}_{0.2}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$ compared to 0.6(1) μs for $[\text{Sm}_2(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$. Luminance under irradiation of this series of compounds has also been measured (Figure S20). These measurements shows a very abrupt increase of the luminance with x and luminance for $[\text{Sm}_{0.04}\text{La}_{1.96}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$ is greater than 15 $\text{Cd}\cdot\text{m}^{-2}$.

Table 1. Some overall quantum yields in the visible domain of Sm-based coordination compounds previously reported.

Chemical formula	$Q_{\text{Sm}}^{\text{Ligand}}$ (%)	λ_{exc} (nm)	Reference
$[\text{Sm}_2(\text{cam})_2(\text{bdc})\cdot(\text{H}_2\text{O})_2\cdot\text{dmf}]_{\infty}$	5.2	280	70
$[\text{Sm}(\text{bcpba})(\text{H}_2\text{O})]_{\infty}$	17	259	71
$[\text{Sm}(\text{tfbdc})_{1.5}(\text{H}_2\text{O})_2\cdot\text{H}_2\text{O}]_{\infty}$	0.73	364	72
$[\text{Sm}(\text{tpia})(\text{H}_2\text{O})_3\cdot 5.5\text{H}_2\text{O}]_{\infty}$	1.8	358	73
$[\text{Sm}(\text{dpdc})_{1.5}(\text{ip})(\text{H}_2\text{O})]_{\infty}$	1.76	330	74
$[\text{Sm}_2(\text{mip})_3(\text{H}_2\text{O})_8\cdot 4\text{H}_2\text{O}]_{\infty}$	0.18	325	38
$[\text{Sm}_2(\text{Hshi})_2(\text{dbm})_4\cdot 2\text{dmf}]$	0.8	355	69
$[\text{Sm}_{0.1}\text{Gd}_{1.9}(\text{Hshi})_2(\text{dbm})_4\cdot 2\text{dmf}]$	2.4	355	69
$[\text{Sm}_2(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$	< 0.1	303	This work

Dilution effect for the compounds that constitute the La/Pr and La/Nd series is intermediate between the behavior of the La/Eu-based compounds and that of the La/Sm-based ones (Figure 9). In both cases, maximum intensity is reached for $x \approx 0.9$ but maximum enhancement factor is about 4.9 in the visible domain and about 234 in the IR domain for La/Pr series and is only about 2.3 for La/Nd series.

Figure 9. Room-temperature solid-state emission spectra of $[\text{Pr}_{2-2x}\text{La}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ (top and middle for visible and IR, respectively) and $[\text{Nd}_{2-2x}\text{La}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ (bottom) with $0 \leq x \leq 1$ ($\lambda_{\text{exc}} = 303$ nm). Integrated intensities of all the observed transitions for Pr^{3+} in the visible and in the IR, respectively (top and middle right), and for Nd^{3+} in the IR (bottom right) *versus* x . Integrated intensities of $[\text{Pr}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ and $[\text{Nd}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ are set to 1.

As far as dilution effect is concerned, these four series of iso-structural hetero-lanthanide coordination polymers exhibit drastically different behaviors (Tables 2 and S13).

Table 2. Maximum integrated area of the emission peaks of $[\text{Pr}_{0.04}\text{La}_{1.96}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$, $[\text{Nd}_{0.2}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$, $[\text{Sm}_{0.04}\text{La}_{1.96}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ and $[\text{Eu}_{1.8}\text{La}_{0.2}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ with $0 \leq x \leq 1$ series.

Compound	Visible integrated area*	Infra-red integrated area*
$[\text{Pr}_{0.04}\text{La}_{1.96}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$	4.9	234
$[\text{Nd}_{0.2}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$	-	2.3
$[\text{Sm}_{0.04}\text{La}_{1.96}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$	432	576
$[\text{Eu}_{1.8}\text{La}_{0.2}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$	1.3	-

* Integrated area of the corresponding transitions measured for the homo-lanthanide compounds are set to 1.

Because all the compounds are iso-structural, these results suggest that de-excitation pathways are strongly dependent of the relative energies of the different states of the lanthanide ions (Scheme 4).

Scheme 4. Schematic representation of the energy levels of the dcpa²⁻ ligand and of Pr³⁺, Nd³⁺, Sm³⁺ and Eu³⁺ ions. Broken arrows symbolize transitions in the IR region. IC, ISC and η_{SENS} stand for Internal Conversion, Inter-Crossing-System and Sensitization Energy processes, respectively. S and T stand for Singlet and Triplet states, respectively.

Differences in enhancement factor were expected because non-radiative deactivation process is most often dominated by vibrational deactivation. Indeed the energy gap between emissive and receiving Ln^{3+} states can be bridged by high energy vibrators (O-H, C-H, C=O, C-O, C=C... or their overtones)²³ that are necessary present in coordination compounds. On the other hand, extent of these differences was unexpected. It suggests that relative influence of vibrational deactivation process toward inter-metallic quenching vary in a large extent from a lanthanide ion to another. Because both mechanisms are thermo-dependent emission spectra of $[\text{Ln}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ and $[\text{Ln}_{0.2}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ with $\text{Ln} = \text{Pr}, \text{Nd}, \text{Sm}$ or Eu have been recorded *versus* temperature between 77 K and 300 K (Figures S21 – S24). These measurements evidences that both inter-metallic energy transfers and vibrational de-activation strongly depend on the considered lanthanide ion. However, these results indicate that the influence of the temperature on the emission spectra of the La-doped compounds is unexpectedly weak (fluctuations are only about 10% - Figure S25) when compared with similar coordination polymers.⁴⁹ This could be related to the rigid molecular framework that limits vibrations, and possibly non-radiative de-excitation in this family of compounds.

Investigation of the energy transfers in hetero-lanthanide-based coordination polymers.

Because of this unexpectedly strong dilution effect, a study of the inter-metallic energy transfers that take place in hetero-lanthanide based coordination polymers that involve two optically active lanthanide ions have been undertaken. In order to evaluate the relevance of a "cascade effect" strategy,⁷⁵ Eu-containing series have been studied because $[\text{Eu}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ exhibits the most important overall quantum yield of the homo-lanthanide coordination polymers that belong to this series of compounds. Therefore, $[\text{Pr}_{2-2x}\text{Eu}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$, $[\text{Nd}_{2-2x}\text{Eu}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ and $[\text{Sm}_{2-2x}\text{Eu}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ with

$x = 0.25, 0.5$ and 0.75 have been prepared. Their metallic compositions were determined by EDS measurements (Tables S5 to S7). Their iso-structurality with $[\text{Eu}_2(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ was assumed on the basis of their powder X-ray diffraction diagrams (Figures S7 to S9). Their emission spectra have been recorded in both the visible and the IR domains (Figures S26, S27 and S28 for $[\text{Nd}_{2-2x}\text{Eu}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$, $[\text{Pr}_{2-2x}\text{Eu}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$, $[\text{Sm}_{2-2x}\text{Eu}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ series, respectively). They show similar behaviors and therefore only that of $[\text{Nd}_{2-2x}\text{Eu}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ with $x = 0.25, 0.5$ and 0.75 is described below.

Emission spectra of the compounds that belong to the Nd/Eu-based hetero lanthanide series shows a drastic decreasing of the intensity of the Eu^{3+} emission in both domains when the Nd^{3+} content increases. This suggests strong inter-metallic energy transfers. Inter-metallic energy transfers efficiency (η_{ET}) has been estimated according to the following relationship:⁴³

$$\eta_{\text{ET}} = 1 - \frac{\tau_{\text{obs}}}{\tau_0} \quad (3)$$

where τ_{obs} and τ_0 are the observed lifetimes of the donor luminescence in presence and in absence of an acceptor, respectively. Therefore Eu^{3+} -luminescence lifetimes of $[\text{Nd}_{2-2x}\text{Eu}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ and $[\text{La}_{2-2x}\text{Eu}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ with $x = 0.25, 0.5$ and 0.75 have been measured and compared (Table 3).

Table 3. Eu^{3+} -luminescence lifetimes of $[\text{Nd}_{2-2x}\text{Eu}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ (τ_{obs}) with $x = 0.25, 0.5, 0.75$ and calculated inter-metallic energy transfers efficiency (η_{ET}).

Compound	τ_{obs} (ms)	τ_0^* (ms)	η_{ET} (%)
$[\text{Nd}_{0.5}\text{Eu}_{1.5}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$	0.12(3)	1.42(1)	92
$[\text{Nd}_1\text{Eu}_1(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$	0.09(3)	1.42(1)	94
$[\text{Nd}_{1.5}\text{Eu}_{0.5}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$	0.06(3)	1.42(1)	96

* τ_0 corresponds to the luminescence lifetimes of $[\text{La}_{2-2x}\text{Eu}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ with $x = 0.25, 0.5$ and 0.75

Table 3 shows that inter-metallic energy transfers efficiencies are very strong for all the compounds (Scheme 5). However, Figure S26 evidences that energy that is transferred from Eu^{3+} ions does not efficiently feed luminescent states of the Nd^{3+} ion. Indeed, $[\text{Nd}_{2-2x}\text{Eu}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ exhibits almost no luminescence in the visible domain and a

weaker luminescence, in the IR domain, than the pure Nd^{3+} -derivative. Therefore there is no sizeable "cascade effect" and Nd^{3+} acts essentially as a quencher for Eu^{3+} .

Scheme 5. Schematic representation of the energy transfer that occurs in $[\text{Nd}_{2-2x}\text{Eu}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ with $x = 0.25, 0.5$ and 0.75 . Broken arrows symbolize transitions in the IR region. IC, ISC and η_{SENS} stand for Internal Conversion, Inter-Crossing-System and Sensitization Energy processes, respectively. S and T stand for Singlet and Triplet states, respectively.

Multi-emissive compounds: Hetero-lanthanide-based coordination polymers with a spacer (La^{3+}) and two optically active lanthanide ions ($[\text{Ln}_{0.2-0.2x}\text{Eu}_{0.2x}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ with $\text{Ln} = \text{Pr} - \text{Sm}$ (except Pm) and $0 \leq x \leq 1$.

On the basis of the results described above, we have prepared some hetero-tri-metallic molecular alloys with high lanthanum concentrations (90 %). Indeed, these high relative contents of an optically inactive lanthanide ion should allow the design of multi-emissive derivatives with sizeable brightness.

Therefore compounds with general chemical formula $[\text{Ln}_{0.2-0.2x}\text{Eu}_{0.2x}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_\infty$ with $0 \leq x \leq 1$ and $\text{Ln} = \text{Pr-Sm}$ (except Pm) have been

synthesized (Tables S8 to S10 and Figures S10 to S12). Their emission spectra have been recorded (Figures S29 to S31) and their luminance measured and compared with that of the hetero-di-lanthanide compounds that present identical Eu/Ln ratios but no lanthanum (Figure 10). Their luminescence lifetimes have been measured as well and compared with those of the corresponding Eu/La-based compounds for which the Ln acceptor lanthanide ion has been substituted by lanthanum (Figure S13 and Table S11). Inter-metallic energy transfers efficiencies have been calculated according to relationship (3). Results are gathered in Table 4.

Figure 10. Luminance under UV irradiation ($\lambda_{exc} = 312 \text{ nm}$) of $[\text{Ln}_{0.2-0.2x}\text{Eu}_{0.2x}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$ and of $[\text{Ln}_{2-2x}\text{Eu}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$ with $0 \leq x \leq 1$ and Ln = Pr-Sm except Pm vs x .

Table 4. Eu^{3+} luminescence lifetimes of $[\text{Ln}_{0.2-0.2x}\text{Eu}_{0.2x}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$ (τ_{obs}) with Ln = Pr^{3+} , Nd^{3+} or Sm^{3+} and $x = 0.025$, 0.05 and 0.075 and calculated inter-metallic energy transfers efficiency (η_{ET}).

Compound	τ_{obs} (ms)	τ_0^* (ms)	η_{ET} (%)
$[\text{Pr}_{0.15}\text{Eu}_{0.05}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$	1.03(1)	1.50(1)	31
$[\text{Pr}_{0.1}\text{Eu}_{0.1}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$	1.15(1)	1.47(1)	22
$[\text{Pr}_{0.05}\text{Eu}_{0.15}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$	1.31(1)	1.48(1)	12
$[\text{Nd}_{0.15}\text{Eu}_{0.05}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$	0.86(1)	1.50(1)	43
$[\text{Nd}_{0.1}\text{Eu}_{0.1}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$	1.01(1)	1.47(1)	32
$[\text{Nd}_{0.05}\text{Eu}_{0.15}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$	1.19(1)	1.48(1)	20
$[\text{Sm}_{0.15}\text{Eu}_{0.05}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$	1.18(1)	1.50(1)	21
$[\text{Sm}_{0.1}\text{Eu}_{0.1}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$	1.28(1)	1.47(1)	13
$[\text{Sm}_{0.05}\text{Eu}_{0.15}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$	1.37(1)	1.48(1)	8

* τ_0 corresponds to the luminescence lifetimes of $[\text{Eu}_{2-2x}\text{La}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$ with $x = 0.925$, 0.95 and 0.975

Figure 10 and Table 4 show that dilution by lanthanum provokes a drastic decrease of inter-metallic energy transfers and an important gain in luminance.

Example of an optimized multi-emissive compound: Hetero-lanthanide-based coordination polymer with a spacer (La^{3+}) and three optically active lanthanide ions: $[\text{Nd}_{0.03}\text{Sm}_{0.14}\text{Eu}_{0.03}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$.

Behaviors of all the compounds described above are dominated by the very intense Eu^{3+} luminescence. Therefore, in order to obtain a multi-emissive hetero-lanthanide-based coordination polymer with sizeable emission peaks intensities over the whole emission domain (visible and IR), relative contents of the emissive lanthanide ions must be adjusted. As a matter of example, $[\text{Nd}_{0.03}\text{Sm}_{0.14}\text{Eu}_{0.03}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$ has been prepared (Figure S14 and Table S12). Excitation and emission spectra in both the visible and the IR domains at room-temperature have been recorded (Figures S32-S33 and Figure 11). Emission spectrum (Figure 11) shows a complex emission pattern with more than twenty sizeable emission peaks that can be attributed to Nd^{3+} , Sm^{3+} or Eu^{3+} over all the studied spectral domain (500 nm to 1250 nm). Luminance, measured under UV irradiation ($\lambda_{\text{exc}} = 312 \text{ nm}$; $0.75(2) \text{ mW.cm}^{-2}$) is 12 Cd.m^{-2} . To the best of our knowledge there is no example of lanthanide-based coordination polymer reported to date with such a complex and bright luminescent signature. Moreover this compound composition is not optimized and obviously there are plenty of other molecular alloys exhibiting such excellent properties that can be designed by application of the dilution effect strategy. This can be an asset as far as luminescent bar-codes would be targeted.

Figure 11. Room-temperature solid-state emission ($\lambda_{\text{exc}} = 303$ nm) spectra in both the visible and IR domains of $[\text{Nd}_{0.03}\text{Sm}_{0.14}\text{Eu}_{0.03}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$. $\tau_{\text{Eu}} = 0.93(1)$ ms and $\tau_{\text{Sm}} = 0.39(1)$ ms.

CONCLUSION AND OUTLOOK.

Compounds that constitute this series of iso-structural light-lanthanides-based coordination polymers exhibit very intense and sometimes unprecedented luminescence. Indeed, as a matter of example, $[\text{Sm}_{0.04}\text{La}_{1.96}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$ presents one of the highest overall quantum yield measured so far for a Sm^{3+} -based coordination compound ($Q_{\text{Sm}}^{\text{Ligand}} = 9.2\%$) and $[\text{Nd}_{0.03}\text{Sm}_{0.14}\text{Eu}_{0.03}\text{La}_{1.8}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$ is one of the brightest multi-emissive lanthanide-coordination polymer reported to date (12 Cd.m^{-2} under 0.75 mW.cm^{-2} UV flux). When compared to other rare-earth coordination polymers the $[\text{Ln}_{2-2x}\text{La}_{2x}(\text{dcpa})_3(\text{H}_2\text{O})]_{\infty}$ family shows unexpected physico-chemical behavior: i) their dehydration is not reversible, a very rare feature with lanthanide-based coordination polymers probably due to high rigidity of the lanthanide surrounding ii) their luminescence is almost insensitive to such dehydration or to temperature changes, showing that few non-radiative

de-excitations pathways are active in these samples. Overall, these experimental evidences could be due to a particularly rigid crystal packing that host very few efficient vibrators for non-radiative de-excitation and promote a mineral-like optical behavior with remarkable emission. These optical properties in conjunction with the green synthetic process of the coordination polymers (high yield synthesis in water at ambient temperature and pressure) and their good thermal stability (up to 400 °C) make them attractive candidates as new luminescent taggants.

SUPPORTING INFORMATION
